Solicitors are lawyers, who prepare deeds, manage cases, instruct counsel in the superior courts, and act as advocates in the inferior courts. Their full title is Solicitors of the Supreme Court, and since 1st November 1875 the class includes attorneys, solicitors, and proctors at law. They are deemed officers of court, and the court exercises special jurisdiction over them, committing to prison such of their number as are guilty of misconduct, and in extreme cases 'striking them off the roll'—i.e. erasing their name from the official list of solicitors and so preventing them from practising. Action is now taken on the motion of the Incorporated Law Society, and after a preliminary investigation by that body, which also keeps the roll (Solicitors Act, 1888). Before a person is admitted a solicitor he must be articled to a practising solicitor for a term of five years (reduced to three years in certain cases). He must pass one general (preliminary) and two legal (intermediate and final) examinations. He must also pay about £120 in stamp fees. Solicitors in good practice also require a premium (often as much as £600) from each of their articled clerks. After admission a solicitor must take out an annual certificate enabling him to practise. He must pay for this from £3 to £9 annually; a solicitor of five years' standing may become a barrister on giving one year's notice, passing two legal examinations, and paying certain fees. Penalties are provided for unqualified persons acting as solicitors, and for qualified persons allowing them the use of their name.

Retainer and Authority.—A solicitor is employed by a Retainer (q.v.), which ought to be in writing to avoid after disputes. The exact authority differs in each cause, but includes power to compromise the dispute. If once employed in an action he has authority to manage it to the end. He is liable to his client for gross or crass negligence; he may often, but not always, protect himself by taking (and following) the advice of counsel. A solicitor is not allowed to make a gain for himself (save the ordinary profits of his profession) at his client's expense, so transactions between them, as sales of property, &c., are very narrowly looked into, nor can he generally take a gift from his client. He cannot be a justice of peace in the county where he practises. He has no right of audience in the supreme court save in bankruptcy matters, and that only before the judge in bankruptcy or a divisional court of Queen's Bench. He has certain privileges. Thus, he cannot be made liable for statements honestly made by him as an advocate, and he cannot be forced to reveal written or oral communications made to him by his clients. He is privileged from arrest whilst attending the courts, but this is now of little importance, for it does not extend to punitive attachment.

Remuneration.—The remuneration of solicitors is carefully provided for by various statutes, but often in practice much less than the allowed rate is accepted and much more is exacted. The Solicitors Act, 1876, allows a solicitor to make an agreement in writing for a lump sum or otherwise in lieu of the regular fees. The agreement must be in writing signed by both parties to be binding on the client, but a verbal agreement is binding on the solicitor. The amount agreed on is not payable till the agreement has been examined and approved of by the taxing-master, nor can any action be brought on it. It is enforced by motion before or petition to the proper court. These provisions apply to contentious business. The Solicitors' Remuneration Act, 1881, provides, as regards non-contentious matters, that solicitor and client may agree as to any mode of remuneration. The agreement must be in writing and signed by the party bound by it; it may be enforced by action, and reviewed under any order for taxation. A solicitor winning a case is entitled to two sets of costs—(*a*) those between party and party; and (*b*) those between solicitor and client (extra-judicial expenses in the terminology of Scots law). The first are usually taxed as a matter of course; the other may be taxed on application of either party. A solicitor cannot sue (but may counter-claim) for his costs till one month after he has delivered a signed bill, and except under special circumstances taxation will not be ordered twelve months after delivery of bill. The costs of taxation are paid by the solicitor when more than one-sixth is struck off his charges; if less, the expense falls on the client (see FEES).

Solicitors' Lien.—A solicitor has at common law a twofold lien: (1) a general lien on all deeds and papers which have come to him in his professional capacity—but this merely gives him a right of retention till his claims are satisfied; (2) a particular lien (made more effectual by the Solicitors Act, 1860) on property recovered or preserved by his exertions. It may be actively enforced by means of a charging order, which the court will grant him on such property. Collusive agreements between the parties to deprive him of his rights will be set aside. He is not, however, allowed to retain papers so as to prejudice the trial of an action. He must give them up to be held subject to his lien. In Ireland the law is practically the same on this subject as in England.

Scots Law.—In Scotland the term solicitor is so extensively used as almost to have superseded the old designation of writer. The legal expression is Law-agent. This includes Writers to the Signet, Solicitors before the Supreme Courts, and Procurators in the sheriff courts. They must have served five years as indentured apprentices to a law-agent, have passed examinations in law and general knowledge, and been admitted by the Court of Session. Writers to the Signet, &c. have still certain privileges not here necessary to be discussed. In all cases stamp-duties are paid on admission. Law-agents have a preference, in the nature of hypothec, over expenses of process, and also a right, similar to solicitors' lien, to retain property in their hands. Various acts of sederunt of the Court of Session regulate the fees to be paid to agents. See Cordery's *Law Relating to Solicitors*; and Begg, *On Law Agents.*

Solidungula. See HORSE.

Solidus, a Roman gold coin (see NUMISMATICS, Vol. VII. p. 552). The 'solidus,' or 'solidus aureus,' was adopted by the Franks under the Merovingians and Carlovingians (at 87 to the Roman pound) till the time of Pepin, who suppressed it; but another solidus of silver, or 'solidus argenteus'—the $\frac{1}{20}$th of the libra or pound—which had been used only as a money of account, was soon after made a coin. In later times this 'sol' or 'sou,' like all other coins, underwent an infinity of variations in fineness and value (see LIVRE). On the introduction of the decimal system (1793) into France the sou was abolished, and a piece of five centimes ($\frac{1}{20}$th of a franc) substituted; but the name continued in common use, and the old sous were retained in circulation. The solidus also appears in the *soldo*, which was a coin in use in some parts of Italy, and was substantially the same as the sou. A trace survives in the s. of £ s. d.

Soliman. See SOLYMAN.

Solingen, a town of Prussia, situated 13 miles E. of Düsseldorf and not far from the river Wupper. Ever since the 12th or 13th century it has been famous for its steel and iron ware, especially for sword-blades, helmets, cuirasses, knives, scissors, surgical instruments, &c., which are exported to all parts of the world. These are made by the workmen in their own homes, and some 30,000 persons are employed in this industry throughout the district. Solingen has also iron-foundries, cigar-factories, &c. Pop. (1885) 18,641.

Solis, JUAN DIAZ DE, Spanish navigator, was born at Lebrija, between Cadiz and Seville, near the middle of the 15th century. He was sailing along with Pinzon when the latter discovered (1499) the mouth of the Amazon. In 1515 he himself was sent out, in command of three ships, to find a sea-passage through the American continent that should lead to the East Indies. This led to his discovery of the Paraná (i.e. the Rio de la Plata). But he suffered himself to be drawn into an ambuscade by the warlike Charruas, who dwelt on its banks, and was killed by them (1516).

Solitaire (*Pezophaps solitarius*), a bird allied to the dodo, and like it now exterminated. It lived on the island of Rodriguez, and was described by Leguat, a Huguenot refugee, who in 1691 settled with a small colony on the island. In his *Voyages et Aventures* Leguat describes the solitaire as a large bird, the male sometimes weighing 45 lb.; taller than a turkey, the neck a little longer in proportion, and carried erect; the head of the male without comb or crest, that of the female with something like a widow's peak above the bill; the wings small, and the bird incapable of flying, but using the wings to flap itself or to flutter when calling for its mate, or as a weapon of offence or defence; the bone of the wing thickened at the extremity so as to form a round mass about the size of a musket-bullet; a roundish mass of feathers instead of a tail; the plumage very full and beau-

(*Pezophaps solitarius*).

tiful. He says the bird is called solitaire because it is very seldom seen in flocks, and tells us that the bird is with difficulty caught in the forests, but easily on open ground, because it can be outrun by a man; and that its flesh is very good to eat. In 1865 Edward Newton visited Rodriguez and discovered abundant remains of the solitaire, from which he was able to confirm part of Leguat's description. Since Professor Newton's visit many more skeletons have been discovered, and the osteology of the bird is now well known. Reconstructed skeletons are preserved in the South Kensington Museum, in the Royal College of Surgeons, and in the Museum of the University of Cambridge. The figure here given is derived from a rude cut in Leguat's work. It has been shown that the Dodo (*Didus ineptus*) of Mauritius did not occur on Rodriguez; bones formerly referred to the dodo all belong to the slightly divergent male and female solitaires.

See Strickland and Melville, *The Dodo and its Kindred* (Lond. 1848); also Newton, *Phil. Trans. Roy. Soc.* (Lond. 1869); and *Proc. Zool. Soc.* (1875).

Solmisation. See SOLFEGGIO.

Solo, a term used in musical compositions of several parts, whether vocal or instrumental, to indicate a voice or instrument that is to perform alone or in a more prominent manner, as *soprano solo, violino solo.* The plural, *soli*, is used when two or more voices or instrumental parts are to be performed together, such parts, of course, never being doubled.—A composition for a single instrument accompanied is also termed a solo.

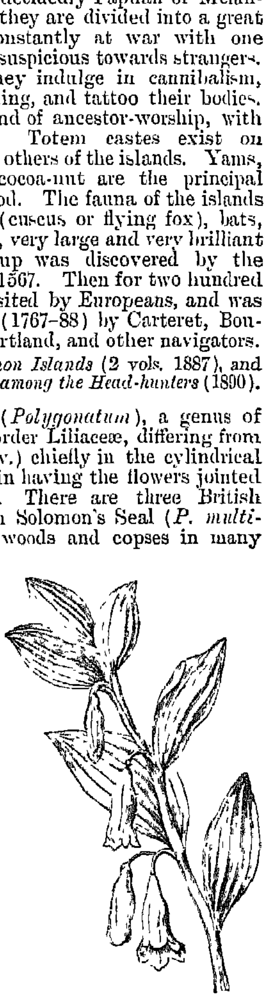
Solofra, a city of Southern Italy, 31 miles by rail E. of Naples, with important manufactures of parchment, &c. Pop. 5178.

Solomon (Salomon, Salomo, Suleimán, Solyman; Heb. Shĕlômô, from *shâlôm*, 'peace,' and so meaning 'the Peaceful,' like Ger. Friedrich), the second son of David and Bathsheba, successor of the former on the throne of the Israelitish kingdom for forty years (1015-977 B.C.). See JEWS, Vol. VI. p. 323. In later Jewish and Mohammedan literature Solomon appears not only as the wisest of men, but as gifted with power to control the spirits of the invisible world. As the builder of the Temple his name is much quoted in the literature of Freemasonry (q.v.). For the so-called Song of Solomon, see CANTICLES; for the other biblical works long attributed to Solomon, see BIBLE, ECCLESIASTES, PROVERBS. The *Wisdom of Solomon*, one of the books of the Apocrypha (q.v.), makes a claim, real or hypothetical, to have been written by Solomon, but from internal evidence it is obviously the work of an Alexandrian Jew, written in the period 150-50 B.C. The book is a hymn in praise of Wisdom—the Wisdom of Proverbs (q.v.), but containing approximations to the doctrine of the Logos (q.v.), and combines the ethical doctrine and speculation of the Hebrews with Platonic and Stoic philosophy. There are commentaries on it by Grimm (1860), Gutberlet (Münster, 1874), and Deane, *The Book of Wisdom* (1881). The *Psalms of Solomon*, also called the Psalms of the Pharisees, were apparently written in Hebrew by a Pharisaic Jew in Jerusalem about 70-40 B.C., and are a protest against modern corruptions. They are an imitation of the canonical psalms, and seem to have been known by the authors of much apocryphal and later Jewish literature. There is an edition of the existing Greek text, with a translation and notes, by Ryle and James (1892).

Solomon Islands, an archipelago in the western Pacific, belonging in part to Germany, in part to Great Britain. The islands lie 500 miles E. of New Guinea, and stretch south-eastwards in two parallel chains for 600 miles towards the Santa Cruz group. The north-eastern chain embraces Bougainville, Choiseul, Ysabel, and Malaita; the south-western Vella Lavella, Kulambangra, New Georgia, Guadalcanar, and San Cristoval. Besides these, which vary between 70 and 110 miles in length, and are 20 to 30 in width, there are a number of smaller ones. They have a total estimated area of 15,000 sq. m.; are nearly all of volcanic formation, there being one active volcano and several quiescent and extinct volcanoes; and are covered from the seashores to the summits of the highest mountains (10,000 feet in Bougainville, 8000 in Guadalcanar, 4100 in San Cristoval) with dense tropical vegetation. There is an extraordinarily heavy annual rainfall, estimated by Dr Guppy at 400 and even 500 inches on the mountains, and 150 on the coasts. The atmosphere is consequently very moist; and the temperature ranges from 75° to 95° F. The people, stated to number 167,000, show decidedly Papuan or Melanesian characteristics; they are divided into a great number of tribes, constantly at war with one another, and are very suspicious towards strangers. Cruel and savage, they indulge in cannibalism, wear little or no clothing, and tattoo their bodies. Their religion is a kind of ancestor-worship, with attendant mysteries. Totem castes exist on Guadalcanar and some others of the islands. Yams, vegetables, and the cocoa-nut are the principal productions used as food. The fauna of the islands includes a phalanger (cuscus or flying fox), bats, gigantic rats and frogs, very large and very brilliant butterflies. This group was discovered by the Spaniard Mendaña in 1567. Then for two hundred years it was never visited by Europeans, and was virtually rediscovered (1767-88) by Carteret, Bougainville, Surville, Shortland, and other navigators.

See Guppy, *The Solomon Islands* (2 vols. 1887), and Woodford, *A Naturalist among the Head-hunters* (1890).

Solomon's Seal (*Polygonatum*), a genus of plants of the natural order Liliaceæ, differing from Lily of the Valley (q.v.) chiefly in the cylindrical tubular perianth, and in having the flowers jointed to their flower-stalks. There are three British species. The Common Solomon's Seal (*P. multiflorum*) is found in woods and copses in many parts of England and in a few places in Scotland. It has a stem about two feet high, the upper part of which bears a number of large, ovate-elliptical, alternate leaves in two rows. The flower-stalks are generally unbranched; the flowers not large, white, and drooping. The roots are knotty, and a transverse section of them reveals characters which the fanciful have imagined represent the impress of the famous seal of Solomon, to which very ancient legends attributed magical properties; the appearances on the cut root being variously described as looking like the 'marke of a seale,' like the magical Pentacle (q.v.), or like Hebrew letters. The Narrow-leaved Solomon's Seal (*P. verticillatum*) is a rare British plant, only found in a few



Angular-stemmed Solomon's Seal (*Polygonatum officinale*).

places in Scotland. The leaves are whorled. The Angular or Sweet-smelling Solomon's Seal (*P. officinale*) is also rare in Britain, and is found only in England. It more nearly resembles the Common Solomon's Seal, but is smaller, and has greenish, fragrant flowers. All these species are common in many parts of Europe. They are very similar in their properties. In America there is a *P. giganteum,* 2 to 7 feet high, and a smaller *P. biflorum.* The young shoots of *P. officinale* are eaten by the Turks like asparagus. The root is white, fleshy, inodorous, with a sweetish, mucilaginous, acrid taste. It contains *Asparagin.* It is a popular application to bruises, to prevent or remove discoloration, and its use is well known to those who are too apt to get a black eye now and then. A kind of bread has been made of it in times of scarcity. The berries are emetic and purgative.

Solon, the famous lawgiver of ancient Athens, was born probably about 640 or 638 B.C., and died about 558 or 559. His father, Execestides, who traced his descent from the royal family of Attica, had squandered an ample fortune. His son became a trader, an occupation which at once brought him wealth and opened up rich stores of observation and experience to his inquiring mind. Doubtless to the wide extent of his travels must be ascribed that unprejudiced political genius by which he was to create a constitution such as had never existed in the world before. He was known also as a writer of graceful and amatory verses, but later his muse soared to a higher strain and sang the triumphs of his legislation and the blessing of the gods on his reforms. One of the finest of his elegies owes its preservation to its being quoted by Demosthenes in his *De Falsa Legatione* (sects. 286-289), 'to show (as he says) how Solon hated fellows like Æschines;' several quotations—one of twenty lines otherwise unknown—occur in Aristotle's *Constitution of Athens* (first edited from a papyrus acquired by the British Museum, by F. G. Kenyon, 1891). The Megarian war (610-600) saw the occasion of Solon's first political achievements. The sarcasms of his stirring Tyrtæan verse induced the desponding Athenians to continue the struggle, and Solon was placed at the head of an expedition to Salamis. Suddenly landing there, he drove out the Megarian garrison, and won the 'lovely island' for Athens; finally the dispute was settled by the arbitration of Sparta in favour of Athens. No story of antiquity is better known than that which tells how Solon attempted to influence the award by the insertion of a line in the *Iliad* (ii. 558), which speaks of the Salaminian Ajax ranging his ships with the Athenians. Solon's influence, already wide, was increased by the strong position he took up a little later in behalf of the Delphic oracle against its oppressors. But the unholy murder of Cylon still rested as a stain upon Athens; Nisæa and Salamis were again lost; and superstitious fears took hold of the people.

But the distress of Attica was not so much religious as economic. The particular grievance which brought matters to a head was the law of debt. The want of a middle class made the contrast between the opulence of the nobility and the indigence of the poor more glaring. A desperate conflict was imminent, when in 594 both parties concurred in inviting the poet and devoted patriot, Solon, to assume the archonship and pacify his distracted country. 'It is not the will of the gods that our city should perish,' sang the poet in noble numbers; 'it is the desire of gain which will bring us to ruin; the thoughts of our leaders are not honest, and their greed will bring great evils upon them. Many of the poor go into foreign lands, sold as slaves, and burdened with shameful bonds.' His first measure was the famous Seisachtheia, and the remedy was severe. A limit was placed on vast accumulation of lands, the person of the debtor was safe whatever his obligations, all debts public and private were cancelled. The reform of the money-standard was made, with the view not so much of assisting debtors by reducing their debts (73 of the old drachmas were recoined into 100 of the new) as of simplifying trade with Asia Minor and opening up new fields for Athenian enterprise. Then the poet sang the end of his labours: 'Many citizens who had been sold into slavery I brought back to Athens their home; some of them spoke Attic no longer, their speech being changed in their many wanderings. Others who had learned the habits of slaves at home, and trembled before a master, I made to be free men. All this I accomplished by authority, uniting force with justice, and I fulfilled my promise.' On laying down office at the end of the year he was requested to reform the entire political constitution of Athens. Solon's object was to destroy the power of the Gentes, and give the poorest class some control over the officers and the law. On the division of the people into four classes, rated according to income, a division which our latest authority, the *Constitution of Athens,* assigns to Draco, his reforms were based. The first class (Pentacosiomedimni) were such as possessed an annual income of not less than 500 medimni of corn, the second class (Hippeis) were rated at 300, the third (Zeugitai) at 200, the fourth (Thetes) consisted of all below the Zeugitai.

On each of the four certain duties were imposed. The three highest provided the land army of Attica, while the Thetes, as rowers in the triremes, formed the most important part of the navy, one day to prove the salvation of Greece and the mainstay of the Athenian empire. The chief offices of state were restricted to the Pentacosiomedimni; the second and third classes were eligible for minor functions. If the Thetes were not admitted to office, their inclusion in the Attic tribes or phylæ, their new right of sitting in the Assembly, electing the public magistrates and passing sentence on their conduct at the end of their year of office, made them practically the sovereign power in the state; and Aristotle traces the swift development of Athenian democracy to the judicial powers received from Solon. The Boulē of 400, another of the great lawgiver's creations, was formed by the election of 100 members from each tribe, and took the place of Draco's council of 401, of which we first learn also in the newly-discovered Aristotelian papyrus. The democratic nature of Solon's Council is proved by its subsequent history. The Areopagus continued as before to be the guardian of the laws and the public morals; it decided also on all grave criminal cases. If he did not originate it, Solon saw the wisdom of preserving and strengthening a body which, by its nature, comprised the best representatives of the highest class of citizens. 'It was,' says Æschylus, 'the bulwark of the land and city, the like of which no man had seen either in Scythia or in the island of Pelops; a council incorrupt, awful, and severe; a watchful guardian over those who slept.' The last of his political reforms was the institution of the Heliæa or popular court of law, the members of which were men of more than thirty years of age chosen annually by lot from every class. The object of its creation was to serve as a balance to the Areopagus, whose judicial supremacy might go too far in the interests of the aristocracy who composed it.

But Solon's work was not yet done. The laws of Draco were not suited to a more civilised age; not only was the severity of punishment for infringement out of all proportion to the offence, but Draco's conception of law appeared inadequate to the comprehensive views of Solon, to whom the function of law was contained not less in directing the citizen's most intimate relations and arrangements than in the guidance of his political and public conduct. Solon's regulations ranged over every province of life. All Draco's laws were repealed except those relating to murder. A limit was placed on the quantity of land that might be held in Attica; no citizen could be enslaved for debt, and absolute freedom in bequeathing property was ensured to any citizen who died childless. Arbitrary power of fathers over their children was restrained and arbitrary disinheritance forbidden. Any citizen who maintained neutrality in a sedition lost his civic status. The Areopagus was empowered to deal severely with luxury in food and dress. No woman might leave home with more than three changes of clothing, or with a basket of more than a cubit's length, and excessive wailing at funerals was forbidden. The laws, inscribed on wood, were placed in the Acropolis, whence they were removed to Salamis during the Persian wars.

The later years of Solon belong more to legend than to history. We are told that he left Athens for ten years, after binding the Athenians by oath to observe his laws till his return. His travels took him far afield. Cyprus, Asia Minor, and Egypt, probably the scenes of his early career, were revisited. Historical investigation may deny the possibility of a dialogue between Solon and Crœsus, but cannot spoil the charm of a story which Herodotus has rendered immortal. The king, then at the height of his prosperity, was said to have asked him who was the happiest man in the world, expecting to hear himself named. Solon first mentioned Tellos, an Athenian who had died for his country at Eleusis. Nor could Crœsus obtain the second mention in the ranks of the happy; that place was assigned to two Argive youths, Cleobis and Biton, to whom the gods had given to die in their sleep as the reward of an act of filial piety. The wrath of Crœsus at the moment was unrestrained, but bitter experience taught him to appreciate the wisdom of Solon, and 'to account a prosperous man happy only when he ended his life as he began it.' Solon's meetings with Anacharsis and with Thales, one of the seven wise men like himself, were among the moral apologues of the ancients. The last years of Solon were passed at Athens, where the wild conflict of parties disturbed the application of the new constitution. He saw the failure of his plans with the deepest distress. His suspicion of his kinsman Pisistratus was justified by the issue. Again he entrusted his warnings to elegiac verse: 'Fools, ye are treading in the footsteps of the fox; can ye not read the hidden meaning of these winning words?' The protest was in vain; Pisistratus seized the government. The opposition of Solon continued; undeterred he laid down his arms before his door, and called heaven to witness that he had stood by his country. Retiring into private life he died soon after the usurpation of Pisistratus, with the last injunction that his ashes should be scattered over the island of Salamis, the 'lovely island' which had been the scene of his earliest exploit.

Solon died the subject of a despotic monarch. His labour might seem wasted, but its eclipse lasted only for a season, and even during the years of the tyranny of Pisistratus its influence was strong. Morally and politically a power among his countrymen, Solon saw that to imprison men in a relentless political machine like Lycurgus, or to humble a refined aristocracy beneath a paid proletariat like Pericles, were policies equally dangerous. His constitution was a graceful compromise between democracy and oligarchy. In poetry he represents a high Ionian type; as a traveller and a soldier his experience of men was large. In the higher realms of constructive statesmanship he rivals the greatest legislators not only of Greece but of the world.

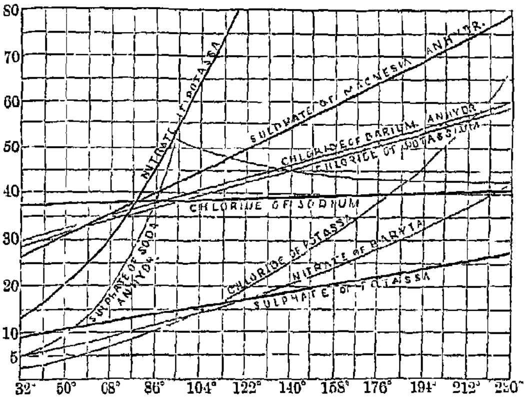
See the Greek histories of Thirlwall, Grote, Curtius, Cox, and Evelyn Abbott; for the poems, Bergk, *Lyrici Græci* (4th ed. 1878); also editions of the *Constitution of Athens*, by Kenyon (1891), G. Kaibel and V. de Wilamowitz-Moellendorff (Berl. 1891); and Eng. trans. by F. G. Kenyon (1891), Thomas J. Dymes (1891), and E. Poste (1891).

Solor Islands. See TIMOR.

Solothurn. See SOLEURE.

Solstice (Lat. *solstitium*, from *sol*, 'sun,' and *sto*, 'I stand'), that point in the ecliptic at which the sun is farthest removed from the equator, and where it is consequently at the turning-point of its apparent course. There are two such points in the ecliptic, one where it touches the tropic of Cancer, the other where it touches that of Capricorn. The former is the summer, and the latter is the winter solstice to those who inhabit northern latitudes, and *vice versâ*.—The term is also employed to signify the *time* at which the sun attains these two points in its orbit, the 21st of June and about the 21st December.

Solution, the liquefaction of a solid or gas by contact with a liquid, the product being a homogeneous liquid called a *solution*. Like many other terms, 'solution' is difficult of exact definition, chiefly because of the loose manner in which it is employed. One liquid is said to *dissolve* in another when the solubility is limited; but when they are mutually soluble to any extent they are said to be *miscible*. Solution depends on the mutual attraction of the molecules of the bodies concerned. A distinction is made between *simple* solution and *chemical* solution. The solution of salt in water is an example of the former; of zinc in sulphuric acid, of the latter. In reality there is only the one form of solution, though it may be preceded by chemical action, as in the conversion of the zinc into sulphate. In some cases a solid is soluble in a liquid to any extent—i.e. the solid may be continuously dissolved in the liquid until the solution becomes viscous or semi-solid. This, however, only occurs with certain amorphous compounds. In the great majority of cases (certainly with all crystalline bodies) there is a definite limit to the solubility, which varies according to the temperature. When a liquid has taken into



]

solution as much of another body as it is capable of dissolving, the solution is said to be saturated. If two or more salts are treated with water at the same time, a proportion of each is dissolved, but the amount of each salt dissolved is less than if the same had been added to the water singly, and is less the greater the number of salts dissolved. As a rule, though not invariably, the solubility increases as the temperature rises. The accompanying diagram shows the unequal solubility of various of the more common salts in water of different temperatures. The *lines of solubility* cut the verticals raised from points indicating the temperature upon the lower horizontal line at heights proportional to the quantities of salt dissolved by 100 parts of water. Solution is of great service in chemical and manufacturing processes. By the difference in the degree of their solubility we can separate one substance from another, and by dissolving a body we can purify it by filtration or crystallisation.

Solway Firth—in its upper part best regarded as the estuary of the river Esk, in its lower as an inlet of the Irish Sea—separates the north-west of Cumberland from the south of Scotland. Its entire length, until lost off Balcarry Point in the Irish Sea, is 36 miles; its breadth for the first 13 varies from 1⅓ to 8½ miles, but afterwards it gradually, although irregularly, increases to 22. The principal rivers flowing into it, besides the Esk, are the Annan, Nith, Dee, and Urr from the north or Scottish side, and the Eden and Derwent from the south or English side. The most striking feature of the Solway Firth is the rapidity with which its tides ebb and flow. The spring-tides are peculiarly swift and strong—the bore rushing in from 3 to 6 feet high, and at the rate of 8 to 10 miles an hour, occasionally inflicting serious damage on the shipping; while after it has retreated great stretches of the bed of the firth are left bare, and in some places one can even cross over from the English to the Scottish shore. The salmon-fisheries of the Solway are valuable. Near Annan the Solway is spanned by a railway viaduct, 1960 yards long, which, originally constructed in 1866–69 at a cost of £100,000, was almost destroyed by floating ice in January 1881, but was reopened to traffic in 1884. Scott paints the scenery of the Solway Firth in both *Guy Mannering* and *Redgauntlet*.

The *Solway Moss* is a district of Cumberland about 7 miles in circumference, lying west of Longtown, and immediately adjoining Scotland. As its name implies, it was once a bog, but is now drained and cultivated. It is historically notable as the scene in November 1542 of the rout of a Scottish host under Oliver Sinclair by a handful of English borderers under Thomas Dacre, the 'Bastard of Lanercost,' and Jack Musgrave of Bewcastle—a disaster which broke the heart of James V. (q.v.), and which forms the theme of an interesting article by Mr W. Manson in *Transactions of the Cumberland Antiquarian Society* (vol. viii., Kendal, 1886). Here, too, on 13th November 1771, an extraordinary disaster occurred. The boggy ground, surcharged with moisture—the effect of heavy rains—rose, swelled, and burst like a torrent, sweeping along with it trees and houses, and destroying some thirty small villages.

Solyman, or SULEIMAN II., surnamed 'The Magnificent,' the greatest of the Ottoman sultans, was born in 1496, and at twenty-four succeeded his father Selim I. His first care was to refund a large amount of property that had been unjustly confiscated, his next to remove incompetent and corrupt officials, and to begin a comprehensive scheme of internal reform. But before this task was completed he led an army into Hungary, to extort the tribute that its king refused to pay him at his accession. He took Schabatz, Semlin, and Belgrade (1521), and left Turkish garrisons in them. Then he carried a very formidable army to attack the Knights of St John at Rhodes; they had beaten off a Turkish army with a loss of 25,000 forty years previously. On this occasion they inflicted a loss of nearly four times that number upon the Turks before surrendering (1523) after a six months' siege. The following three years were devoted by Solyman to the internal government of his domains. But in 1526 he again led a force of 100,000 men into Hungary, slew King Louis at Mohacs (29th August) and all but annihilated his army, and pushing on farther captured both Buda and Pesth. He was recalled by tidings of an outbreak in Asia Minor. By 1529, however, he was back again in Hungary, ostensibly as the supporter of John Zapolya, who claimed the crown of Hungary against Ferdinand of Austria. Ferdinand was turned out of Buda and driven back into Vienna, which city the sultan besieged (September to October). After delivering a desperate assault, which cost him 40,000 soldiers, he was obliged to retreat without taking it. Returning home he directed his arms against Persia, and conquered (1534) large portions of Armenia and Persia proper, including the strong cities of Tabriz and Bagdad. At the same time he sent out his fleets against the Christian powers of the Mediterranean, and his lieutenants (Barbarossa, Piyala, and others) conquered the whole of the north of Africa except Morocco—Egypt was his already. But Tunis was recovered by Charles V. in 1535. In 1542 the widow of John Zapolya appealed to Solyman to aid her son against Ferdinand. Solyman allowed the young prince to retain Transylvania, but Hungary he kept for himself. Six years later a truce was made between the Turks and imperialists, Solyman being left in possession of the greater part of Hungary and Transylvania, and being granted a yearly tribute of 50,000 ducats. In 1565 the fleet and army of Solyman sustained a severe reverse in an unsuccessful attempt to reduce Valetta, the headquarters of the Knights of St John in Malta. And in the following year, whilst besieging the small fortress of Szigeth in Hungary, the great sultan died (4th September). Solyman is equally renowned as a lawgiver and just ruler, as a patron of learning and an encourager of the fine arts.

Soma is the name of a god worshipped by the Aryan Indians in Vedic times, as well as of a certain plant, and its juice used for the preparation of an intoxicating drink. The word is most probably derived from the root *su* (cf. ὕω), 'to press out,' 'distil,' and thus originally meant 'extract.' The Soma cult, with its copious libations and potations of the sacred beverage, is not confined to India, but was already a prominent feature of the religious system of the Indo-Iranians; the old Persian *haoma* sharing all the characteristics and uses of the Indian *soma*. In his divine form Soma is conceived of as a powerful deity of a fiery and luminous nature, the inspirer of heroic deeds of arms, as well as of the flights of fancy and song, the bestower of health, long life, and even immortality. Indeed, in accordance with his physical origin, this fiery deity is at the same time the *amrita* (ambrosia), or the drink of immortality, alike for gods and men. At the Soma sacrifice, therefore, not only are libations of Soma juice made to the principal deities, but the sacrificer himself and the priests freely partake of the potent liquor. Among the celestials it is especially the god Indra, the *Jupiter pluvius* of the Vedic pantheon, with whom Soma stands in close connection; the ever welcome draughts of the fiery juice supplying him with the requisite strength and nerve for battling with the demons of drought and darkness. In the later Vedic literature Soma appears completely identified with the moon; this luminary in its varying phases being considered as the vessel containing the celestial supply of Soma juice on which the gods subsist, and which consequently requires periodical replenishment. Whilst this notion was formerly regarded as merely a secondary development of Indian mythology, recent research suggests that the identity of Soma with the moon may after all hold good for the whole of the Vedic times, if not also for the Indo-Persian period. The conception of a heavenly receptacle of the Soma juice forms, however, only one part of the Vedic Soma myth, which, indeed, pictures the god in all the various forms which the earthly Soma undergoes, from the time when the golden-stalked plant is brought down from its mountain-home till the final consummation of the Soma cup, as the 'supreme offering.' For his regeneration Soma descends periodically to the earth, either in the shape of the heavenly plant carried off by an eagle (probably the lightning) from his jealous demon keepers, or in the form of the fiery germ received by the cows or waters of heaven, and carried down by them to the earth, there to be taken up and matured by the plants springing up luxuriantly after the rains. The question as to what particular plant may claim to be regarded as the true Soma or 'moon-plant' is surrounded with difficulties; probably, however, the stems of several varieties of Asclepiads, akin to the common milk-weed, such as *Asclepias acida*, *Sarcostemma brevistigma* or *viminale*, and *Periploca aphylla*, all of them containing a rich, milky juice, were used for this purpose. The Brahmans of the Deccan, as well as the Parsees or fire-worshippers of Kerman and Yezd in Persia, and those in Bombay, make use to this day of different species of this genus. The Soma sacrifice, as practised in the later Vedic times, is surrounded by a complicated ceremonial of great solemnity. Sixteen priests officiate at its performance. A feigned purchase of Soma plants for a cow, at the conclusion of which the low-caste vendor is beaten off the sacrificial ground with sticks, is apparently a symbolical representation of the acquisition of the Soma by the gods from the demons. The bundle of Soma plants is henceforth treated as the veritable King Soma: he is driven in a car in state to the sacrificial hall, where he is placed upon a throne-seat, a guest-meal being then provided for him, and a solemn covenant concluded between him and the sacrificer. The Soma juice is subsequently obtained by means of two pressings; and the libations are made at three different services, the morning, mid-day, and evening service. The ninth book of the *Rigveda-sanhitâ* consists of over a hundred hymns composed for the special purpose of being recited in honour of *Soma pavamâna*—i.e. of the Soma juice, whilst fermenting and 'clarifying.' Animal offerings form a necessary part of the Soma sacrifice.

For further details, see Eggeling, *Translation of the Satapatha Brâhmana*, vols. ii. and iii. (in the Clarendon Press series of Sacred Books of the East). On the divine personality of Soma, cf. J. Muir, *Original Sanskrit Texts*, vol. v.

Somali-land, an eastern projection of Africa, washed by the Gulf of Aden on the north and by the Indian Ocean on the south-east; the western boundary may be defined by a line drawn south from Zeyla, on the Gulf of Aden, through Harar to the River Jub or Juba. Besides this river the only considerable stream is the Webi-Shebeyli, which, however, does not reach the Indian Ocean, its waters being lost in the sands near the southern extremity of the region. The country is apparently an undulating plateau, in very many parts parched and barren; though in the rainy seasons (two of two or three months' duration each) numerous swamps are formed. Game and wild animals—elephant, hippopotamus, lion, leopard, crocodile, antelopes, water-buck, monkeys, ostriches, vultures, marabout storks, &c.—are generally plentiful. The vegetation is on the whole arid, though in suitable localities there grow luxuriant grasses, mimosas, acacias, gum-bearing trees, palms, sycamores, cactus, aloe, and others. The inhabitants, the Somal, numbering probably half a million, are for the most part a pastoral people, who lead the life described as characteristic of the Old Testament patriarchs. They have herds of camels, sheep, and oxen, and keep horses and goats. Fond of liberty and warlike, they are ruled by a number of petty chiefs, and are jealous of strangers entering their territory (on which account it is almost wholly unknown); nevertheless, they are said to be a light-hearted, merry, affectionate race, though quick-tempered, and in their wrath savage and cruel. They are Mohammedans in religion. Ethnically they belong to the Hamitic stock, and are closely akin to the Galla and the Abyssinians; but they are not a pure race, for there is a strong blending of Semitic (Arab) blood in them, and easily discernible traces of Negro as well. What trade there is in the natural products (myrrh and frankincense, hides, ostrich-feathers, coffee, salt, &c.) finds an outlet through the ports on the coast, principally through Berbera and Zeyla on the shore of the Gulf of Aden.

The Somali coast protectorate of Britain extends from Ras (Cape) Jibuti, on the west of Zeyla, to Ras Hafun, some considerable distance south of Cape Guardafui, and includes the fortified towns of Zeyla, Berbera, and Bulhar, and the unfortified Karam. The cattle, sheep, hides, ostrich-feathers, gums, &c. exported from these seaports reach an annual value of £540,000. This district was annexed by Egypt in 1875, but has been under British protection since 1884.

See F. L. James, *The Unknown Horn of Africa* (1888); Captain F. M. Hunter, *Somali Grammar* (Bombay, 1880); Paulitschke, *Beitrage zur Ethnographie der Somal*, &c. (Leip. 1886); Révoil, *La Vallée du Darror* (1882), and *Faune et Flore des Pays Çomalis* (1882); and Brichetti-Robecchi, *Boll. Soc. Geog. Ital.* (vols. iii. and iv.).

Sombreréte, a town of Mexico, 105 miles NW. of Zacatecas, in a mountainous district celebrated for its rich silver-mines. Pop. 5200.

Sombrero (Span., from *sombra*, 'shade'), a broad-brimmed felt hat, originally Spanish, but common throughout North and South America.—For the hat-shaped Sombrero island, and for Sombrerite, see APATITE.

Somers, SIR GEORGE, an English navigator, born at Lyme Regis in 1554, whose shipwreck on the Bermudas (q.v.) led to their colonisation from Virginia by him in 1611, when, however, on 9th November he 'dyed of a surfeit in eating of a pig.'

Somers, JOHN, LORD, Whig statesman, was born at Worcester, an attorney's son, on 4th March 1652, and in 1667 entered Trinity College, Oxford, in 1669 the Middle Temple, being called to the bar in 1676. Associated with the 'Country party,' he was one of the counsel for the Seven Bishops (1688), and from the Revolution onwards took a prominent part in politics, being returned for Worcester to the Convention parliament, and successively made Solicitor-general, Attorney-general, and Lord Keeper of the Great Seal, until in 1697 he became Lord Chancellor, and was raised to the peerage as Baron Somers of Evesham. He was William's most trusted minister, and as such was the object of frequent attacks, one of which in

1700 resulted in his being deprived of the seal, and another in 1701 in an impeachment by the Commons, rejected, however, by the House of Lords. He returned for two years to power as President of the Council (1708–10), and died of apoplexy, 26th April 1716. The *Somers Tracts* (16 vols. 1748), a valuable collection of state papers from his library, were re-edited by Sir Walter Scott (13 vols. 1809-15).

Somersby, a pretty village of Lincolnshire, stands on the Wolds, about 7 miles E. by N. of Horncastle and the same distance NW. of Spilsby, and is celebrated as the birthplace of Tennyson. The rectory, in which he was born, is an ordinary country parsonage, not without touches of picturesqueness. Pop. 43. Illustrations will be found in J. C. Walters, *In Tennyson Land* (1890).

Somerset, DUKES OF. See SEYMOUR. For the Earl of Somerset, see OVERBURY.

Somerset House, London, fronting both on the Strand and on the Thames Embankment, stands on the site of a palace built by the Protector Somerset about 1549, which fell to the crown on Somerset's execution. The original edifice was pulled down and rebuilt in 1776-86, after designs by Sir William Chambers, in the Palladian or Italian style. The building accommodates the offices of the Audit and Exchequer, Inland Revenue, Wills and Probate, and the Registry-general of Births, Deaths, and Marriages for England and Wales. The east wing, built in 1828, accommodates King's College and School.

Somersetshire, an important maritime county in the south-west of England, is bounded on the N. and W. by the Bristol Channel (the ancient 'Severn Sea'); by Gloucestershire, Wiltshire, and Dorsetshire on the NE. and E.; and by Devonshire on the S. and SW. In form oblong, with a length of some 80 miles and a breadth of 36, it has an area of 1640 sq. m. Pop. (1801) 273,577; (1841) 435,599; (1881) 469,109; (1891) 484,326. The surface is exceedingly diversified, with every variation from lofty hills and barren moors to rich vales and wide marshy levels, whence the sea is banked out by an elaborate system of dykes and sluices. The frontier between Somerset and the adjacent counties consists for the most part of a broken and picturesque hilly district. Sundry ranges of hills, running east and west, give to the county its leading physical characters. Chief of these is the Mendips (q.v.), which stretch from near the city of Wells to the coast at Brean Down, with a seaward continuation in the islets of the Steep and Flat Holms. South of the Mendips lies the great alluvial plain of central Somerset, broken by the line of the Polden Hills, which rise from the marshy levels like a long low island some 300 feet. Still farther south, beyond Taunton, are the Blackdown Hills, about twice this elevation, and continuing eastward into the broken upland which once formed part of the ancient forest of Selwood, where Somerset, Wilts, and Dorset meet. To the north-west of Taunton, bordering Bridgwater Bay, are the Quantock Hills, rising at Will's Neck to 1262 feet; and west, again, is the wild district of Exmoor Forest (q.v.), partly in Devon, but mainly in Somerset. At several points on the inland borders heights of between 800 and 1000 feet are attained. The only two rivers of commercial importance in Somerset originate elsewhere. The Bristol Avon, which forms the boundary of the county for many miles, rises near Badminton in Wilts, and enters Somerset near Bath. The Parret rises near South Perrot in Dorset, and drains the middle of the county: it is tidal to beyond Bridgwater, and is one of the streams possessing a tidal 'bore.' These two rivers with their feeders discharge the bulk of the waters of the county. Between them the chief independent streams are the Axe and the Brue, south of the Mendips, and the Yeo, north. The Exmoor district is drained by the Exe, which falls into the sea at Exmouth, and by the Devonshire Axe, which rises, however, in Dorset.

The geological features of the county are singularly varied, ranging from Devonian upwards. Carboniferous strata occupy a wide area in the north, east, and centre, and are worked for coal in the Radstock and Nailsea basins of the Bristol coal-field; while the mountain-limestone is largely developed in the Mendips and near Bristol, where it is traversed by the magnificent gorge of the Avon. Oolitic rocks stretch along the east of the county from Yeovil to Bath, and in the neighbourhood of the latter city are extensively worked for the production of the well-known Bath building-stone; while other beds are wrought at Doulting and Ham Hill. Liassic rocks are well developed, chiefly in the central region, though in somewhat scattered fashion. Triassic rocks occupy a very wide area in the west of the county, ranging with breaks from Wellington to Bristol; and there is Greensand on the extreme south-west. Extensive caverns in the limestone of the Mendips have yielded abundant remains of prehistoric mammalia, with relics of their human contemporaries. The Mendip mining area is one of the oldest in the kingdom, for lead was raised there before the advent of the Romans, and the iron ores of the Brendon Hills, on the eastern flank of Exmoor, were also worked at a very early date.

The agriculture is mainly pastoral, the proportion of tillage to grazing and dairy-farming being small, though the low lands generally are exceedingly fertile—the fertility of the valley of the Tone, near Taunton, having passed into a proverb. Even this is exceeded by the luxuriance of the marshy meadows of the Bridgwater Level, which are, however, liable to be flooded, and are maintained against the sea at considerable expense. The orchards of Somerset are second only to those of Devon in area and importance, and cider is largely made; while Cheddar cheese has a national reputation. Manufactures maintain considerable importance, particularly in textiles (chiefly woollens), potteries, paper-making, and gloving; and though the city lies mainly on the Gloucestershire side of the Avon, and is a county to itself, Somerset may fairly claim a share also in the commercial importance of Bristol (q.v.).

The bone-caves of the Mendips have supplied evidence of the presence in Somerset of neolithic if not of palæolithic man; and there is abundant evidence of the occupation by strong and comparatively civilised tribes prior to the Roman invasion in the remains of important hill fortresses (Hamdon, Castle Neroche, Dolbury, Maesbury, Worlebury, Cadbury), while the megalithic circles and other remains at Stanton Drew are among the most interesting in the kingdom. Immediately prior to the Roman invasion under Claudius the north of the county was inhabited by the Belgæ, while the territory of the Dumnonii seems to have extended over the Devon border to the marshy and central district, which probably formed a strong natural frontier, though there is evidence that part of this area had been embanked against the sea in pre-Roman times. The Mendips must, however, have formed part of the earliest Roman conquest, as pigs of lead have been found there bearing the names of Claudius, Britannicus, and Vespasian. Somerset became one of the chief seats of Roman civilisation in Britain. Bath (q.v.), as the city of *Aquæ Solis*, was a centre of refinement and luxury. The remains of the baths built by the Romans for the reception of the famous mineral waters are among the most important relics of the Roman period in England. But the impress of the Roman has been left in nearly every part of the county—in villas, roads, pottery kilns, interments, and coins; while Ilchester, like Bath, was a Roman city. Tradition claims for Glastonbury (q.v.) the honour of being the first seat of Christianity in Britain. Under the Saxons the district became known as the home of the Sumersætan, and took its present name, the origin of which is disputed. Part first came under Saxon sway in 658, but its inclusion in Wessex was not complete until 710, when Gerente was defeated by Ine, who made Taunton (q.v.) his chief fortress, and founded the cathedral of Wells (q.v.), which became the seat of the bishopric of the Somersætas (since Bath and Wells) in 909. Somerset was the last home of Saxon freedom when Alfred took refuge at Athelney, defended by trackless marshes. It was at Wedmore that Alfred made his treaty with Guthrum, though the claims of Edington to be the Æthandune where he won his most memorable victory are doubtful. In the wars of the Roses Somerset was in the main Lancastrian; in the wars of the Commonwealth it was chiefly parliamentarian, and the stout defence of Taunton first made famous the name of Admiral Blake. The county was also the centre of Monmouth's operations; and it was chiefly Somersetshire men who fell at Sedgemoor (1685). The county has two cities—Bath and Wells; parliamentary boroughs in Bath and Taunton; an important manufacturing port in Bridgwater; one of the finest watering-places on the western coast in Weston-super-Mare; manufacturing towns in Frome, Yeovil, Shepton Mallet, and Wellington; and seven county parliamentary divisions.

Somers' Islands. See BERMUDAS.

Somerville, a city of Massachusetts, a suburb of Boston, 2 miles from the central station. It has many handsome residences, contains tube-works, bleaching-works, and large slaughter-houses, and manufactures also flour, leather, iron, oil, bricks, &c. Pop. (1880) 24,933; (1890) 40,152.

Somerville, MRS MARY, a lady famed for her mastery of mathematics and physical science, was the daughter of Admiral Sir William Fairfax, and was born on 26th December 1780 at Jedburgh in the manse of her uncle and future father-in-law, Thomas Somerville, D.D. (1741–1830), the author of *My own Life and Times.* She was brought up at Burntisland and Edinburgh, amid somewhat narrow family circumstances. It was in an algebraic sum in a magazine of fashions that she first made acquaintance with the subject that most engrossed her attention in after-life. In 1804 she married a cousin, Captain Greig, of the Russian navy, Russian consul in London. He died in 1806, and it was not till her return north as a widow that she was free to buy the books she wanted, and to study the subject that most interested her. In 1812 she married another cousin, Dr William Somerville, inspector of the army medical board, who entered warmly into all her ideas. They removed to London in 1816, where Mrs Somerville went much into society, and became known as possessed of scientific interests and gifts. In 1823 she was invited by Lord Brougham to try to popularise for the English public Laplace's great work, the *Mecanique Celeste;* and the *Celestial Mechanism of the Heavens* (1830) was received with the greatest admiration. Mrs Somerville was awarded a royal pension of £300 in 1835. Other works by her were *The Connection of the Physical Sciences* (1835), *Physical Geography* (1848), and *Molecular and Microscopic Science* (1866). Mrs Somerville, who for many years resided in Italy, died at Naples, 29th November 1872. An autobiography, edited and supplemented by her daughter, was published in 1873. After her is named Somerville Hall, a college for women at Oxford (1879).

Somme, a river of northern France, rises not far from St Quentin in the dept. of Aisne, flows in a south-west, then north-west direction, and after a course of 150 miles falls into the English Channel not far from St Valéry. It is navigable for vessels of 300 tons up to Abbeville (q.v.), and its upper course is canalised.—The *département* of Somme, in the north of France, formerly part of the province of Picardy, touches the English Channel on the north-west. Area, 2378 sq. m. The dept. is level, very fertile, and amongst the best cultivated districts of France. Much cider is made and poultry reared. The textile industries (wool, cotton, linen, hemp, silk spinning, and the weaving of mixed stuffs, cloth, velvet, carpets) give the principal mechanical employments; but there are also large iron-foundries, lock, soap, candle, chemical, paper, and beet-root sugar factories, distilleries, and breweries, employing in all nearly 70,000 hands. There are the five arrondissements of Abbeville, Amiens, Doullens, Montdidier, and Péronne; chief town, Amiens. Pop. (1872) 557,015; (1891) 546,495.

Somnambulism (Lat. *somnus*, 'sleep,' *ambulo*, 'I walk') is a disorder of sleep. It is symptomatic of more or less activity in some of the psychical and motor areas of the brain, while the centres that preside over consciousness are slumbering soundly. There are different forms, as sleep-crying, sleep-talking (somniloquy), and sleep-walking. These all involve sensori-motor acts.

Sleep-walking is closely related to hysteria and epilepsy, and it occasionally alternates with these and allied diseases. It occurs mostly in youth, affecting males and females in almost equal proportion; commonly, although not invariably, it disappears when adult age is attained. It is met with chiefly in persons of nervous temperament, and in those who have an inherited proclivity to neurotic disease. The exciting causes embrace mental excitement, overwork, fright, bodily fatigue, hepatic and digestive disorders, worms, and an overloaded bladder, and in females uterine and ovarian troubles. Sleep-walking is one of the neuroses of deep sleep. It occasionally presages graver maladies; generally these may be prevented by suitable treatment. It is important to recognise that it is a pathological state, and that no one who is in perfect health walks in his sleep. Sleep-walking is an acted dream, which generally supervenes when sleep is deepest—often during the first deep sleep. The dreamer usually stages it so precisely that he is able to act it with admirable exactness. In the first visitation the dream may be simple, and merely impel the sleeper to rise from bed to walk round the room and then return to bed. Eventually the dreams become more elaborate, and may embrace many complex operations, in which the individual has to elude articles of furniture, unlock doors, open windows, walk along dangerous roofs, or beside the edge of precipices—in short, perform feats he could not possibly execute in his waking moments.

Sleep-walkers have achieved the most diverse exploits without awaking. They have swum across rivers, thrashed corn, ridden on horseback, and even transacted their usual daily work. They are oblivious to danger, and untrammelled by fear; this, combined with an exaltation of muscular sense, enables them to effect their movements precisely and quickly. Their feats, however, are sub-conscious, and not, as it is popularly supposed, superhuman. Their senses, which are not connected with the dream, slumber; they do not see, hear, or smell, so they perform with their eyes shut as well as open, and they may be shaken, and may themselves cough and sneeze without being awakened. A certain degree of anæsthesia appears to render them insensitive to pain. After the dream-act is ended the sleeper returns to bed, to sleep until the usual hour for rising, and when he awakes he either does not recollect anything about his escapade, or remembers it only as a dream. Most frequently he recollects it in a subsequent sleep-walk, just as some dreams are only remembered in recurring dreams. Sleep-walking leads the actor into situations which endanger life, and annually many deaths are recorded from fatalities so arising. If the sleep-walker be awakened at a critical moment, coolness and precision are replaced by agitation and fright, and movements become halting and clumsy, and accident usually follows. Many tragedies have been enacted in this state, and these are of great forensic interest. From every point of view sleep-walking is a source of much anxiety to the afflicted and his relatives.

A sleep-walker found in his wanderings ought not to be awakened, but led back to bed as gently as possible. Abrupt awakening may give rise to shock, and may mark the onset of grave nervous disorders. Whilst it is always advisable to seek medical advice, it may be indicated that the general health should be attended to, so that it may be improved; and all exciting causes should be remedied or avoided, as, for example, all undue excitement and fatigue of mind and body. The sleeping conditions require consideration; in some cases it is advisable that some one should sleep in the same room. Occasionally, it is advantageous to awaken the sleeper at the end of the first hour of sleep, when it is deepest, to prevent it becoming too profound. Hypnotism is sometimes called artificial somnambulism. See the works and articles cited at SLEEP.

Somnath, an ancient town of Gujarat, in India, is situated on the south-west coast of the peninsula of Kathiawar, with a population of 6644, mostly Mohammedans. The town is defended by a strong fort and by a trench cut in the solid rock. It contains many ruins and memorials of Krishna, who died and was buried close by. Not far from the town stand the ruins of the celebrated Hindu temple of the idol Somnath. Its great sanctity and the fame of its enormous wealth attracted the imagination and avarice of the sultan Mahmud of Ghazni (1024). He took the temple after a desperate defence by its guardians, destroyed the sacred idol, and carried off its stores of jewels, and (according to the tradition) the wonderful temple gates. It is, however, more than doubtful whether the 'gates of Somnath' which Lord Ellenborough brought back from Afghanistan in 1842, and purposed to have restored to Somnath after having carried them in solemn procession through great part of Northern India, really are the gates of the ancient temple beside the Arabian Sea in Kathiawar. The gates that were brought from Afghanistan, and eventually placed in the arsenal of Agra, are made of cedar and richly carved, and measure 11 feet in height by 9 feet 6 inches in width.

Sonata, a musical composition usually of three or four movements, designed chiefly for a solo instrument. Before the 17th century the overwhelming tendency of musical development had been to increase by every possible device the vocal resources of the art, a culminating point being reached in the works of Palestrina and the school of madrigal writers. Instrumental music had been represented for the most part by dance tunes which had no great formal development, whilst the early attempts at opera relied almost entirely on the vocal element for their effect. In fact, abstract music, independent of external impressions and deriving all its interest from intrinsic qualities, was up to this time unknown. Some very early sonatas, published at Venice in 1624, consisted of a single movement; but the principle of a succession of contrasted movements, as in the case of the suite, was eventually established, all existing musical forms being pressed into service to secure its fulfilment. Thus, the 'first movement' consisted of a kind of canzona, imitated from a choral form kindred to the madrigal; the declamatory recitative of the opera was the source of the 'second movement;' and the remaining portions of the sonata were founded on dance-rhythms. Its progress tended towards emancipation from originating influences, whereas the suite adhered closely to dance forms. To secure for each movement structural balance and diversity of material additional 'subjects' were introduced, and the several portions were divided into 'sections,' balanced and contrasted both as to melody and key; whilst, as to time, the alternation of quick and slow movements became a recognised principle. Corelli and other writers of his school wrote sonatas chiefly for the violin, the genius of Handel and Bach being also employed in the same field. The improvements effected in the construction of the harpsichord and clavichord at length obtained for them a due measure of attention from Domenico Scarlatti and C. P. Emanuel Bach, whose complete mastery of these instruments enabled them to write clavier-sonatas with the happiest effect. The subsequent efforts of Haydn and Mozart brought the form of the sonata to great perfection of elegance and symmetry, a result to which Clementi and Dussek also contributed. But the acme of development was reached by Beethoven, who infused into the somewhat mechanical forms of his predecessors the spirit of human emotion. Under him the different parts of the sonata, instead of being mere adjacent sections, became items of one complete organic whole. The progression of his thoughts constituted a work of art, a poem in sound, in which, while the idea was paramount, the form was more or less veiled, the perfection of the whole resulting from a true and just balance between the two. Weber and Schubert continued to employ the old model, but with them its rules and restraints gradually gave way before the growing importance of the idea. At a later period Schumann attempted a compromise by means of ingenious devices, and Brahms in two early pianoforte-sonatas had worked along similar lines; while notable composers of the present day are still trying to extend the limits of sonata-form in conformity with modern tendencies. See the article by Dr C. Hubert H. Parry in Grove's *Dictionary of Music.*

Sonderbund, a union of the Catholic cantons of Switzerland (q.v.), which led to civil war in 1845.

Sonderburg. See ALSEN.

Sondershausen, the chief town of the German principality of Schwarzburg-Sondershausen (q.v.), pleasantly situated on the Wipper, 34 miles by rail N. of Erfurt. It has a large castle. Pop. 6336.

Sondrio, an Italian town, capital of a province, on the Adda, 25 miles E. of Lake Como; pop. 3989.

Song, a short poem, adapted for singing, or set to music. A song generally turns on some single thought or feeling simply expressed in a number of stanzas or strophes (see LYRIC, BALLAD, POETRY, and the articles on the great song-writers). The music to which it is allied should serve to add force and clearness to its meaning with or without the assistance of an instrumental accompaniment. The vast stores of simple ballads, of which various nations in time became possessed, are known as 'folk-songs' (*volkslieder*), as being the unstudied outcome of their popular tastes, feelings, and aspirations. In the modern 'art-song' (*kunstlied*) the cultivated instincts of the musician are brought to bear upon the utterances of the poet. The range of this class of song is extremely wide, and includes examples resembling the folk-song in simplicity, as well as those of a more ambitious character, which for adequate interpretation often depend very largely on the accompaniment, the voice part sometimes consisting of little more than declamation of words whose meaning is further conveyed by instrumental devices. Between these two extremes every variety and combination of treatment is displayed, some songs being strophic in form, the same melody serving for each stanza, whilst others are 'composed throughout,' both melody and accompaniment changing in sympathy with the narrative and sentiments expressed by the words. The pinnacle of perfection in song-writing has been reached by German composers, and pre-eminently by Schubert, Schumann, Brahms, and Loewe. Among celebrated English composers of song music may be named Henry Lawes, who very early excelled in the art of setting words with due regard for accent and emphasis; Henry Purcell, the greatest among English song-writers; with Carey, Arne, and Boyce. To these must be added Dibdin, famous for his 'Tom Bowling;' Davy, whose memory is kept green by his 'Bay of Biscay;' John Braham, who wrote the 'Death of Nelson;' and Charles Horn, composer of 'Cherry Ripe.' Sir Henry Bishop also enjoyed a lengthened popularity. The growth of national taste in respect of song has not kept pace with its advance in other branches of music, many excellent writers belonging to the later part of the 19th century being as yet for the most part unappreciated, while publishers find a large sale for vapid compositions in the so-called 'drawing-room' style. Songs written for several voices are known as part-songs, glees, madrigals, &c. See CATCH, GLEE, MADRIGAL, ROUND; and the article 'Song' in Grove's *Dictionary of Music*. For the song of birds, see BIRD, Vol. II. p. 169; and for the Song of Songs, or Song of Solomon, see CANTICLES.

Songhay, or SONRHAI, a former kingdom of Africa, extended on both sides of the Niger below its great bend. In the 15th century the empire extended from Lake Tsad almost to the Atlantic, but early in the 17th century it was overthrown by the sultan of Morocco. The capital was Garo.

Song-ka, the chief river of Tong-king (q.v.).

Sonnblick, a hill 10,277 feet high amongst the Salzburg Mountains, on whose summit is a meteorological observatory, with a shelter built in 1886 by the Austrian and German Alpine Clubs.

Sonnet (Ital. *sonetto*, dim. of *suono*; Fr. *sonnet*). In poetic art the sonnet—a stanza mostly iambic in movement, properly decasyllabic or hendecasyllabic in metre, always in fourteen lines arranged properly according to some law that is recognised at once as having universal acceptance—belongs entirely to the rhymed poetry of the modern world. Sonnets are divided into regular and irregular. All regular sonnets are divisible into: (1) The sonnet of simple stanza in which the staves follow each other in three quatrains of alternate rhymes clinched at last by a couplet. This form is for obvious reasons called the Shakespearian sonnet. (2) The sonnet of compound stanza divided generally, but not always, both as regards sense-rhythm and metre-rhythm, into two parts—an octave consisting of eight lines (the first line of which rhymes with the fourth, the fifth, and the eighth lines, the second line with the third, the sixth, and the seventh), and a sestet consisting of six lines running on two or else three rhymes in an arrangement which, though free from prescription, must always act as a response by way of either ebb or flow to the metrical billow embodied in the octave. This form is for equally obvious reasons called Petrarchan. Within the space at our command it is impossible even to glance at the history of the sonnet here, save as it now and then discloses itself in our remarks upon the general principles governing the sonnet's matter and its form.

Though poetic art has many functions and many methods, the two following among its functions seem specially to concern us in treating of the sonnet: The function of giving spontaneous voice to the emotions and passions of the poet's soul; and the function of poetising didactic matter and bringing it into poetic art. With regard to the first of these functions, although the sonnet is a good medium for expressing passion and emotion, it cannot be said to take precedence in this respect of other and less inherently monumental forms. The ode of Sappho, the bird-like song of Catullus, and the free-moving rhymed lyric of modern times are probably better adapted to give expression to simple passion at white heat—while on the other hand they are certainly better adapted to give voice to that less intense form of passion which can pause to deck itself with the flowers of a beautiful fancy—than is the sonnet—even the sonnet of simple stanza of Shakespeare and Drayton. With regard, however, to the second of the above-mentioned functions of the poet—that of poetising didactic matter—a function which of course can only be exercised by passing the didactic matter through a laboratory as creative and as recreative as nature's own, the laboratory of a true poet's imagination, the pure lyric must of course yield to the sonnet. Indeed, it is an open question whether since the Romantic revival the sonnet has not been gradually taking precedence of most other forms as an embodiment of poetised didactics. And should this on inquiry be found to be the case, the importance of this form will be made manifest. For as the mind of man widens in mere knowledge and intelligence fresh prose material is being furnished for the poetic laboratory every day. And the question, What is the poetic form best suited to embody and secure this ever-increasing and ever-varying wealth?—a question which has to be answered by each literature, and indeed by each period of each literature, for itself—goes to the root of poetic criticism. Of course, before didactic matter can become anything more than versified prose, it has to be excarnated from the prose tissue in which all such matter takes birth, and then incarnated anew in the spiritualised tissue of which the poetic body is and must always be composed. Hence it is not enough for the poet to use the sieve, 'as Dante would say,' in selecting 'noble words.' The best prose writers from Plato downwards have been in the habit of doing this. When Waller said:

> Things of deep sense we may in prose unfold,
> But they move more in lofty numbers told,

he meant by 'lofty numbers' those semi-poetic 'numbers' of the English couplet in which poetised didactics were in his time embodied—as in the time of Shakespeare such poetised secretions of the mere *intellectus cogitabundus* were put into the mouths of dramatic characters after the approved old fashion of the classical dramatists.

Since the Romantic revival, however, poetic art has undergone an entire change. Acted drama cannot now receive poetised didactics, which would in these days slacken the movement and disturb the illusion required, while as to the kind of epigram-in-solution or half-poetised quintessential prose which is embodied in the 18th-century couplet the criticism of the Romantic revival is apt to consider this not so much as poetry as an intermediate form—and an extremely rich and precious one—between poetry and prose. Epigrammatic matter must, to exist at all, be knowing, and as knowingness and romanticism are mutually destructive, it is evident that some form other than the couplet, which is so associated with epigram, must in our time be used for the poetising of didactic matter of the unworldly and lofty kind. And the sonnet of octave and sestet is a form less epigrammatic than any other—a form moreover which can never, as certain other stanzaic forms can do, embody mere quintessential prose without proclaiming its poverty, but must always be poetic in its very texture—a form indeed which will not bear one line that is not either in essence or in method poetic or else 'rhetorical' in Dante's sense when he defined poetry to be 'a rhetorical composition set to music.' So absolutely poetic a form is this that if it should happen that the diction will not on account of the subject bear elevation, it has to be at once poetised by one of those skilful disturbances of the prose order of the words of which Wordsworth was so great a master.

The fact of the word sonnet being connected with *suonare*, to play upon an instrument, shows that a knowledge of music, though perhaps not essential, is of great value to a sonnet-writer. Indeed, owing to the consonantal character of our language a knowledge of music is really of more importance to the English than to the Italian sonnet-writer. Although the 'singing words' essential to a good song for music need not perhaps be greatly sought in the sonnet (save in the special and somewhat rare form mentioned further on), still vowel-composition and that attention to sibilants which Pindar is constantly showing in his odes—that attention which Dionysius of Halicarnassus extolled—and also the softening of consonantal feet by liquids are extremely important in the sonnet even although it is no longer written to be set to music. After much practice in the art of rhymed poetry—when every feasible rhyme leaps into the brain of the poet the moment that a line-ending has suggested itself to his mind—this attention to structural demands becomes instinctive, and is exercised in that half unconscious and rapid evolution of the mental processes which the witty conversationist shows in repartee, and which the pianist exhibits when touching the keyboard—supposing of course that the poet is a born rhymer. It is, however, a curious and interesting fact that ever since the time of Piers Plowman (when alliterative measures gave way to rhymed measures) English poets have been clearly divisible into two classes—those to whom rhyme is an aid and those to whom rhyme is more or less a check. And still more curious and interesting is it, that while three of the greatest poets, Shakespeare, Marlowe, and Milton, belong to the one class, Coleridge (who by endowment perhaps stands next to them) belongs to the other. This is why some of the strongest English poets have not been successful in the sonnet, where the rhyme-demands are very great. For some reason or another the rhythmic impulse within them has not been stimulated but crippled and tortured by the spur of rhyme.

With regard to prescription in the number of the lines and the arrangement of the rhymes of the sonnet, metrical art offers the reader two opposite kinds of pleasure; the pleasure derived from a sense of prescribed form, as in the sonnet, the ballade, the rispetto, the stornello, &c., and the pleasure derived from a sense of freedom from prescribed form as afforded by those pure lyrics, in which the form is, or at least should be, governed by the emotion. Now every poetical composition should show at once which of these kinds of pleasure is being offered to the reader and should also satisfy the expectation raised, for he will experience a sense of disappointment on being proffered one kind of poetic pleasure when he has been led, by the stanzaic arrangement or otherwise, to expect another. Nevertheless a certain few of our great sonnets are irregular, for a great poet can do anything.

With reference to regular sonnets it is self-evident, as regards the sonnet of compound stanza, that there are four different forms into which may fall a metrical structure consisting of an octave of a prescriptive arrangement of rhymes and a sestet consisting of another set of rhymes that are free in arrangement from prescription. And some years ago the present writer exemplified these in 'four sonnets on the sonnet,' one only of which, under the name of 'The Sonnet's Voice,' originally printed in the *Athenæum*, was widely circulated in sonnet-anthologies. These varieties of the sonnet of octave and sestet are: (1) The sonnet in which the stronger portion both in rhythm and in substance is embodied in the sestet. (2) The sonnet in which the stronger portion both in rhythm and in substance is embodied in the octave. (3) The sonnet in which the sestet is not separated from the octave, but seems to be merely a portion of the octave's movement rising to a close more or less climacteric. (4) The sonnet in which the sestet seems to be added to the octave's movement, added after its apparent termination in a kind of tailpiece, answering to what in music we call the 'coda.'

With regard to the second of these varieties—the one exemplified in 'The Sonnet's Voice'—perhaps the ideal form has the octave in double rhymes and the sestet in single rhymes. But it has to be remembered by the poet that between the effect of Italian rhymes and the effect of English double rhymes there is a great difference. Save in the hands of a sonnet-writer of great practice in the art of vowel-composition, in the art of using singing words, and in the art of softening our consonantal language, by the proper use of liquids and subtle and concealed alliterations, the English rhyme-beat in the double-rhyme octave of this variety is apt to become too heavy for the single-rhyme rhyme-beat in the sestet. By attention to these requirements, however, the rhyme-beat may be so lightened that this variety may become the most brilliant of all.

With regard to the sonnet of simple stanza, it has two special glories: it was the form adopted by Shakespeare, and in it is written Drayton's famous love-sonnet. Hartley Coleridge wrote some fine sonnets in this form; so did Keats: but on the whole it has been neglected in recent times. A renewed attention has, however, been lately given to it by critics of the sonnet both in England and America owing to Dr Gordon Hake's book of nature poems, *The New Day*, where the Shakespearian form of sonnet is used. Here, by a free use of double rhymes the poet gives a lyrical movement to his verse, which, though an occasional feature of Shakespeare's sonnets, is not a characteristic one.

Sonmiáni, a miserable town and port of 4000 inhabitants on the coast of Beluchistan, 52 miles NW. of Kurrachee.

Sonora, a frontier state in the north-west of Mexico, on the Gulf of California. It is the second largest in the republic. Area, 77,526 sq. m.; pop. (1888) 105,391. The coast is flat and sandy, the interior filled with wooded mountains and fertile valleys. Malaria is mostly confined to one part of the coast. Here the climate is hot, but in the mountains there is frost for five months in the year. The chief rivers are the Sonora, Yaqui, and Mayo. The principal wealth of the state is in its minerals, especially gold, silver, mercury, and iron. Agriculture, wine-growing, and cattle-rearing are also successful, and cottons, hats, shoes, and soap are manufactured. Capital, Hermosillo; chief port, Guaymas.

Sonsonate, a town of Salvador, on the Rio Grande, 15 miles by rail N. of Acajutla. It was founded by Alvarado in 1524. Pop. 8000.

Sontag, HENRIETTA, COUNTESS ROSSI, a German singer, was born at Coblenz on 3d January 1806, and was educated by her parents to their own profession of the stage. She learned singing at Prague, and made her début there when only fifteen. After a brilliant operatic career at Vienna, Berlin, and Paris, she married Count Rossi in 1828, and shortly afterwards left the stage. Compelled by pecuniary difficulties to reappear in 1849, she met with renewed success both in Europe and America, but died in Mexico on 17th June 1854.

Sonthals. See SANTALS.

Soochoo, or SUCHAU, previous to the Taiping rebellion one of the largest cities in China, is situated on the Imperial Canal, 50 miles WNW. of Shanghai, in the province of Kiang-su. It stands on numerous islands separated by canals, and on this account has been compared to Venice. The city walls have a circuit of 10 miles. Soochoo has for generations been a noted centre of the silk manufacture and of the printing of cheap Chinese classics. It was captured by the Taipings, but recovered by 'Chinese' Gordon in 1863, on which occasion the city with its many handsome buildings was almost wholly destroyed. Pop. 500,000.

Sooloo Islands. See SULU ISLANDS.

Soot. The soot both of wood and of coal is serviceable as Manure (q.v.) on account of the sulphate of ammonia it contains, especially for young cereals, for grasses, and for carrots. See SMOKE.

Sophia. See SOFIA.

Sophia, Electress of Hanover, born on 13th October 1630, was the youngest of the thirteen children of Elizabeth (q.v.), queen of Bohemia. In 1658 she married Ernest Augustus, Duke of Brunswick-Luneburg, and afterwards Elector of Hanover, and by him she was the mother of George I. She died 8th June 1714. See her *Memoirs* (*Eng. trans.* by H. Forester, 1888). For Sophia Dorothea, the wife of George I., see KÖNIGSMARK.

Sophia, ST (Greek *Hagia Sophia*, 'Holy Wisdom'—i.e. the eternal wisdom of God or the Logos, and not a human saint), to whom Greek churches were often dedicated; especially the great church of Constantinople (q.v.), erected by Justinian in 538-568 A.D. Its dimensions and a sectional plan are given at BYZANTINE ARCHITECTURE.

Sophists. The Greek word *sophistēs* (from *sophos* = 'skilled,' 'wise') meant originally any one of acknowledged or professed skill; thus, the term was applied to the seven sages (whether philosophers, like Thales, or statesmen, like Solon), to poets, musicians, &c. In the 5th and 4th centuries B.C. it came to be applied specially to those who made a profession of teaching all or any of the higher branches of learning. The great intellectual awakening of Athens after the Persian war, and the growth of democracy in Sicily and elsewhere, as well as at Athens, which gave skill in public speaking a new importance, led to the demand for an education which should go beyond the old training in 'gymnastic' and 'music' (i.e. reading, writing, singing, and reciting from the poets). To meet this demand there arose a class of professional teachers, wandering scholars, who undertook to provide what we should call 'higher education.' This new movement presents certain resemblances to the rise of the universities in the 13th century, to the popularising of learning and science in the 18th and 19th centuries, to the 'University Extension' movement of to-day. Some of these 'Sophists' were more specially teachers of rhetoric—i.e. they gave particular attention to the *form* of public speaking, and as such they are the beginners of Greek prose style. Originally *artistic* expression takes the *form* of verse. The poet is the 'maker,' the artist in language: prose is simply 'ordinary speech.' But from the time of the rhetoricians, such as Gorgias (q.v.) of Leontini, prose also becomes an art. The first effect of the deliberate pursuit of artistic form in prose was to produce a pedantic and artificial style. (We can trace the evil influence of Gorgias in the 'speeches' in Thucydides.) But this attention to language was the preparatory training for the simple beauty of the best Attic prose. Other Sophists gave more attention to the *matter* of public speech—the questions of right and wrong which come before law-courts and political assemblies—and in this way they were the beginners of moral and political philosophy. The earlier Greek philosophers, with the partial exception of the Pythagoreans, had hardly treated of human matters: they had been ontologists and cosmologists. Protagoras (q.v.) of Abdera and Prodicus of Ceos may be taken as famous and favourable examples of the professors of 'virtue.' It must be remembered that the teacher of conduct and the moral philosopher were not distinguished even by Plato and Aristotle. Other Sophists, like Hippias of Elis, professed to teach universal knowledge—what we call 'general culture.' Others again, like Euthydemus and Dionysiodorus (who appear in Plato's dialogue named after the first of them), devoted themselves specially to the art of disputation, and thus prepared the way for the science of logic.

The ambitious youth of Athens flocked to a fashionable Sophist from intellectual interest in the new learning and in order to acquire an education which would fit them to obtain success in the law-courts and in the popular assembly, or to acquit themselves with distinction in a discussion on any subject whatever. The various Sophists naturally differed much from each other in ability, in character, and in the degree of seriousness with which they regarded their function as teachers; and some may very well have deserved the censure expressed in Aristotle's definition of the Sophist as 'a man who makes money by sham wisdom' (in *Soph. Elench.* i). In the eyes of old-fashioned persons the whole class was regarded with suspicion: the skill of the clever orator or disputant seemed to have something immoral about it, because it might enable the worse cause to appear the better. And to discuss the nature of right and wrong, or to theorise about the foundations of society, was then, as in other ages, regarded as dangerous. In the eyes of such persons Socrates and Plato were 'Sophists' just as much as the rest, although

Socrates and Plato, conscious of their own intellectual honesty and earnestness, and not teaching for 'pay,' disowned the title. When the various branches of the new learning came to be differentiated, we find the rhetorician Isocrates (q.v.), to whom the term would certainly be applied by the average Athenian and by Plato, applying the term to Plato, but not to himself. Again, whereas Plato applies it to Protagoras, Gorgias, Hippias, &c., we find that Aristotle in a passage (*Eth. Nic.* ix. 1) where he speaks disparagingly of the Sophists contrasts Protagoras with them. The word had come to acquire an evil connotation, such as survives in our use of the term 'sophistry.' But it is quite a delusion, as was conclusively shown by Grote (*History of Greece*, pt. ii. chap. 67), to suppose that the Sophists were a *sect* of philosophers, with pernicious principles, who systematically undermined the morality of the Hellenic world. They were not a sect, but a profession: and on the whole they were neither better nor worse than their age. Like the journalist or litterateur of our own time, they succeeded by supplying what the public wanted. The Platonic Socrates, their adversary, himself says, 'Our youth are corrupted, not by the individual Sophists, but by the public, which is the great Sophist, against whose influence any private teacher wages an unequal contest' (*Republic*, vi. 492).

There is no common 'Sophistic' doctrine. Different Sophists were influenced by different schools of philosophy. They were the popularisers of older doctrines. Thus, Protagoras was influenced by Heraclitus (q.v.), whose doctrine of universal flux gives a basis for Protagoras' assertion of the absolute relativity of knowledge ('man is the measure of all things;' nothing is true but the sensation of the moment). The alleged influence of his fellow-townsman, Democritus (q.v.), seems less likely; for Democritus was about twenty years younger. Still the Atomist resolution of all things into mere *arrangements* of the only *real* existences (the atoms and the void) very likely helped to supply a basis for the distinction between 'convention' and 'nature,' which was much used by some Sophists and became a commonplace of the period. Gorgias is said to have been a disciple of Empedocles (q.v.), and was certainly influenced by the Eleatics (q.v.). His paradoxical treatise on 'Nature or the non-existent' is clearly a sceptical working out of the Eleatic principle of the unreality of the manifold. We have no sufficient knowledge to justify the attempts made by some German scholars to classify the Sophists according to different philosophical schools; and it is, moreover, unlikely that *popular* philosophers should admit of any very precise affiliation. We can only group them in a very rough way, such as has been attempted above. Some historians of philosophy (e.g. Zeller and Ueberweg) lay stress on the distinction between the earlier and later Sophists, considering the 'later Sophists' (such as Polus of Agrigentum, a pupil of Gorgias, Thrasymachus of Chalcedon, Euthydemus, &c.) to represent a distinct degeneracy in the class. This, however, seems doubtful, except in the sense that, as time went on, 'rhetoricians' and 'philosophers' came to be more clearly differentiated from among the mass of the profession; and the *name* Sophist degenerated as we have seen. Professor Sidgwick has argued that the 'Eristic' or disputatious Sophists are really a degenerate offshoot of the Socratic school; but against this hypothesis there are many objections.

While Grote is perfectly correct in holding that the Sophists are not a sect and have no common doctrine, he errs in ignoring the fact that they represent a common tendency, the new spirit of the age. The awakening of reflection on political and social institutions, on morals and religion, and the wider diffusion of enlightenment produced in Hellas the same spirit of 'freethinking,' individualism, and sceptical criticism which we find among the 'Humanists' of the Renaissance, and still more among the English 'Deists' and French 'Encyclopædists' of the 18th century. Of this intellectual movement the Sophists were at once the outcome and the leaders. The differences between the Sophists might be paralleled by the differences between Voltaire, Diderot, Rousseau, &c., and yet all these writers share a common tendency. The very opinions maintained by certain Sophists reappear in more fully developed forms among English and French writers of the 17th and 18th centuries. Thus, Thrasymachus, in Plato's *Republic*, bases right simply on the command of the stronger, by which he means the sovereign power in the state—the theory of Hobbes, developed afterwards in its legal aspects by Bentham and Austin. From the second book of Plato's *Republic* it appears that the Social Contract theory had already been propounded, almost certainly by some Sophist. Aristotle (*Politics*, iii. 9) quotes Lycophron the Sophist as holding that government was only concerned with the protection of individual rights. Alcidamas, the rhetorician, maintained that 'God made all men free; Nature has made none a slave.' This and similar sentiments, which we may call 'Sophistic,' in the sense that they belong to the new Rationalism, are to be found frequently expressed in the extant plays and fragments of Euripides. Even Herodotus, though his style is unaffected by the rhetorical schools, has also imbibed a certain tolerant scepticism, which appears in his treatment of the diversity of customs and religious beliefs; and the debate about the best form of government (iii. 80–82), which he unhistorically puts into the mouth of Persians, is probably due to a 'Sophistic' source, and may indeed be called the earliest piece of Greek political philosophy that has come down to us. Much of the teaching of the Sophists was undoubtedly destructive of the old fabric of Greek belief and of Greek society, which rested on the narrow basis of an exclusive citizen caste with a substructure of slavery. The modern student will not necessarily think the worse of the Sophists on that account; though the majority of them were probably by no means conscious of the significance of the critical weapons they handled. By raising problems in almost every department of thought, for which they could find no satisfactory answers, they prepared the way for the great period of Athenian philosophy (see SOCRATES). In later times the term 'Sophist' came into reputation again; and some of the Greek professors of rhetoric under the Roman empire were described as Sophists on their tombs.

Besides the histories of Greek philosophy referred to under PLATO, and Grote's chapter mentioned above, may be named two articles by Professor Henry Sidgwick, defending Grote's view, in the *Journal of Philology*, vols. iv. and v. In A. W. Benn's *Greek Philosophers* (2 vols. Lond. 1883) chap. ii. deals with the Sophists, and is entitled 'The Greek Humanists.' The significance of the Sophists in the development of Greek thought was first put in a true light by Hegel in his *History of Philosophy*.

Sophocles, the Athenian tragic poet, was born in 496 B.C., and died in 405 at the age of ninety-one. His father's name was Sophillus, and his native district was Colonus, a suburban quarter on the banks of the Cephissus, much frequented by the knights and wealthy citizens of Athens. He partook in full measure of the highest education of his time, and was especially distinguished in music, which he learned from Lamprocles. At sixteen he was chosen to lead the chorus of youths who celebrated the naval victory of Salamis (480). At the age of twenty-eight he came to the front by entering into competition with Æschylus, his elder by thirty years, whose pre-eminence as a tragic poet had long been undisputed. The judges on this occasion, according to an oft-repeated tradition, were Cimon and his fellow-generals, just returned from Scyros. The younger poet was preferred; and his triumph had a decisive influence on the future of the tragic art. For not only are the mature works of Sophocles and those of Euripides, his younger brother in poetry, the fulfilment of the promise then given, but the Orestean trilogy of Æschylus, in which Greek tragedy attained its highest limit, was brought out ten years after this, and bears unmistakable proofs of the impression which the art of Sophocles had made upon his elder and greater rival. Sophocles never forsook Athens as both Æschylus and Euripides did, but he was repeatedly employed on embassies to other Grecian states, and in the Samian war of 440 he was appointed general in a joint command with Pericles. This choice is said to have been due to the success of the *Antigone*, one of the earliest of the poet's seven extant plays, as the *Œdipus Coloneus* and *Philoctetes* are certainly the latest. The probable order is *Ajax*, *Antigone*, *Electra*, *Œdipus Tyrannus*, *Trachiniæ*, *Œdipus Coloneus*, *Philoctetes*. Less than a tithe of the work of Sophocles remains to us; but of the seven plays each one has superlative excellences, and stands prominently forth amongst the master-works of the human spirit. The characteristics of Sophocles are a dramatic structure all but faultless, the combination of wonderful subtlety with intense fire, and of a noble ideal with truth and naturalness. His subjects were necessarily drawn from Hellenic legend. His motives in selecting them were mainly artistic, but to some extent also religious or patriotic. In his treatment of them he never loses sight of the main principles of tragic art. His method turns largely on pathetic contrasts (1) of situation, (2) of character.

(1) The change of fortune which forms the crisis of each play is often rendered more impressive through the profound unconsciousness, at the beginning of the action, of the persons who are to be affected by it. The case of Œdipus is the capital illustration of this remark; but it applies also to Creon in the *Antigone*, to Electra, Deianira, Philoctetes, and to the chorus in the *Ajax* and *Œdipus Coloneus*. Sometimes the chief agent, Antigone for example, is fully conscious of the real position of things, but in every case appearance and reality are strongly opposed.

(2) The persons in Sophocles are most skilfully adapted to the main situation and action of each play. The addition of a third actor to the two that had formerly sufficed enabled the poet not only to contrast opposed natures, such as Antigone and Creon, but to introduce finer shades of difference, as between Antigone and Ismene, or Agamemnon and Odysseus. Perhaps the most notable instance of such delicate portraiture occurs in the *Philoctetes*, where Neoptolemus, the ingenuous youth, is contrasted equally with the politic Odysseus and with the hero of the play, in whom a generous nature has been embittered by ill-treatment and solitude.

The *Ajax* may be described as the tragedy of wounded honour. Ajax and Odysseus had recovered the dead body of Achilles, whose armour, the miraculous work of Hephæstus, was then awarded not to Ajax, the most valiant of the surviving Greeks, but to Odysseus, the wisest. Half-maddened by repulse, Ajax would have assassinated the generals; but, to defend Odysseus, Athena made the Telamonian warrior wholly mad, and turned his violence against the flocks and herds belonging to the army. On awaking from his delirium, finding his honour lost, he resolves on death. Agamemnon would have refused him burial; but Teucer vindicates him, and Odysseus, with becoming magnanimity, ends the strife. Tecmessa, the captive bride, who in her helplessness defies the Argives and protects the hero's child, is one of those female characters which Sophocles portrays with so much skill.

In the *Antigone* the claims of piety and natural affection are seemingly overborne by the exaggerated assertion of state-authority in the person of the ruler, but in the end it is the ruler who succumbs. The virgin martyr is vindicated.

In the *Electra*, in place of the fiery Theban maiden, the poet represents the faithful endurance of the Argive princess, who in the *Oresteia* of Æschylus had played a subordinate part, but here rises to the height of female heroism.

The *Œdipus Tyrannus* was regarded by Aristotle as the *chef d'œuvre* of tragedy, and nowhere else is there to be found an equal combination of constructive ingenuity with tragic power. The hero is represented as the most loyal and affectionate, but also the most passionate, and, partly for that reason, the most unfortunate of men. Doomed to misery in his very birth, he appears to himself and others at the opening of the play to be at the height of prosperity. A stranger, he has earned the affection of Thebes, and lightly he undertakes the quest imposed by the god. In the sequel he discovers that he is the forbidden child of the king—whom he has slain—and of the queen—whom he has married! The poignancy and pathetic interest which Sophocles extracts from this unnatural story is a triumph of poetic skill. In the construction of the piece the employment of the Theban slave, who had been charged with the exposure of the child, and had also witnessed the death of Laïus, is especially noteworthy.

The subject of the *Trachiniæ* is the death of Heracles, but the fatal act of Deianira in sending the poisoned robe (which she believes to be a charm for recovering the affection of her lord) forms the central motive. She is one of the most charming of poetic creations, 'the rival of Imogen in purity, of Katharine of Aragon in her great patience, and of both in wifely spirit.'

There was an interval probably of at least ten years between the *Œdipus Tyrannus* and the composition of the *Œdipus at Colonus*, which indeed is said to have been exhibited for the first time only after the death of the poet. Meanwhile the genius of Sophocles had mellowed, and the spirit of the age had undergone some change. What in Euripides becomes a sort of moral casuistry appears in Sophocles at this period as a serenely contemplative mood immersed in ethical reflection. He has adorned the legend of his birthplace with undying beauty. But the moral dignity of the *Coloneus* is different in kind from the tragic fire of the *Tyrannus*.

The *Philoctetes* was produced in 409. It is a marvellous work for one in his eighty-seventh year to have composed. The characters are powerfully distinguished, and their mutual interaction is a new thing in dramatic poetry. Philoctetes, like the Œdipus of the *Coloneus*, is rejected by man, but accepted by the gods. Ill-usage and solitary musing have fixed in him the resolution never to return. The policy of Odysseus and the affectionate pleading of Neoptolemus are alike in vain, until the hard knot is loosed by the apparition of Heracles (in Euripidean style), who had been the hero's master and patron in the world of men. The interest of the action, which would else be stationary for so long, is sustained by the conflict in the soul of Neoptolemus, in whom ambition and public duty are struggling with pity for Philoctetes, and with the love of truth which the young chief inherits from his father Achilles. The victory of his better nature forms the culminating point in the action of the play.

Of other subjects known to have been treated by Sophocles those most suggestive of tragic interest are Alcmæon, Atreus, Danaë, Hermione, Thamyras, Thyestes in Sicyon, Iphigenia, Clytemnestra, Creusa, Laocoön, Meleager, Niobe, Œnomaüs, Peleus, Telephus, Tereus, Troilus, Phædra, Phineus. The remaining fragments of these and other plays are on the whole disappointing. Sophocles even less than other poets can be fairly represented by isolated passages.

Amidst much variety, the dramatic work of Sophocles presents some constant features. Each play has a preliminary scene in which the main situation is set forth. This is followed by the entrance of the chorus, consisting of persons who stand in some well-considered relation to the chief agent. Then fresh complications supervene, and the action rises in steady climax to the turning-point. The reverse of fortune is generally announced by a messenger, after whose speech the *commos* or interchange of lamentation between the stage and orchestra naturally comes in. Between the scenes choice odes or *stasima* are interposed. But the lyric numbers are not confined to these. At suitable moments the chorus, and sometimes the actors themselves, break out into song, which on the part of the chorus is sometimes accompanied with dancing of a more or less animated description. This takes effect particularly in the *hyporchema*, or dancing-ode, which Sophocles is fond of employing at some conjuncture where the *dramatis personæ* have been deceived for the moment into a false and short-lived joy. This relieves the monotony of gloom while ultimately rather heightening tragic effect, by emphasising the contrast above noticed between appearance and reality.

Sophocles has not impressed the world with superhuman grandeur, as Æschylus has done. Nor has he charmed mankind by the witchery of style in particular scenes and descriptive passages, as appears to have been the case with Euripides. But to some of the greatest critics—e.g. Lessing—his merits as a dramatic artist have appeared to be supreme. The purely human note in tragedy is dominant for the first time in him. Matthew Arnold in an early sonnet described him well:

> Be his
> My special thanks, whose even-balanced soul,
> From first youth tested up to extreme old age,
> Business could not make dull, nor passion wild;
> Who saw life steadily and saw it whole;
> The mellow glory of the Attic stage,
> Singer of sweet Colonus and its child.

If not quite holding the first rank with Homer, Æschylus, Dante, and Shakespeare, Sophocles is at least one of the immortals.

The *editio princeps* was printed at Venice in 1502. In the long list of editors of the whole or part of the seven the most important names are Brunck, Gottfried Herrmann, Wunder, Dindorf, Schneidewin, Hauck, Bergk, Lobeck (*Ajax*), Böckh, Meineke, Elmsley, Buttmann, Linwood, Kennedy, Wolff, O. Jahn. The chief modern English annotated editions are those of F. H. M. Blaydes and F. A. Paley (2 vols. 1859-80), Prof. Lewis Campbell (2 vols. 1873-81), and Prof. Jebb (Cambridge Press, vols. i.-v., 1884-92)—a masterly edition, in which Sophocles is treated with admirable thoroughness and clearness. Of English translations may be named those of Francklin, Potter, Dean Plumptre, Sir G. Young, R. Whitelaw (1883), and Prof. Lewis Campbell (complete, 1883) in verse; and those given in Prof. Jebb's edition, in admirable prose.

There is an excellent *Lexicon Sophocleum* by F. Ellendt (2d ed. by H. Genthe, Berlin, 1867-72), supplemented by an 'Index Commentationum' (1874). See Hense, *Studien zu Sophocles* (1880); Patin, *Études sur les Tragiques Grecs* (vol. ii., new ed. 1877); Prof. Lewis Campbell, *Sophocles* in Green's 'Classical Writers' (1879), and *A Guide to Greek Tragedy* (1891); also Schlegel's *Lectures*, and Bishop Thirlwall's *Remains* for a famous essay on the Irony of Sophocles.

Soprano (Ital.), the highest species of voice. Its average range extends from C below the treble stave to A above it; but the greatest variety in compass and quality is found. The highest compass on record is that of Agujari, which on the testimony of Mozart reached to C in *altissimo* (three octaves). Music for this voice is now written with the G or treble clef; but in German full scores the old soprano clef, C on the first line, is still used. The *mezzo-soprano* has a somewhat lower range, usually from A beneath the treble stave to F on the fifth line. See VOICE.

Sora, a city of Italy, on the Garigliano, 55 miles E. by S. of Rome. Pop. 5411.

Sorata, a volcanic peak of the Bolivian Andes, to the east of Lake Titicaca, rising to 21,470 feet above the sea.

Sorau, a town of Prussia, 60 miles by rail SSE. of Frankfort-on-the-Oder, has three castles (one dating from 1207), some good churches, and manufactures of cloth, linen, cigars, &c. Pop. 13,665.

Sorb. See SERVICE.

Sorbonne, the earliest, as it was by far the most famous, of all the colleges of the mediæval university of Paris. The system of colleges, of which the Sorbonne was the first example, dates only from the later part of the 13th century, more than a hundred years after the beginnings of the university itself. The system sprang out of the necessity for the adequate accommodation of the vast numbers of students who flocked to Paris from all the countries of Europe. Previous to the erection of colleges the students had mainly to content themselves with such lodging as they could find, and experience had shown that they had suffered both in their purse and their morals from this system.

It was the happy inspiration of Robert of Sorbon, in the diocese of Rheims, to conceive and carry out the idea of combining a place of residence and a place of study. With the consent of St Louis, to whom he acted as chaplain, Robert founded the college of the Sorbonne in 1253, though it was not formally opened till 1256. By a bull of Clement IV. (1268) the new institution received the indispensable sanction of the pope as the head of all the mediæval universities. At the head of the college was the *provisor*, who was chosen by the whole university, though its business was mainly in the hands of the *prior*, elected every year from the members of the college itself. The members were divided into two classes, *Hospites* and *Socii*. The Hospites received the full benefit of the educational provisions of the college, but they had no part in its administration. On the attainment of the doctorate in theology at the age of thirty-five their residence came to an end. The Socii, who were restricted to the number of thirty-six, had the entire management of the college in their hands, and all, whatever their age or academic rank, were on a footing of absolute equality. The life of the college was according to the strictest monastic rule, and its inmates with proud humility styled themselves 'the poor masters of the Sorbonne.'

The Sorbonne was exclusively devoted to the study of theology, and no student could enter it till he had taken the diploma of Bachelor of Arts, and had sustained a thesis, known as the *Sorbonica* or *Robertina*, before all the members of the college. The discipline through which he had then to pass was the severest in all the Paris colleges. It was above all by the system of disputation that his progress was stimulated and his proficiency tested. By its rigorous methods of conducting these disputations the Sorbonne gained the reputation of being the first theological school in Europe; and its opinion on disputed points of doctrine was universally accepted as the weightiest that could be obtained. In affiliation with his larger college Robert of Sorbon in 1271 also founded a smaller college—that of Calvi, or the Little Sorbonne—where students were prepared in subjects preliminary to their study of theology. It was the distinctive feature of the Sorbonne, however, and one which greatly helped to win for it its predominance in the university, that its members were drawn from every country in Europe, and not confined to a particular 'nation.'

The history of the Sorbonne is a signal instance of a great institution admirably fulfilling its original intention, but incapable of making a new departure when such a departure was necessary for its continued vitality and efficiency. Till the close of the 15th century, when the scholastic theology was fast losing its hold on all the best minds, the Sorbonne filled a place of the first importance in the intellectual life of Europe. Throughout the middle ages the theological faculty of Paris was the main support on which the highest teaching had rested, claiming for itself the right, denied to the pope himself, of sovereign decree on the truth or falsity of all religious doctrine. But the Sorbonne virtually constituted the theological faculty, and in common speech was identified with it. Its voice therefore carried an authority that influenced the councils of the nation. Through its efforts France was saved from Peter's Pence and the Inquisition; and it was due to its encouragement that printing was introduced into Paris immediately subsequent to its invention.

From the beginning of the 16th century, when the new studies of the Revival of Learning found their way into France, the Sorbonne gradually ceased to represent the best thought of the country. To all reform alike in studies and religion it offered the most dogged resistance, and it was largely due to its action that Paris lost its place as the first school in Europe. Among the men of the new order the 'Sorbonnian bog' became a byword for bigotry and obscurantism. In the succeeding centuries the Sorbonne followed the same retrograde policy. In 1621 it actually obtained an edict, mainly directed against Descartes, forbidding all teaching that ran counter to accepted authorities. On the occasion of the erection of new buildings by Richelieu (1627), who was provisor of the college, a satirical Latin couplet declared that so long as its original home was in decay the Sorbonne was unassailable, but now that that home was renewed it would certainly go to ruin. The butt of the wits of successive generations, Boileau and Voltaire among the rest, the Sorbonne clung to its original traditions till at the Revolution (1792) its property was confiscated to other objects.

When in 1808 Napoleon reorganised the university of France, the Sorbonne was revived and became the seat of the *Académie* of Paris (see UNIVERSITY) and of the three faculties of theology, science, and literature. In 1884–89 a new set of buildings was erected at a cost of £880,000, to take the place of the college erected by Richelieu; the largest theatre can seat 3000. By a curious fatality the Sorbonne is still associated in France with undue respect for tradition in matters of education.

See the various histories of the university of Paris by Du Boulay, Crevier, and Denifle; also Duvernat, *Histoire de la Sorbonne* (2 vols. Paris, 1790), and Franklin, *La Sorbonne* (Paris, 1875).

Sorcery. See MAGIC, WITCHCRAFT.

Sordello. See BROWNING (ROBERT).

Soricidæ, a family of Mammalia, to which the Shrew (q.v.) belongs.

Sorel, a town of Quebec, seat of Richelieu county, on the St Lawrence, at the mouth of the Richelieu River, 45 miles (by rail 78) NE. of Montreal. It manufactures machinery, leather, and bricks, and was formerly the summer residence of the governors-general. Pop. 5791.

Sorel, AGNES, the mistress of the worthless dastard Charles VII. of France, was born in 1409 in the village of Fromenteau in Touraine, and came to court in 1431 in the train of the Duchess of Anjou. Her influence was beneficial as long as she lived, but she died suddenly in 1450.

Soresina, a town of Northern Italy, 16 miles by rail NW. of Cremona, with 6765 inhabitants.

Sore Throat. See THROAT.

Sorghum. See DURRA.

Sorrel (*Rumex*), a genus of plants of the natural order Polygoneæ, very closely allied to Polygonum (q.v.) and Fagopyrum (see BUCKWHEAT), but having the perianth divided into six segments, the three inner of which enlarge and cover the *achenium*. The genus is very naturally divided into two sections, the first of which is already noticed in the article DOCK. The name Sorrel belongs only to the second, characterised by diœcious flowers and acidity of stems and leaves. Common Sorrel (*R. acetosa*) is a perennial found in meadows and pastures throughout the whole of Europe, and is very plentiful in Britain. Its stem is from a foot to two feet high, its leaves arrow-shaped. It is an agreeable salad, and is used in soups and sauces and as an addition to dishes of greens. It is therefore sometimes cultivated in gardens. French Sorrel, or Roman Sorrel (*R. scutatus*), a native of France and Italy, has broader and blunter leaves, and is more frequently cultivated than Common Sorrel, being considered of finer flavour. Sheep's Sorrel (*R. acetosella*) is a very similar plant, but of much smaller size, and its roots run very much under ground, so that it is a very troublesome weed in gardens and fields of poor dry soil, in which it is very common in all parts of Britain. *R. patientia* and *R. sanguinea* are both regarded on the Continent as good spinach plants. For Wood-sorrel, a totally different plant, see OXALIDEÆ. For the Red Sorrel of the West Indies, see HIBISCUS.

Common Sorrel (*Rumex acetosa*).

Sorrel Tree (*Oxydendron arboreum*), a small tree of the natural order Ericaceæ, which grows chiefly on the Alleghany Mountains. The leaves are acid, and are sometimes used for dyeing wool black.

Sorrento (Lat. *Surrentum*), a city of Italy, on the south-east side of the Bay of Naples, on the promontory which separates it from the Gulf of Salerno, 7 miles SW. of Castellamare. It is an archiepiscopal see, and possesses a cathedral. The manufacture of silk and the making of parquetry are extensively carried on. It is celebrated for the mildness and general salubrity of its climate, for its beautiful situation in the midst of orange-groves and fruit-gardens, and for the picturesqueness of the adjacent coast; on these accounts it is much resorted to by summer visitors. In the time of Augustus it was noted for its fine buildings; but few traces of these now exist. Among the Romans the wine of Sorrento was held in high repute. Tasso was a native. Pop. 6089.

Sortes Virgilianæ, a favourite mode of divination among the ancients, in which an oracular answer was found in a doubtful juncture by opening Virgil's *Æneid* at random, and pricking a pin into the book, or taking the first passage on which the eye chanced to rest. Another method was to take a number of his verses, shake them together in an urn, and draw out one, from whose contents to infer good or evil. The ancient Sibylline oracles naturally afforded a subject, and the strange magical reputation early attached to Virgil helped to make his great poem the book most frequently used for this purpose. The mediæval mind read Christianity into Virgil, and consequently found no difficulty in ascribing equal value to the *Æneid* and the Bible for purposes of divination. We are told that Severus fore-read his high destiny in the line, 'Tu regere imperio populos, Romane, memento;' and Gordianus, who was to reign for but a few days, read his doom in the words, 'Ostendunt terris hunc tantum fata, nec ultra esse sinunt.' Gundulf, afterwards bishop of Rochester, and two other monks one day at Caen turned over the pages of a book of the gospels to read their future fortunes, and the Abbot Lanfranc foretold from Gundulf's passage that he should yet become a bishop. Rabelais found his license to escape from the bondage of the convent in the line, 'Heu! fuge crudeles terras, fuge littus avarum;' and we may see all the weakness of this method in the perplexity of the answers it yielded in the great question of Panurge's marriage. Dr Welwood tells us that Charles I. and Lord Falkland once made experiment of their future fortunes at the Bodleian in Oxford, and found passages equally ominous to each. The lines which the king read (*Æn.* iv. 615-620) from Dido's imprecation against Æneas plainly foretold rebellion, defeat, and a shameful death; Falkland opened at Evander's lamentation over the untimely death of his son Pallas (*Æn.* xi. 125-131). Unfortunately for this beautiful story, Aubrey in his *Remains of Gentilisme and Judaisme* tells it of Prince Charles and the poet Cowley at Paris just before the trial of the king. At any rate Cowley himself tells us that he found some light from Virgil about the Scottish treaty, when employed as a secretary in affairs of state; and we read how the Lord Chamberlain used the passage in 2 Chron. xix. 5-8 during Charles I.'s miserable Sunday of hesitation about the execution of Strafford to convince the king that the responsibility really rested upon the judges. Sir Thomas Browne in his *Vulgar Errors* denounces the *Sortes* as an ancient fragment of pagan divination; and Dr Nathanael Home, in his *Dæmonologie* (1650), deplores the loss to the state and the sin to the church engendered through lots by sieves and books.

The early Christian writers denounced divination by lots as magical, and therefore a form of idolatry. Still the practice continued to be common —'per sortes sanctorum,' by the first passage found in the psalter or gospel, the lectionary or sacramentary. St Augustine condemned this as an abuse of the divine oracles, yet preferred to see men turn in this way to the gospels rather than to demons. And we find that an unsought omen from a psalm ended the opposition to the choice of St Martin as bishop of Tours. The *Sortes Apostolorum* was a collection of pious sentences much employed for divination, a bread and water fast of three days being prescribed before using it. A similar use of the Bible long survived amongst Protestants, and indeed is not to this day extinct among people of simple faith in corners of England and Germany. A characteristic instance is told of his own experience by the great Cambridge evangelical leader, Charles Simeon, when downcast about the opposition to his ministry in his earlier years. 'I prayed that God would comfort me with some cordial from His word, and that, on opening the book, I might find some text which should sustain me. It was not for direction I was looking, for I am no friend to such superstitions as the *Sortes Virgilianæ*, but only for support. The first text that caught my eye was Matt. xxvii. 32. . . . Simon was the same as Simeon. What a word of instruction was here, what a blessed hint for my encouragement!' The obstinate survival of this superstition depends upon the naturalness of the notion, where there is a strong conviction of the power and watchful care of an overruling Providence, and a belief in the Bible as the literally inspired hand-book of divine guidance to man. Bibliolatry makes the notion of such divination perfectly rational, and we may well believe that its disuse has been merely a consequence of the decaying respect for the mere letter of Scripture. See Divination, and Magic.

Sorus. See Ferns.

Soteriology, that part of theology which treats of salvation by a redeemer (Gr. *Sōtēr*). See Atonement, Christ, Christianity, Jesus Christ.

Sothern, Edward Askew, comedian, was born in Liverpool, 1st April 1826, and, declining the church, medicine, or the bar, in 1849 joined a company of players in Jersey, and soon afterwards passed into the stock company of the Theatre Royal, Birmingham. From 1852 he appeared in the United States, without much success, until in 1858 *Our American Cousin*, by Tom Taylor, was brought out in New York, with Sothern cast for the small part (forty-seven lines) of Lord Dundreary. The piece was a poor thing, and the character of the English peer as playgoers know it was Sothern's own creation, bit by bit. In November 1861 the play was produced in London, at the Haymarket, and ran for over 400 nights; and it was again and again revived in later years. Sothern essayed many other characters, but he is remembered chiefly as Dundreary; his other most memorable parts were David Garrick in Robertson's comedy, and perhaps Fitzaltamont in *The Crushed Tragedian*; the latter failed utterly in England, but was always popular in America, whither Sothern returned several times. He died in London, 21st January 1881. See the *Memoir* by T. E. Pemberton (1890).

Soto, Ferdinando de. See De Soto.

Sotteville-les-Rouen, a town of France, dept. of Seine-Inférieure, 4 miles by rail S. of Rouen, with railway workshops and cotton industries. Pop. 13,628.

Sou, or Sol. See Solidus.

Soubise, an ancient French family, whose property and title came in 1575 into the house of Rohan by the marriage of their heiress, Catherine de Parthenay, with the Vicomte René II. de Rohan. Memorable as champions of the Huguenot cause were both sons of this marriage, the elder, Henri, Duc de Rohan (q.v.), and the younger son, Benjamin de Rohan, to whom the seigneury of

Soubise fell as heir of his mother. The latter was born about 1589, served under Prince Maurice in the Low Countries, and in the religious war commanded the Huguenots in Poitou, Brittany, and Anjou, and distinguished himself throughout by his reckless courage, especially in the bold attack on the royal fleet in the harbour of Blavet and the occupation of Oleron. When all hope was at an end he found a refuge in England, and died in London childless, 9th October 1642.—In the collateral line of descent was Charles de Rohan, Prince de Soubise, peer and marshal of France, who was born 16th July 1715. His grandmother had been a mistress of Louis XIV., and he himself became a favourite of Louis XV., and early in the Seven Years' War was given the command of an army of 24,000 men, which was utterly defeated by the great Frederick at Rossbach, 5th November 1757. His later exploits were less disastrous; he even won some small successes, and he kept the command until the peace in 1763. After the death of Madame de Pompadour he found the same patroness in Dubarry. When Louis XV. died he was the only one among the courtiers who followed his body to the grave—a piece of loyalty which made the new king retain him in his place in the ministry. He died 4th July 1787, and with him ended the line of Soubise-Rohan.

Soudan, or SUDAN, the Arabic equivalent (*Beled es-Sudan*—i.e. 'Land of the Blacks') of Negroland or Nigritia, a geographical term which in its widest sense embraces the vast region of Africa that stretches from the Atlantic to the Red Sea and the Abyssinian highlands, and from the Sahara and Egypt proper in the north to the Gulf of Guinea, the central equatorial regions, and the Albert and Victoria Nyanzas in the south. This is the home of the true Negro race, though there are various other pure and mixed elements in the population derived principally from Hamitic and Semitic (Arab) stocks. The Soudan in this sense falls naturally into three divisions: (1) *Western Soudan*, comprising the basins of the Senegal, Niger, Benue, and other rivers draining to the Atlantic, and including the political regions known as the French Soudan (see SENEGAMBIA), Sokoto (q.v.), and others; (2) *Central Soudan*, including the basins of the rivers draining into Lake Tsad, and covering the countries of Bornu (q.v.), Bagirmi (q.v.), Kanem, Wadai; (3) *Eastern Soudan*, the rest of the Soudan area east of Wadai, mainly the basin of the Middle and Upper Nile. This portion of the Soudan is also frequently styled the *Egyptian Soudan*.

Until 1882 the Egyptian Soudan formed one ill-organised province, with its capital at Khartoum. But in that year it was subdivided into four sections: (1) *West Soudan*, including Dar-Fûr (q.v.), Kordofan (q.v.), Bahr-el-Ghazal (the province on a western tributary of the White Nile, south of Kordofan), and Dongola (q.v.); (2) *Central Soudan*, comprising Khartoum (q.v.), Sennaar (q.v.), Berber, Fashoda (south-east of Kordofan), and the Equatorial Province, stretching along the Upper Nile to the great lakes; (3) *East Soudan*, along the Red Sea, including Taka, Suakin, and Massowah; (4) *Harar*, east of Abyssinia and north of the Somali country, abutting on the Gulf of Aden. This wide region differs considerably in physical features in its different parts. All the regions watered by the Nile and its tributaries (Taka, Sennaar, Fashoda, Bahr-el-Ghazal, and the Equatorial Province) possess highly fertile soil, capable of yielding immense quantities of cotton, durra, indigo, sugar, rice, maize, tobacco, fruits; while Kordofan and Dar-Fûr are bare and waterless, except in the rainy season, after which their wide grassy steppes give sustenance to numerous herds of camels, cattle, sheep, and goats. Besides the products mentioned, ivory, ostrich-feathers, caoutchouc, salt, cloth, gums, iron, gold, honey, wax, and hides are important articles of internal traffic and foreign trade. The area of this portion of the Soudan has been estimated at 2½ million sq. m., and the total population at about 15,000,000. Of these three fourths are of Negro descent, and mostly pagans or nominal Mohammedans; the rest are of Hamitic or Semitic origin and are fanatical in their adherence to Islam. The Egyptians established themselves at Khartoum in 1819, and during the next fifty years gradually extended their power over the provinces lying west and south of that city, and were more especially active during the third quarter of the century. In 1874 Dar-Fûr was conquered with help of Zebehr Pasha, a noted slave-hunter. Not receiving, however, the reward he conceived himself entitled to, he provoked insurrections in that district and in the Bahr-el-Ghazal province (1877-79), which were successively crushed by Gordon and Gessi. But in 1882 the Mahdi (q.v.) again raised the flag of revolt, and preaching a religious crusade overpowered the distant Egyptian garrisons, annihilated the Egyptian forces led by Hicks Pasha, cut off Emin Bey in the Equatorial Province, and shut up in Khartoum Gordon (q.v.), whom the English government had sent out to restore peace by friendly means; while his lieutenant, Osman Digna, after defeating the Egyptian army commanded by Baker Pasha, prevented the English from penetrating into the interior from Suakin and the Red Sea. Gordon's mission ended in disaster, in spite of the heroic efforts of General Wolseley's corps to relieve him, and with the fall of Khartoum perished every shred of Egyptian influence in the Soudan. Since then much anarchy has prevailed amongst the native tribes, and the followers of Sheik Senussi (q.v.) increased their power in Kordofan and the adjacent districts. In 1892 the Mahdi's successor was besieged by the Senussi in Omdurman, to which place, just across the Nile from Khartoum, the headquarters of Mahdiism had been transferred.

Soufflé, a light and agreeable dish, consisting chiefly of the whites of eggs, to which other ingredients (chocolate, cheese, vanilla, orange-flower water, rose-water, various essences, &c.) are added, to give consistency, flavour, and variety. The materials have to be agitated with a whisk until the whole is in a creamy froth, which is then baked in a soufflé-pan, made of such a form as to fit into a dish or proper holder that can be sent to table and quickly handed round.

Soul, a term used with various significance both in philosophical terminology and in the language of everyday life. Soul is sometimes the immaterial and immortal part of man as opposed to his body; soul is sometimes distinguished from intelligence as the resolute, energetic, emotional from the calmly contemplative; and when soul and spirit are contrasted, the soul is the lower phase of conscious life (sometimes the animal soul) as contrasted with the highest, noblest, and godlike element. A like confusion obtains in other languages; the German *seele* and *geist* are opposed nearly as life principle to mind, and as the emotional to the intellectual and spiritual. The confusion dates from the early times of Greek philosophy. In general, *psyche* (usually translated 'soul') is opposed to *nous*, 'intelligence,' and also, especially in religious philosophy, to *pneuma*, 'spirit,' the divine element in man. Plato (q.v.) divided the soul into (1) the rational, (2) the spirited or irascible, and (3) the appetitive elements. With Aristotle the *psyche* is practically the vital principle in plants as well as animals. In Neoplatonism (q.v.; and see also PLOTINUS) the psychical side of man was treated with disrespect as the part to be mortified. The doctrine of a world-soul has its roots in early speculation (see ANIMA MUNDI), and connects with some types of Pantheism (q.v.); see also MICROCOSM. Opposing views as to the origin of the individual soul, creationism, and traducianism are explained in the article dealing with the belief in Pre-existence (q.v.). The Transmigration (q.v.) of the soul is separately treated. See also the articles PSYCHOLOGY, PERSONALITY, IMMORTALITY, APPARITIONS, SECOND SIGHT, HELL, ANIMISM, and those on the great authors named at PHILOSOPHY.

Soulouque. See HAYTI.

Soult, NICOLAS-JEAN DE DIEU, Duke of Dalmatia, and Marshal of France, was born the son of a notary at Saint-Amans-la-Bastide, in the dept. of Tarn, March 29, 1769. In 1785 he enlisted as a private in the Royal Infantry regiment, and was only sergeant after six years' service. Thereafter, however, his rise was rapid; in 1792 he became adjutant-major, and his conduct at Fleurus gained for him (October 1794) the brevet of general of brigade. From 1794 to 1799 he was in constant service on the eastern frontier and in Germany, and in the retreat after the defeat of Stockach (March 25, 1799) it was his able handling of the rear-guard alone that prevented the annihilation of the French army. The new chief Masséna made him general of division (April 1799), and owed to his courage and capacity much of the glory of his Swiss and Italian campaigns. In 1802 Soult was appointed by Napoleon one of the four colonels of the consular guards; in 1804 a marshal of France. He led the emperor's right wing in the glorious campaign closed with the crowning victory of Austerlitz, which he decided by piercing the Russian centre. He also did good service in the Prussian campaign, and took an important though not a prominent part in the Russian campaign of 1806-7, and after the peace of Tilsit was created Duke of Dalmatia. Soult was next placed at the head of the second corps in Spain, pursued the retreating British, attacked them at Corunna, and, though repulsed, forced them to evacuate the country and leave their stores behind. He then conquered Portugal, and governed it till the sudden arrival of Wellesley at Coimbra made him retreat rapidly to Galicia. In September 1809 he became commander-in-chief in Spain, gained a brilliant victory at Ocaña (18th November), and at the commencement of the following year overran and subdued Andalusia, continuing to command in person the southern army. In attempting to succour Badajos, which he had captured and garrisoned (March 11), he was defeated by Beresford at Albuera (May 16, 1811). After the battle of Salamanca and the advance of the British on Madrid, Soult, mortified at the obstinacy of Joseph Bonaparte and the rejection of his admirable plans for transferring the theatre of war to Andalusia, demanded and obtained his recall; but Napoleon, as soon as the tidings of Vittoria reached him, sent him back to the command in Spain, as the only captain capable of turning the tide of ill-fortune. By brilliant tactics he neutralised the consummate strategy of Wellington, and reduced the seven months' campaign to a mere trial of strength, the defeats which he sustained at Orthez and Toulouse being due to the superiority of the British soldiers, not of their general. With his usual suppleness of character, he became an ardent royalist after the abdication of Napoleon; but on the return of the latter from Elba he threw over Louis XVIII. to become major-general of the imperial army. After Waterloo he rallied the ruins of the army at Laon, and at the council of war (July 3) coincided with Carnot as to the uselessness of further resistance. He was banished and not recalled till May 1819, but within a few years he was restored to all his former honours. In 1838 he was sent as ambassador to England to the coronation of Victoria, and was received by Wellington with warmth and by the nation with enthusiasm. In 1845 he retired from active duty, and was honoured with the appointment of 'Marshal-general of France'—a rank held before him only by Turenne and Villars. He now retired to Soultberg, his château near his birthplace, where he died, November 26, 1851.

See Soult's *Mémoires*, written in 1816 at Düsseldorf (3 vols. 1854); also Napier's *History of the Peninsular War*; Thiers's *Histoire de la Révolution et de l'Empire*; Salle's *Vie Politique du Maréchal Soult* (1834); and Combes, *Histoire Anecdotique* (1870).

Sound, in ordinary language, is that which appeals to us through our organs of hearing. Experience teaches us that almost every sound can be traced to a source outside of us, and that as a rule the sound is characteristic of the source from which it comes. Different voices are easily recognisable, and there is no difficulty in distinguishing a trumpet-call from a violin-note. Here we have brought out the *quality* or *timbre* or colour of a sound. Another very obvious characteristic is the *pitch* of a sound. On it the whole theory and practice of music is based. Even the most unmusical ear can distinguish between a deep-toned note and a shrill one, between, for example, the extreme notes on a piano or organ. Then there is the question of the *intensity* or loudness of a sound. In terms of these three fundamental characteristics all differences of sound can be expressed. It is the object of the science or theory of sound to investigate the physical or mechanical nature of whatever under suitable conditions can be heard by the ear, and to express in terms of motion of matter these three ever-present characteristics—quality, pitch, and intensity.

Generally speaking, the air is the medium through which sound travels towards us. Whatever be the sound-producing body, it must first transfer something to the air, which in its turn conveys a corresponding something to our ear. Within us the sensation produced is a purely subjective one, and must not be confused with the objective cause existing outside of us. There is, however, a distinct relation between the two; for when the external conditions are physically identical, so are the resulting sensations. The very fact that air can transmit to us such a variety of sounds shows that it is capable of responding more or less completely to the varied characteristics of the sound-producing body. The necessary condition for the production of sound is that the body must, by its own vibrations or in some other way, set the air into vibration. Bells, tuning-forks, violin-strings, and drums are familiar instances of vibrating bodies; but if these are made to vibrate *in vacuo* no sound will be heard. Vibrating in air they give forth their appropriate sounds. In the Siren (q.v.) we have an instrument which produces sound by breaking up a continuous blast of air into a succession of pulses. The instrument is valuable as proving that the pitch of a note depends on the number of pulses per second. The faster the siren spins, the more quickly the pulses follow each other, the greater is the *frequency* or number of pulses per second, and the higher is the pitch, as the ear at once tells us. The same fact can be proved by holding the edge of a card against the teeth of a revolving toothed wheel. If the wheel is going fast enough, the successive noises of the card as it frees itself from each tooth and impinges itself on the next succeeding are no longer distinguishable, but coalesce to produce a note of definite pitch which rises as the wheel rotates faster. Now it may be shown that, when the ear is satisfied that the notes produced by a siren and a tuning-fork have the same pitch, the number of pulses given by the siren in one second is exactly equal to the number of vibrations of the tuning-fork in the same time. Thus the vibrating tuning-fork transfers to the air a series of pulses timing accurately with the vibrations. It is not difficult to see how this takes place. As the forks vibrate to and fro they push the air first on one side and then on the other; and just as a hand moved slightly to and fro in water starts a series of waves travelling outwards along the surface, so the tuning-fork starts in the air a series of waves of condensation and rarefaction which travel outwards through the air. In the case of the water-waves gravitation supplies the force which, by its tendency to keep the surface level, gives the power of recovery that is indispensable to all wave-motion. In the case of the sound-waves the air's own Elasticity (q.v.), or power of resisting change of bulk and of recovering completely its original density, is the essential factor in producing and sustaining the wave-motion (see WAVE).

The essential features of the wave-motion in the air may be indicated by the behaviour of a row of points, each of which oscillates to and fro about its mean position. The time or period of oscillation is the same for all; and we shall suppose the oscillations to be of the simplest type known as Simple Harmonic Motion (see WAVE). When at rest the points are all at equal intervals apart, as in fig. 1, *a*. When in motion so that each point moves through its mean position a little later than does the immediately preceding point, then the points will be crowded together in some regions and widely distributed at others (fig. 1, *b*). As the points continue their oscillations the configuration will not remain steady, but will move along among the points (fig. 1, *c* and *d*). Any given region will become alternately more crowded and less crowded, a region now of condensation, now of rarefaction. This ever-changing condition, which we have supposed to be the characteristic of a row of points, may easily be imagined to be possessed by a swarm of space-filling particles; and, from the analogy of the circular ripples which expand outwards over the surface of a lake which has been disturbed by a stone being dropped into it, we can readily picture a succession of spherical waves of condensation and rarefaction radiating out through air from the source of disturbance, in the present instance the source of sound. The mode by which the condensation or rarefaction is passed on from one region of air to another may be explained as follows: Because of its elasticity air resists compression and will tend to recover its original density as soon as the compressing force is removed. But because of its inertia it will, if left perfectly free, overdo the recovery—just as a pendulum when drawn aside and let go swings to the other side of its natural position of rest. Now if any small region of air undergoes rarefaction it can only do so by itself expanding and thereby compressing the surrounding layer of air. But as it, so to speak, swings back through its condition of normal density to a state of condensation, the surrounding layer will swing from its state of condensation to a state of rarefaction, that is, expansion, compressing thereby in its turn the next encompassing layer of air. This second layer, having thus acquired an oscillatory character, will in the same way impress the next layer with a like character, and so on indefinitely.

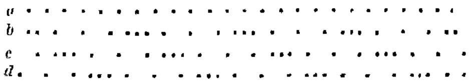

Fig. 1.

Returning to the case of the tuning fork, we see how the energy of its vibrations is gradually transferred to the air and transmitted through it to the farthest limits at which the sound is heard, if not farther. Thus the motion of the tuning-fork gradually decays, and the intensity of the sound heard at any given distance simultaneously diminishes. Ultimately the sound dies away, and the tuning-fork comes to rest. What is called the intensity of a sound depends in some way upon the degree of agitation communicated to the air—in accurate language, upon the vibratory energy existing in the air at the place where the sound is heard. Now it is a familiar experience that with great variations of intensity the pitch of a sound remains unchanged. The pitch depends upon the *number* of vibrations per second, and the intensity upon the *energy* of vibration. We find then that within wide limits the extent or amplitude of the vibration, or (as in air) the range through which the density may vary, does not affect the periodic time of the vibration. The quantitative relation between the energy and the amplitude, and therefore between the intensity and the amplitude, is that the former varies as the square of the latter. With double the amplitude we have four times the intensity, with half the amplitude one-fourth the intensity. That the intensity falls off at a much quicker rate than the amplitude is at once evident to any one closely inspecting the diminishing range of motion of a tuning-fork and at the same time paying attention to the decreasing loudness of the tone. The ear is by no means so sensitive in comparing intensities as it is in comparing pitches. When two notes are of very different pitch it is often difficult to say which is the louder.

We now pass to the consideration of the quality of a musical sound. A tuning-fork gives a colourless inexpressive sound, whose one useful property is the constancy of the pitch. When sounding the same note the pianoforte, the violin, the trumpet, the clarionet, and the human voice all impart their own peculiar flavour, which is readily recognised by the ear. Not only so, but we can distinguish different pianofortes, different violins, different voices, and so on. These differences of quality cannot depend on the frequency or number of vibrations per second, for that determines the pitch; nor upon the energy of vibration, for that determines the intensity. Quality, in fact, can depend only on the internal nature of the vibration. This may be shown synthetically, as König has done, by making siren discs, each perforated with its own peculiar shape of hole, but all identical as regards number of holes and rate of rotation. It is evident that if the blast of air is broken up into successive portions which have issued through, say, triangular instead of the usual circular holes, the *form* of the pulses which build up the note will be changed. And such a change is recognised at once by the ear.

Most instructive in this connection are the laws of vibration of stretched strings. If we fix one end of a pretty long rope to a wall, and, with the other end in the hand, keep it in a stretched condition free of the floor, we may observe any slight disturbance given to it running as a solitary wave along the rope and back again after reflection at the wall. The tighter the rope is stretched the quicker will this disturbance travel to and fro along it. It is not difficult to show that the speed at which such a disturbance or wave will travel along a stretched cord depends on the tension (T) and on the mass (m) per unit-length of the cord, being given by the simple formula $v = \sqrt{(T/m)}$. Suppose we have such a stretched cord of indefinite length, and that a series of exactly equal waves are running along it from left to right, as shown in fig. 2, *a*, in which the straight line indicates the undisturbed position of the string. Now let there be propagated along the string from right to left an exactly equal series of waves, which, if existing alone, would throw the string into some such form as shown in *b* (fig. 2).

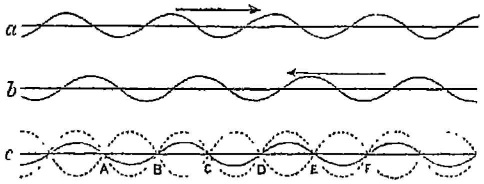

Fig. 2.

The superposition of these two exactly similar series of waves propagated in opposite directions gives rise to a resultant motion indicated in *c* (fig. 2). Here the points ABCDEF, being once at rest, are always at rest; since, whatever be the displacement due to the *a* waves, an exactly equal and opposite displacement is produced by the *b* waves, now and forever. Intermediate points, however, will move up and down between the limits indicated by the dotted loops in *c* (fig. 2). The string, in fact, will vibrate in segments whose ends are fixed at the points ABCDEF. The segments will be, at any instant, alternately above and below the undisturbed position of the string. The motionless points are called *nodes;* and it is evident that we may fix any two of them, and cut away all the string lying beyond these chosen nodes without in any way affecting the motion of the part lying between them. If we fix two contiguous nodes, for example A, B, we have a definite length of string vibrating as a whole. If A and C are fixed we get twice that first length of string vibrating in two segments; if A and D, we have three times the length vibrating in three segments; if A and E, four times the length vibrating in four segments; if A and F, five times the length vibrating in five segments; and so on. Now all these are simply different ways of producing exactly the same vibration, so that a note which is given by one length of stretched string vibrating as a whole may be given by L lengths of a similar string similarly stretched, vibrating in L segments. But we may have this string of length L itself vibrating as a whole. We have merely to suppose the oppositely directed series of waves to be L times longer than those shown in fig. 2 (*a*, *b*). If n is the frequency of any vibration, and l the wave-length or distance from crest to crest, it is easy to see that a given wave will travel over a distance nl in one second. That is, we have $nl = v = \sqrt{(T/m)}$, a quantity depending only on the tension and mass of the string. Consequently, if we double the wave-length we halve the frequency; if we halve the wave-length we double the frequency; and so on. Generally then the frequency of vibration of a string of given tension and density varies inversely as its length. This is the principle on which all instruments of the violin and guitar types are played. The player, by pressing the string down with the finger at different points, can shorten the string in the required ratio, thereby producing a correspondingly higher note.

From what precedes we see that a stretched string, which vibrates as a whole, say, 100 times per second, can also vibrate 200 times per second in two segments, 300 times per second in three segments, and, in general, n hundred times in n segments, if the segments are not too short. By lightly touching, without pressing, a violin-string at the proper point, so that that point is made a node, any of these higher notes (overtones) may be obtained. This is a very common practice in playing the violoncello. Not only, however, may a string be so made to utter any of the overtones, but it is practically impossible to prevent some of them sounding along with the fundamental note. It is, in fact, upon the presence of these overtones that the quality or character of the sound depends. They give the *form* to the vibration. In fig. 3 we see how the form of the wave is changed by superposing upon a given vibration the first and second overtones, having frequencies twice and three times the frequency of the fundamental tone. The musical relations of these overtones of stretched strings are discussed under HARMONICS (q.v.). The harmonics of a note are the simple harmonic vibrations

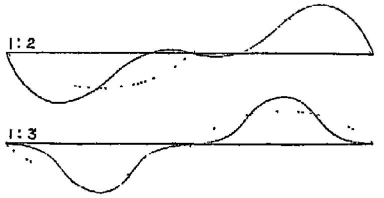

Fig. 3.

into which, according to Fourier's analysis, any steadily recurring periodic motion can be decomposed. The prime or fundamental tone is the first harmonic; and higher harmonics are all overtones. But, as we shall see hereafter, all overtones are not necessarily harmonics.

Air-columns, such as we have in organ-pipes (see ORGAN), vibrate according to laws very similar to those which rule the vibrations of strings. The frequency of the note is inversely as the distance between two successive nodes. One essential difference is that the ends of a stretched string must be nodes, whereas in pipes one or both ends may be *loops*, where the velocities experience their maximum change and the pressure is invariable. In the open organ-pipe both ends are loops, between which one node at least must exist if a sound is produced. This gives the fundamental vibration, and may be diagrammatically indicated, as in fig. 4, *a*. The wave-length is (approximately) double the length of the tube. The second harmonic is produced when two nodes intervene, as in *b* (fig. 4); the third when three nodes intervene, as in *c* (fig. 4); and so on. The wave-lengths of these are respectively the length of the tube and two-thirds the length of the tube. Hence, if the fundamental tone has frequency 100, the second has frequency 200, the third 300, and so on. In the closed or stopped organ-pipe, again, one end is a node and the other a loop. In fig. 5, *a*, we have a diagrammatic representation of the prime tone, whose wave-length is (approximately) four times the length of the tube. Thus by simply stopping the one end of an open organ-pipe we lower the prime tone a whole octave. The next possible mode of vibration is indicated in *b* (fig. 5), in which are two nodes. Here the wave-length is 1⅓ times the length of the tube. In the next mode, with three nodes (fig. 5, *c*), the wave-length is ⅘ of the length of the tube; and so on to higher harmonics. If the fundamental tone of a closed pipe has frequency 100, the next possible harmonic will have frequency 300, the next 500, and so on. Thus in any note uttered by an open pipe all the harmonics may enter; but in a closed organ-pipe only those of odd number can be present. This lack of the even harmonics gives a curious nasal quality to the tone of the closed organ-pipe. By overblowing we may so accentuate the second harmonic in the open pipe as to make it sound a note appreciably an octave higher than the fundamental note. By overblowing the closed pipe the pitch of the note jumps up an octave and a fifth. With flutes and whistles similar effects may be produced.

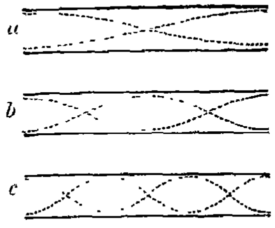

Fig. 4.

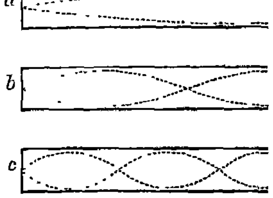

Fig. 5.

A tuning-fork is a vibrating bar whose one end is a node. In producing its fundamental tone each prong vibrates so that there is no other node, as in fig. 6, *a*. The next possible mode of vibration is when a second node exists, as shown in fig. 6, *b*. This first overtone is not related to the fundamental tone according to the harmonic series already given for strings and air columns. For example, if the fundamental tone of the tuning-fork is C of the bass clef, the first overtone is two octaves and 7·7736 mean semitones higher—i.e. a little flatter than G♯ above the treble C. In the case of stretched membranes, vibrating plates, and bells similar complexities hold; and it is impossible to get from them overtones harmonically related to the fundamental tone and to one another. There is no doubt, however, that the characteristic clang of a bell is due to the presence of these anharmonic overtones; and the art in bell-making is to prevent them having a pronounced discordant effect on the ear. By careful manipulation the first anharmonic overtone of a large-sized tuning-fork may be made to sound instead of the fundamental tone, and not infrequently it may be heard along with it. In this latter case it rapidly dies away, and the tuning-fork continues to utter a pure tone of the simplest harmonic type. When strings or columns of air are vibrating, the harmonic overtones may be picked out by the ear with tolerable ease after a little practice. Their presence may, however, be made evident to the most unmusical ear by the use of resonators.

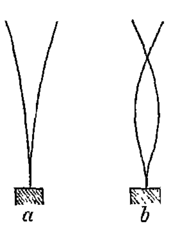

Fig. 6.

The function of a resonator is to reinforce the intensity of a note produced by some vibrating body in its neighbourhood. The principle is made use of in all musical instruments. For instance, in the violin the greater part of the energy of vibration of the string does not pass directly to the air, but indirectly through the body of the violin, which vibrates with the string. The sounding-board of a piano plays the same rôle, being set into vibration by the impacts of the waves upon the terminal fixed points of the strings. In these and similar cases a greater mass of air is influenced by the vibrations of the system, the energy originally given to the string is more quickly transferred to the air, and the result is increased intensity. The word resonator is, strictly speaking, applied to a body which resounds to one note only or to one of a definite harmonic series. If a tuning-fork be held in front of the lip of an organ-pipe, one of whose own harmonics has the same pitch as the note of the tuning-fork, the sound uttered by the tuning-fork will be distinctly reinforced. This reinforcement will not occur in the case of a tuning-fork having no harmonic relation to the pipe. The pipe in the above case acts as a resonator. Again, hold down any note on the piano so as to leave the corresponding strings free, and then strike the note an octave lower, or an octave and a fifth, or two octaves lower. Release this latter note, so that its strings become damped, and the former note will be heard distinctly as if it had itself been struck. Its intensity may be reinforced again and again by repeated striking of a lower note of which it is an harmonic. Here the strings of the note that is being held down act as resonators to the corresponding harmonic of the note that is struck. The same effect may be produced by singing a suitable note, or playing it on some other instrument. The boxes to which large tuning-forks are attached are so shaped that the mass of air within them vibrates naturally to the note of the tuning-fork. And just as a pendulum or ordinary swing may be made to describe larger and larger arcs by properly timed impulses, so a resonator responds to the timed pulses of the note to which it is tuned. Helmholtz's spherical resonators, tuned to the successive harmonics of a particular note, are an indispensable part of the equipment of a physical laboratory. Each is a hollow sphere provided with two apertures diametrically opposite each other. The smaller aperture is made in the form of a small projecting tube which can be fitted close into the ear. Through the other and larger aperture the outside disturbance sets the mass of air inside the sphere into vibration. As an example of their use, take the case when the note to which one of the resonators is tuned is sounded by (1) an open organ-pipe, (2) a closed organ-pipe. By placing in turn each resonator to the ear we readily convince ourselves that the successive harmonics are all present in the sound of the open organ-pipe, but that with the closed pipe the even harmonics are absent. When the proper resonator is placed behind a tuning-fork the sound becomes powerfully reinforced. By taking advantage of this principle Helmholtz proved synthetically that vowel-sounds of the same pitch have different harmonics present. By means of the Phonograph (q.v.) Jenkin and Ewing analysed the vibrations produced by vowel-sounds at various pitches; and their results show that the relative intensities of the principal harmonics present in any given vowel-sound vary with the pitch.

As with all forms of wave-motion, sound may be reflected (see ECHO) and refracted. When a string or air-column is thrown into a steady state of vibration with nodes occurring at regular intervals there is in reality a reflected wave, which, travelling backwards along the vibrating substance, interferes with the forward-travelling wave in the manner already described. Interference (q.v.) is also shown by the phenomenon of beats.

The existence of beats is determined by the coexistence of two notes differing very slightly in pitch; and the number of beats per second is simply the difference of the frequencies. Because of the absence of upper harmonics in the note given by a tuning-fork, the phenomenon is produced in its purest form by means of two tuning-forks originally in unison but thrown slightly out of tune by weighting the one tuning-fork with a small piece of wax attached to it. If the tuning-forks, for example, have frequencies 300 and 302, there will be heard two beats per second—i.e. the intensity of the resultant sound will vary from zero to a maximum and back to zero again twice every second. The reason of this will be easily seen if we consider the resultant effect of the two sets of waves at different times. For, since the two sounds have the same velocity, it is clear that across any surface set in the path of the rays of sound the higher note will transmit two more waves per second than the lower note, or one more wave in half a second, or half a wave extra in a quarter of a second. Suppose that at the beginning of the second chosen the nearly equal waves combine crest to crest and trough to trough, so as to produce an increased intensity; then a quarter of a second later the slightly quicker vibration will have gained half a wave-length on the other, crest will fall with trough and trough with crest, and little or no vibratory motion will be the result. At the half second, crest and crest will again coincide, and the resultant sound once more reach a maximum; and so on indefinitely. The transition from maximum to minimum loudness is of course gradual. If notes in which higher harmonics exist are used the beating is not so simple. For example, with open organ-pipes tuned to frequencies 300 and 302, not only will the primes beat twice a second, but the second harmonics 600 and 604 will beat four times a second, the third harmonics six times a second, and so on. There is generally no difficulty getting beats from a pianoforte note, since the two or three strings that belong to the note are rarely in accurate tune.

In general if m and n are the vibration numbers of two notes sounding together which give beats, $(m - n)$ will be the number of beats per second. If this beating does not occur oftener than two or three times a second the ear is not distressed. Rapid beating, however, produces very unpleasant sensations even after it has reached a rapidity too high to be counted. When the difference of frequencies $(m - n)$ is greater than 25 or 30, the note of frequency $(m - n)$ is heard in addition to the two original notes. There is no difficulty in hearing this differential tone, as it is called, when the two notes are sufficiently loud. On instruments giving sustained sounds, such as the organ, harmonium, and concertina, very marked differential tones are produced; and to an ear trained to their perception they are recognisable on the piano. When the difference of the frequencies lies between 30 and 100 the rattling of the beats may often be distinguished from the low hum of the differential tone; so that we are not warranted in regarding these two phenomena as of the same nature. By bringing the two notes by different courses to the two ears we can hear the beats, but cannot hear the differential tone. Moreover, in addition to the differential tone $(m - n)$, there are other differential tones of frequencies $(2m - n)$, $(m - 2n)$, &c., and also at times a weak summational tone of frequency $(m + n)$. This last-named tone was discovered by Von Helmholtz, to whom we owe the complete discussion of the origin and significance of these Combinational Tones, as they are collectively termed. Two kinds are distinguished by him. If the vibrations transferred from the vibrating body to the air are very large the simple law of superposition may not hold. A simple pendular vibration, such as a tuning-fork may give, will when transferred to the air lose to some extent its simple harmonic character, and higher harmonics will enter in. If two simple pendular vibrations act powerfully on the air combinational tones will be produced in addition to the higher harmonics of the two original notes. These combinational tones existing in the powerfully disturbed air can be reinforced by use of resonators. Combinational tones of the second kind cannot be so reinforced, since they are produced in the ear itself. They are due to the asymmetric character of the drum of the ear, which cannot respond to two coexisting vibrations without producing combinational tones. The frequencies of these combinational tones, whether of the first or second kind, are all included under the general formula $Mm \mp Nn$, where m and n are the frequencies of the original notes, and M and N are integers from zero upwards. As experiment shows, only the first few integers are of any importance, and no summational tone of higher order than $m + n$ (M and N both unity) has ever been heard. As an example, take two notes having frequencies 200 and 315. Their principal combinational tones will have frequencies 115 $(315 - 200)$ and 85 $(2 \times 200 - 315)$. This latter may be regarded as the differential tone between the lower prime and the first combinational tone. These two tones can both be heard if the intensities of the sounds are sufficiently strong. Both theory and experiment show that the comparative intensity of combinational tones grows rapidly as the intensities of the real notes are increased, and also that combinational tones of low pitch are most prominent.

As first brought out clearly by Helmholtz, combinational tones are of peculiar interest when the two notes form a consonant interval. Thus, take any two notes a musical fourth apart. Their vibration numbers may be represented by $3n$ and $4n$. Their principal differential tone will have the frequency n $(= 4n - 3n)$, and will therefore form the fundamental tone of which the given two are harmonic overtones. Again, take any perfect triad (*do*, *mi*, *sol*) having frequencies $4n$, $5n$, $6n$. Each successive pair gives the same differential tone n; the first and last together give the differential tone $2n$. Thus we hear the low tone which is harmonically fundamental to all, and its octave. In some cases the differential tone becomes so loud that the real notes which are being sounded become merged in it as upper harmonics. If the notes of the triad are not in perfect tune the differential tones will not be harmonically related. On an organ tuned in equal Temperament (q.v.) the chord built upon the treble C consists of notes having frequencies 522, 657·7, 782·1 (see PITCH). The two lowest differential tones have frequencies 135·7 and 124·4—notes which, sounding together, produce 11·3 beats per second. The ear that has accustomed itself to the pure harmony of the perfect triad will easily recognise a certain dissonance in the triads given by pianos and organs.

Beats always mean the coexistence of two notes of nearly the same frequency. If on any organ or harmonium any note and its fifth are struck together beats are heard. It is indeed by getting rid of these beats that we finally effect a perfect tuning of say two contiguous violin-strings. These beats on the tempered instruments are due to the fact that the interval is not a true fifth, so that the higher harmonics which are present cause beating combinations. This is shown by comparing the first three harmonics of notes which form (1) a perfect fifth and (2) a tempered fifth.

Perfect Fifth.			Tempered Fifth.		
C.	G.	Beats.	C	G	Beats.
522	783	..	522	782·1	..
1044	..	..	1044	..	..
1566	1566	0	1566	1564·2	1·8
&c.	&c.	..	&c.	&c.	

Similar results may easily be obtained for all tempered intervals, if the higher harmonics exist in sufficient strength. We may, however, make use of the combinational tones in producing beats. For instance, by the rule given above, we get for the first combinational tones 260·1 and 261·9, which beat also 1·8 times a second. The second combinational tone is intensified by the actual presence of the second harmonic of C; and we can make the beating still stronger by sounding the octave along with C and G.

All vibrations in air of sufficient intensity and suitable frequency produce sound-sensations. The highest frequency which gives an audible sound is about 70,000. This is much higher in pitch than the highest notes used in music. For example, the frequency of the highest note on the pianoforte falls short of 4000. Very high pitched sounds near the limit of audibility are very disagreeable to the ear; and sounds which are heard by one person may be, because of their high pitch, quite inaudible to another. There are many noises of whose pitch it is impossible to say anything definite. They are no doubt confused mixtures of tones of fluctuating pitch. König has pointed out that the peculiar quality or timbre of trumpet notes and other notes of piercing quality is in great measure due to a fluctuating character in the vibration. The various overtones, both harmonic and anharmonic, do not combine with the prime in a steady periodic manner. Anharmonic overtones must of necessity produce fluctuations in the periodic character of the note; and the theory of quality cannot be complete without taking their existence into account. In this direction Helmholtz's theory requires extension.

Of great value and interest are Helmholtz's investigations on the forms of vibration of strings, especially of violin strings. If we can experimentally determine the form of the wave into which the string is thrown when bowed, we can by Fourier's mathematical process calculate the harmonics that enter in. Helmholtz solved the problem by viewing through a microscope the motion of a small white speck at different points of the string, the microscope itself being attached to the vibrating end of a tuning-fork, and being so made to execute a simple harmonic motion at right angles to the direction of vibration of the white speck. The principle of the method is identical with that introduced by Lissajoux in obtaining what are known as Lissajoux's Figures. Two tuning-forks, with bright reflecting surfaces fixed to their vibrating ends, are arranged so that while one vibrates to and fro vertically, the other vibrates to and fro horizontally. A beam of light is reflected from the one upon the other, and after a second reflection is focussed sharply upon a screen or viewed in a telescope. When either fork is vibrating alone the image on the screen will vibrate also along a straight line. But when both are vibrating together the light spot on the screen will execute the motion which is the resultant of the two mutually perpendicular vibrations. Definite figures are obtained only when the two forks are tuned accurately in unison, or by some simple interval apart. For example, if the two forks give the same note the figure on the screen will be an ellipse or one of its extreme forms, the circle or straight line. If the forks are *very slightly* out of tune—imperceptibly so to the ear—the ellipse will gradually change shape, passing from the circle to the straight line. The figures obtained when the ratio of the frequencies is as 1 : 2 (the octave), 2 : 3 (the fifth), 3 : 4 (the fourth), and so on, are very beautiful; and if the interval is just short of perfect tuning the gradual passing of the figure through a series of related but slightly differing forms is very instructive. The experiment is valuable as giving an optical demonstration of the laws of combination of vibratory motions in lines inclined to one another. Compare the explanation of elliptic and circular Polarisation (q.v.) of light.

Although sounds come to our ear through the air or other fluid as waves of compression and rarefaction, they may have their origin in vibrations of quite a different type. In solid substances there are distortional waves as well as compressional waves. In a pure distortional wave the substance changes form and does not change bulk. Its existence depends upon the Rigidity (q.v.) of the substance. In gases and liquids only compressional waves can exist, and these depend upon the compressibility (see COMPRESSION). When a bar, stretched string, or plate is set into vibrations a certain kind of elasticity is brought into play, and a certain strain produced, which in general involves both change of form and change of bulk. Corresponding to this there is an appropriate stress whose ratio to the strain is the coefficient or modulus of elasticity upon which the velocity of the wave depends. Calling this modulus E, we find for the velocity of a vibratory wave the expression $V = \sqrt{E/D}$, where D is the density of the substance set into vibration.

This formula was first applied by Newton to the case of air. Assuming Boyle's Law (see GAS), he obtained the expression $\sqrt{P/D}$ for the velocity of sound, where P is the pressure. But when the proper numbers are put in the velocity is found to fall short of its true value by about 180 feet per second, or by one-sixth of the whole. Newton's assumption is in fact false. Boyle's Law holds only when, throughout the changes of pressure and density, the temperature remains constant. But in the rapid condensations and rarefactions which accompany audible sounds the temperature varies, increasing during condensation and decreasing during rarefaction. Now rise of temperature means increase of pressure and fall of temperature decrease; so that the result of these temperature changes is to increase the forces at work—i.e. to increase the elasticity. Laplace first made this necessary correction to Newton's calculation. We must in fact multiply the pressure by 1·41, which is the square of 1·2 nearly. The complete theory gives for the velocity of sound in dry air at a temperature of $t°$ F. the value

$$V = 1122 + 1{\cdot}09\,(t - 60) \text{ feet per sec.},$$

which is as near as may be to the mean of experimentally determined values.

The quantity E is the same for all the true gases. Hence the velocity of sound in gases varies inversely as the square root of the density. In other words, a given wave-length will vibrate proportionately faster. Thus, if an organ-pipe be blown with hydrogen gas in it instead of air, the note will leap up nearly two octaves in pitch, since the density of air is 14·4 times that of hydrogen.

In the case of any liquid the quantity E is the reciprocal of the compressibility, which is not appreciably affected by slight changes of temperature. For water the density is unity, and E is $2·08 \times 10^{10}$. Hence V = 144,000 centimetres (4730 feet) per second. Colladon's value, determined by experiments on the Lake of Geneva, was 143,500. Thus sound travels four times faster in water than in air. In the case of solids, in the form of thin rods or wires, waves of compression will travel at still higher speeds. The quantity E is practically Young's modulus of elasticity. In steel $E = 2·14 \times 10^{12}$, and D = 7·85; hence V = 522,000 centimetres (17,130 feet) per second, or nearly sixteen times the velocity of sound in air.

The standard book on Sound is Lord Rayleigh's *Theory of Sound* (2 vols. 1877–78). Tyndall's *Sound* is a popular exposition of the subject, illustrated by well-chosen experiments. Helmholtz' *Tonempfindungen*, or *Sensations of Tone* (Eng. trans. 1875), discusses in a highly original manner the borderland between sound as a branch of physics and music as a branch of æsthetics. Sedley Taylor's *Sound and Music* (2d ed. 1883) is a simple exposition of the chief of Helmholtz' discoveries. Konig's *Expériences d'Acoustique* (1889) contains some valuable novelties. See *Nature*, vol. xliii. 1890; also the articles ACOUSTICS, HARMONICS, MICROPHONE, TELEPHONE, VOICE.

Sound (A.S. and Ger. *Sund*), the strait which leads from the Cattegat into the Baltic Sea, having Sweden on the east and the Danish island of Zealand on the west. It forms the usual passage from the North Sea to the Baltic, is 50 miles long and nearly 3 miles wide at its narrowest part, between the towns of Helsingborg and Elsinore. Its passage, defended by the strong Danish castle and fortress of Kronborg, was forced by Nelson in 1801 (see COPENHAGEN). From the 15th century all ships using this channel, except such as belonged to certain of the Hanseatic towns and one or two others in the Baltic, were charged toll for passing through. These Sound Duties were abolished on 14th March 1857 by a treaty between Denmark and the principal maritime powers. A pecuniary compensation of £3,386,260, of which Great Britain paid £1,125,206, was given to Denmark, which bound itself to maintain the lighthouses and superintend the pilotage of the Sound.

Sound, in fishes. See AIR-BLADDER.

Sounding. From the earliest times navigators have ascertained the depth of the sea in shallow waters by means of a hand-lead. This consists of a hempen rope, marked off into fathoms by worsted of different colours, to which is attached a leaden weight armed with tallow or having a valved cavity to bring up a sample of the deposit at the sea-bottom. In addition to the hand-line steamers are now often furnished with a machine to ascertain the depth while under way. This consists of a winch, wire rope, fair-lead, and a sinker provided with a glass tube, which, on being removed after a sounding, indicates by the action of sea-water on a chemical coating the hydrostatic pressure on the air in the tube and consequently the greatest depth reached by the sinker. One of the latest inventions to ascertain the depth of water while a ship is in motion is the 'submarine sentry.' This is a kind of submarine kite, which is trawled after the ship at a depth of 25 or even 40 fathoms, and as soon as the kite strikes the bottom the fact is indicated in the chart-room. Very many attempts were made to sound the deep sea before satisfactory results were obtained. Magellan during the first voyage round the world attempted to sound the open ocean in the Pacific. Not having reached bottom in 200 fathoms he naïvely concluded that he had crossed the deepest part of the ocean. Ellis in 1749 and Mulgrave in 1773 failed to sound the deep sea. Sir John Ross was more successful, for in 1818 he sounded in the Arctic seas in 1050 fathoms, bringing up a specimen of the bottom. Sir James Ross during his Antarctic expedition sounded in 2425 fathoms, and on two occasions no bottom was found with 4000 fathoms of line. There was a great uncertainty about these depths owing to there being no sure indication when the weight reached the bottom. Brooke, an officer of the United States navy, in 1854 gave a great impulse to deep-sea sounding by introducing a detaching weight, the sinker being left at the bottom, and only a small tube with a sample of the bottom being hauled up with the line. A modification of this apparatus was used during the *Challenger* expedition, 3 or 4 cwt. of iron sinkers being left at the bottom in each sounding. A sudden decrease in the rate at which the rope was running out showed when the sinkers had struck the bottom. The sounding line was ⅝ inch in circumference, and in addition to the sinkers and sounding tube there were attached to it several thermometers, a water bottle, piezometers, and other instruments. Deep-sea sounding for telegraphic purposes is now carried on by means of wire rope which was introduced by Sir William Thomson (Lord Kelvin). The friction of the wire in passing through the water is much less than that of the hemp rope. It runs out and can be hauled in much more rapidly; a smaller sinker can be used, and this often can be pulled up along with the wire. When only the depth is required a fine twine with a weight is now used in sounding in deep water, the whole being cut adrift when the depth is ascertained. The time employed in hauling in the line is thus saved, which more than repays the loss of the twine and weight.

See *Narrative of the Cruise of H.M.S. Challenger*, vol. i.; *Deep-sea Sounding and Dredging*, by Sigsbee; and *Challenger Report on Deep-sea Deposits*, by Murray and Renard.

Soup. As a general rule a soup is made by boiling meat or vegetables in what is called 'stock.' To prepare the latter the cook obtains fresh meat, bones, and vegetables such as carrots or leeks, and after the addition of salt allows them to simmer for some hours in sufficient water. The stock is the infusion thus prepared, and contains small quantities of starch, if vegetables have been used, and in any case some gelatine, which will often cause it to solidify on cooling. Together with a small quantity of nourishment, the infusion has extracted from the meat and vegetables those pleasant flavoured extractives which give it taste. Taking this stock as a basis, the various soups are made by boiling with it the bones and flesh of the hare, ox-tails, &c., and vegetables such as carrots, potatoes, turnips, rice, sago, &c.

If we view the preparation of soups from the point of domestic economy, the following facts must be kept in mind. Bones, otherwise valueless to the householder, contain much nutritive gelatine, which is extracted from them in the preparation of stock; no bones should therefore be thrown away, for their use is a clear gain. It is to be remembered that meat on the other hand yields little of its nutritive matter to the stock, and if the meat be thrown away, as it generally is in England, the greater part of its value is lost. It is the greatest waste of nutritive material to prepare a stock from gravy beef, which yields hardly more to the water than its flavouring extractives; yet householders regularly buy meat for this wasteful purpose. If then it is an object to obtain the nutritive value from the food, the meat should as much as possible be retained and eaten. While the greatest extravagances may be thus committed by using meat, which might be eaten as such, in the preparation of stocks and clear soups, it is certainly the case that equal wastefulness is frequently committed by throwing away the water in which meat, fowls, fish, bacon, and pork have been boiled. These always contain some nutritive matter, and every capable cook should be able to make it the basis of an excellent soup.

From a dietetic point of view we may regard soups as gastric stimulants and as articles of nutrition. They owe their stimulating properties to their warmth, and the salt and flavoured extracts they contain, and are of value inasmuch as they cause a ready flow of digestive juice preparatory to the more substantial portions of the repast. To some persons this stimulating action is a necessary preliminary to a properly digested meal, and it is often obtained by more harmful resorts, say to sherry and bitters. Most persons after a hard day's work, and with the bodily energies below par, have experienced the difficulty of at once facing a plate of cold mutton or beef, which would however have been quite acceptable if it had been introduced by a basin of hot broth.

From the point of view of nourishment little can be said of clear soups and beef-tea, and numberless invalids are yearly starved out of existence by doctors and nurses who imagine that by stewing a pound of gravy beef the nourishment goes to the water. Soups thickened by vegetables, such as peas, potatoes, &c., are highly nutritious, and pieces of meat and thick gravy retained in the soup add greatly to its nutritive value.

Soutane, the French for a Cassock (q.v.).

South, SIR JAMES (1785–1867), astronomer, in 1829 elected President of the Astronomical Society, and knighted the following year.

South, ROBERT, a great English preacher, was born a London merchant's son at Hackney in 1633, educated for four years under Busby at Westminster, and elected student of Christ Church, together with Locke, in 1651. Three years later he took his bachelor's degree, and that same year wrote a Latin copy of verses congratulating the Protector Cromwell on his peace with the Dutch. He took his M.A. in 1657, but not, it is said, without some opposition from Dr John Owen, then Dean of Christ Church. Next year he received orders from a deprived bishop, and was appointed in 1660 public orator to the university. During his tenure of this office occurred many striking occasions for his eloquence—the installation of Clarendon as chancellor in 1661; the burial of Juxon and the translation of Laud in July 1663; the visit of the king and queen, and the presentation of Monmouth for a degree, in September 1663; the foundation of the Sheldonian Theatre in 1664, and its formal opening in 1669. His vigorous sermons, full of sarcastic mockery of the Puritans, were delightful to the restored royalists. He became domestic chaplain to Clarendon, and further preferment followed quickly. In 1663 he was made prebendary of Westminster, canon of Christ Church in 1670, and rector of Islip in Oxfordshire in 1678. He went as chaplain with Clarendon's son, Laurence Hyde, afterwards Earl of Rochester, on his embassy to congratulate John Sobieski on mounting the throne of Poland (1677), and in December wrote from Danzig his impressions in the long and interesting *Account* sent to Pocock, the Oxford professor of Hebrew. It is supposed that South might have been a bishop if he would, and there is one story on record of his preaching in 1681 before the king on 'The lot is cast into the lap' (Prov. xvi. 33). Speaking of the strange accidents of fortune he said, 'And who, that had beheld such a bankrupt, beggarly fellow as Cromwell, first entering the parliament-house with a threadbare, torn cloak and a greasy hat (and perhaps neither of them paid for), could have suspected that in the space of so few years he should, by the murder of one king and the banishment of another, ascend the throne, be invested in the royal robes, and want nothing of the state of a king but the changing of his hat into a crown?' At these words the king fell into a violent fit of laughter, and turning to Lord Rochester, said, 'Ods fish, Lory, your chaplain must be a bishop, therefore put me in mind of him at the next death.' Unfortunately for the story, this sermon—one of those published by South himself—is inscribed as 'Preached at Westminster Abbey, February 22, 1684–85,' a fortnight after Charles's death. South appears to have thought Charles too lenient rather than too severe against religious sectaries, but during the reign of James he suppressed his disapproval of the 'Declaration of Indulgence,' although Papists were almost as hateful to him as Puritans, and it is interesting to find in three of his published sermons, preached in 1688, not a single intelligible political allusion. Yet we are told that during Monmouth's rebellion he professed himself ready, if occasion required, to exchange his black gown for a buff coat. After some hesitation South acquiesced in the Revolution, but blazed out with anger against the proposed schemes of Comprehension and Toleration which quickly came to nothing. In 1693 began his great controversy with Sherlock, Dean of St Paul's. The latter, at first a Nonjuror, had been suddenly converted to the more politic course by Bishop Overall's *Convocation Book* (written 1606, but not published till 1690), and had been rewarded by being reinstated as Master of the Temple and appointed Dean of St Paul's. To the Socinian controversy then disturbing the minds of Englishmen he had contributed *A Vindication of the Doctrine of the Trinity*, the intention to prove that there was nothing in the dogma contradictory to right reason. In his endeavour to adapt it to the more modern philosophy he unhappily employed phraseology too capable of ambiguity, and such phrases, for example, as his description of the Three Persons of the Divine Tri-unity as 'Three distinct infinite Minds or Spirits' having 'self-consciousness and mutual-consciousness,' were loudly denounced as mere Tri-theism. South flung his *Animadversions* anonymously into the fray, but the bitter irony and fierce sarcasms quickly betrayed his hand. The book showed ample learning and masterly incisiveness of logic, but too large a part was mere abuse and personal invective. Not content with demolishing Sherlock's learning, he abuses his style, his orthography, the errors of the press, and even descends so low as to sneer at him as a henpecked husband. Sherlock published a *Defence*, to which South rejoined, and still anonymously, in his no less vigorous *Tri-theism charged upon Dr Sherlock's new notion of the Trinity*. The controversy became the talk of the town, and an extant doggerel ballad, beginning 'A dean and prebendary had once a new vagary,' satirises it together with Burnet of the Charterhouse's attack upon the Pentateuch in his *Archæologia*, as having by its noise driven religion itself away the while. The king himself interposed by an injunction addressed to the archbishops and bishops to the effect that no preacher should advance views on the Trinity other than those contained in Scripture, and agreeable to the three Creeds and the Thirty-nine Articles. One of the last things recorded of South is his activity in making interest on Dr Sacheverell's behalf, and he is said to have refused the see of Rochester and deanery of Westminster on the death of Dr Sprat (1713). He survived till eighty-three, died on Sunday, 8th July 1716, and was buried in Westminster.

South's sermons are masterpieces of clear thought expressed in direct vigorous English, sometimes rising to splendid eloquence, and often seasoned with a wit and sarcasm altogether unusual in the pulpit, and sometimes far beyond the limits of propriety. A masculine intellect, a mastery of arrangement and analysis, and an uncompromising strength of conviction and of confidence in his own opinions were qualities enough to make a great preacher, but the one supreme gift of the orator, that of genuine and quickening enthusiasm, was denied him. Still more, even his noblest passages are too often marred by a bitterness and party-spirit which warped his judgment and clouded his intellect with prejudice. 'A learned but ill natured divine,' as Burnet calls him, he abhorred all mysticism and extravagance, sneers at the new philosophy and the recently founded Royal Society, and carried to a height unusual even among royalists the fatal Stuart theories of passive obedience and the divine right of kings. Yet, though South loved to be called the 'preacher of the Old Cavaliers,' he did not spare their vices, while it still remains true, as Dean Lake says, that hatred of vice is far less prominent in his preaching than hatred of Nonconformity. Yet South could rise to the height of a great argument, and such sermons as that on 'Man made in the Image of God' give him rank among the greatest masters of English eloquence. Just as on the one side his power of wrapping up in homely words the bitterest ridicule and invective recalls the stronger hand of Swift, so on the other his positiveness of mind, dialectic skill, and power of passionate indignation reminds us of the greater Bossuet.

He himself published many single sermons, and a collected edition in six volumes in 1692, which went through various editions, and was supplemented by five additional volumes in 1744. In 1717 appeared his *Posthumous Works*, with a Memoir, also his *Opera Posthuma Latina*. The foregoing were republished at the Clarendon Press, Oxford, in 7 vols. in 1823 (5 vols. 1842). A useful edition of the sermons was that published by Bohn (2 vols. 1844). See the *Quarterly Review*, vol. cxxiv. (1868), and Dean Lake in 'Classic Preachers of the English Church,' 1st series (1877).

Southampton, a municipal, parliamentary, and county borough and important seaport, in the south of Hampshire, 12½ miles SSW. of Winchester, 23¼ NW. of Portsmouth, and 79 SW. of London by the London and South-western Railway (1840). It occupies a peninsula at the head of Southampton Water, and between the estuary of the Test on the west and south and the mouth of the Itchen on the east. There are considerable remains of the 14th-century town-walls, and four out of seven gates, the Norman Bargate being much the finest, though shorn of its effigies of Sir Bevis of Hampton and the giant Ascapard. Southampton is furnished with the usual municipal and other institutions common to all thriving towns, and has besides the Watts Memorial Hall (1876), a grammar-school (1553; rebuilt and reorganised 1872-75), the Hartley Institution (1862), and the headquarters of the Ordnance Survey (1857). St Mary's Church (1878-79), by Street, is a memorial to Bishop Wilberforce. St Michael's Church, the oldest in the borough, contains Norman tower arches, and several of the private houses are of Norman architecture. The *Domus Dei*, or God's House, dates from the end of the 12th century, and is one of the earliest hospitals in England; in its chapel (now used for French service) are buried the Earl of Cambridge, Lord Scrope, and Sir Thomas Grey, executed by Henry V. for treason in 1415. The docks, first opened in 1842, can float the largest steamers, and have been greatly extended and improved. A new tidal dock, 18 acres in extent and having a minimum depth of 26 feet at low-water spring-tides, was opened by Queen Victoria on 26th July 1890; its cost was £300,000. The revenue of the Dock Company in 1890 was £111,262. Southampton is the place of departure and arrival of the West India and Brazil and the South African mail steam packets. There is considerable traffic between Southampton and the Channel Islands and French coast, and also a large cattle trade with Spain and Portugal. In 1890 the gross tonnage of the shipping was 2,139,789 tons. Yacht and ship building and engine-making are actively carried on. Incorporated as a borough by Henry I., Southampton returns two members to the House of Commons. Pop. (1801) 7913; (1851) 45,305; (1881) 60,051; (1891) 65,325.

Southampton supplanted the Roman station of *Clausentum*, which stood about one mile to the north-east, and its foundation is ascribed to the Anglo-Saxons. It is called Hamtune and Suth-Hamtun in the Saxon Chronicle, and Hantune in the Domesday Book. After the Conquest Southampton, from which there was ready transit to Normandy, began to prosper rapidly, and in early times it traded with Venice and Bayonne, Bordeaux and Rochelle, Cordova and Tunis. A great part of it was burned by the combined French, Spanish, and Genoese fleets in 1338, and in the following year its defences were strengthened. Southampton is the birthplace of Isaac Watts (to whom in 1861 a monument was erected in the West Park), of Thomas Dibdin, and of Sir J. E. Millais.

SOUTHAMPTON WATER is a fine inlet, stretching north-westward from the point at which the Solent and Spithead unite. It is 11 miles long and nearly 2 miles wide. The Isle of Wight, which intervenes between the Southampton Water and the Channel, forms a magnificent natural breakwater, and occasions a second high-water two hours after the first. Southampton Water receives the Test or Anton, Itchen, and Hamble.

See the map at the article PORTSMOUTH; J. Silvester Davies' *History of Southampton* (1883); and F. M'Fadden's *Vestiges of Old Southampton* (1891).

Southampton, HENRY WRIOTHESLEY, EARL OF (1573-1624), the friend and patron of Shakespeare (q.v., p. 364), was mixed up with Essex's insurrection, took part in the colonisation of Virginia, was imprisoned in 1621 for opposition to the court in parliament, and died of fever at Bergen-op-Zoom whilst fighting for the Dutch.

South Australia has Western Australia on one side and Queensland, New South Wales, and Victoria on the other. Originally it lay between 132° and 141° E. long., extending only to 26° S. lat. Inclusive of the Northern Territory, it now crosses the continent between 129° and 141° E., being 1850 miles in length. The present area is 903,690 sq. m. (of which the Northern Territory contains 523,620), or more than fifteen times the size of England and Wales. Less barren than Western Australia, it has not the fertility of the eastern colonies, from want of sufficient rain. Two dry peninsulas, Yorke and Lincoln, or Eyria, point southward, enclosing two great inlets—Spencer's Gulf and Gulf St Vincent. Kangaroo Island lies between. A chain of mountains runs from the south-east up to the Lake District depression. Ranges, with outliers, are seen right across to, and through, the Northern Territory; but few points rise to 3000 feet: Lofty, near Adelaide, is 2300 feet. The Murray River of eastern Australia has its mouth in South Australia. Torrens, by Adelaide, and a few other short streams reach the

sea. Macarthur, Roper, Victoria, and Liverpool enter the Indian Ocean. Salt lakes, as Torrens, Gairdner, and Eyre, are inland; Victoria, Albert, and the Coorong are near the Murray outlet. Adelaide, the capital, is in 34° S. lat. The ports are Glenelg, Adelaide, Wakefield of St Vincent's Gulf, Lincoln, Pirie, Augusta of Spencer's Gulf, Macdonnell in the south east. The area of settlement is mainly in the south-east corner of the colony.

History.—The north coast was clearly laid down in charts of the 16th century—even as soon as 1542, the primary discovery being due to the Spaniards or Portuguese. The Dutch ship *Gulde Zeepard*, 1627, sailed along the south coast, eastward of Cape Leeuwin, as far as the western border of South Australia. Flinders made known in 1802 the two great gulfs and Kangaroo Island, meeting the French explorer Baudin in Encounter Bay. Grant, in the *Lady Nelson*, 1800, sighted land to the south-east. The settlement of the region was proposed by a private company in 1831, and in 1835 a grant of land was made to the South Australian Association. The first party landed on Kangaroo Island, July 1836, and possession of the country was taken on the Adelaide Plains, December 28th. In 1841 South Australia became a Crown colony. After the usual colonial fluctuations of fortune, progress was established by the Burra Burra copper-mine (see Vol. I. p. 588), and the cultivation of large areas of corn.

Geology.—South Australia is undeniably of more recent formation, as a whole, than eastern or Western Australia. It is comparatively deficient in both flora and fauna, and has a larger surface of later formed rocks. Several ancient formations have few or no fossils to indicate their age, though Lower Silurian beds are recognised as decidedly fossiliferous. Mountain-ranges illustrate the primary rocks, and show traces of a Cambrian period. The rise from Cape Jervis to the Lake District appears older than that more northward, which may be Devonian. Metamorphisms are abundantly exhibited, and both granite and basalt occur frequently as intruding veins, as well as in mountain masses. Silurian beds are declared 30,000 feet thick; granite over extensive areas is detected westward and northward; Palæozoic slates of superior quality are of commercial value. Mining for metals is conducted in these older rocks. The Secondary or Mesozoic beds are not so common, though Jurassic ones are crossed in the interior. The Cretaceous development rests on the upturned edges of earlier and disturbed strata. The Tertiary rocks are of great extent and considerable variety. The upper reaches of the Murray River are marked by Miocene, a formation conspicuous in other localities under the appellation of *Desert Sandstone*, the disintegration of which furnishes the material for far-sweeping sands. In parallel and yet shifting sand-dunes they proved a trial to early explorers. Sand drifts, the debris of Pliocene beds, have swept over what had been fertile tracts and increased the aridity. The Lower Murray has dug its way through hundreds of miles of limestone bearing marine fossils. The land is poor where the arenaceous quality predominates, but fertile where the calcareous is near the surface. As coralline limestone one observes the banks of the great sea-lake Coorong. Farther to the south-east, near the Victorian border, lies the charming and productive Mount Gambier district, with its extinct craters, subterranean rivers, native wells, stalactitic caverns, and luxuriant vegetation. Lava and volcanic ash walls rise through the Tertiary limestone to form the Devil's Punchbowl or the Devil's Inkstand. Around the hollowed cone of Mount Schank are bands of flint in the limestone. Singular soda-springs occur in the recent beds of the interior, with silt around the basins. Pleistocene strata cover a large area, but are not of great depth. The Mount Gambier discharges of lava and ash belong to that period. Extensive remains of the gigantic herbivorous Diprotodon bear witness to different meteorological conditions; the drying up of inland waters must have caused its destruction. Evidences exist of glacial action at another age. During this century a decided rise of part of the southern coast-line has been observed.

The *climate* over so extensive an area as that of a third of Europe cannot but be varied, though no other Australian colony has so much uniformity of weather. Generally speaking, it is both dry and warm. The great mass of land is so compact, and so little relieved by lofty hills or dense forests, that climatic conditions are pretty similar. Travellers in the central desert complain of piercing cold, even to ice formation, in the early hours, though followed after sunrise by a temperature of from 80° to 100° in the shade. Contiguity to the coast gives a night sea-breeze. A thermometer of 175° in the sun and 135° in the shade can hardly be exceeded elsewhere. Adelaide itself, in 34° S., has known 120° in the shade; its winter is superior to the Riviera or Algiers in uniform mildness and absence of frost. The north hot wind, so trying to the weak, seems to come from about lat. 26°. On Black Thursday, of 1850, the scorching winds caused terrible destruction. Dust storms accompany the blast, and add to the discomfort; but they introduce grateful showers. On the northern coast the deposition is effected by the monsoon, whose influence more or less extends even to lat. 28° S. Thus during the short rainy season the northern shore may have three to four times the fall experienced in Adelaide. The Great Austral Plains know but few and slight showers, with excessive evaporation. Yet, though the grass fails under the dryness, abundant shrubs give sustenance to live-stock. North of Goyder's Line it is of little use to attempt farming; still artesian wells can draw a constant supply from subterranean flowing streams. Droughts are often produced by the failure of the monsoon to come southerly enough, and they lower the bushels of corn per acre even to five only. While the north coast at Port Darwin received 60 to 70 inches of rain in the year, Mount Lofty had 40, Gambier 30, Mount Barker 29, Port Lincoln 19, Adelaide 20, Blanchetown 12, Port Augusta 9 (but 2 in 1859). Cyclones are very rare. The Adelaide climate is thus averaged: temperature from 34° to 113°; barometer, 30·53 to 29·09; wet-bulb, 55°. Barometer rises when the wind is from NW. by S. to SE., the highest; falling by N. to NW., lowest. The effect of climate on health is generally most favourable; though the summers are trying to infants, they do not hinder field labour for Europeans. Many consumptives have gained strength in South Australia.

Fauna.—Marsupial animals predominate—the kangaroo, jerboa, wallaby, native cat or Dasyurus, Phascogale or brush-tails, Myrmecobius or ant-eater, Perameles or bandicoot, Hapalotis or marsupial rat, Hydromys or beaver rat, Hypsiprymnorus or kangaroo rat, Phalanger or flying-opossum, Phascolarctos or koala, Echidna or porcupine, Ornithorhynchus, bats, &c. Among 700 birds are the eagle, hawk, owl, king-fisher, swallow, finch, thrush, robin, diamond-bird, honey-bird, crow, cuckoo, parrot, cockatoo, quail, ibis, heron, black swan, and penguin. Insects are not wanting. Of fish there are 42 peculiar genera. Whales and seals were once numerous around the southern coast.

Flora.—The colony is not so rich in vegetable forms as either of its neighbours. It has but 5 of

19 Australian casuarinas, 70 of 300 acacias, and 30 of 130 eucalypts. In the Northern Territory are many Indian forms. Xanthorrhææ or grass-trees are seen on poor soil, and stunted shrubs on arid wastes. With few native trees in the country, government has established forest reserves and forest nurseries. The mulberry is cultivated for silkworms. Pines are numerous in some parts.

The *pastoral* resources can hardly compare with those of the eastern colonies of Australia, owing to greater dryness of climate. While live-stock may be found on farms in the more settled districts, the larger flocks and herds are upon the leasehold squatting *runs* outside the area of cultivation. The four pastoral districts contain 313,000 sq. m.

Agriculture has received great attention. In spite of frequent droughts bread-stuffs head the export list. The first land sales were in farming areas of 80 acres each, which led to cultivation rather than to pasturage; the land devoted to the growth of crops was recently 2,864,877 acres. Successive land acts have increased facility for the acquisition of the soil. Though cereals occupy most ground, potatoes are readily raised in the moister south-eastern quarter, and vines are of successful culture. In favourable seasons the drier interior can furnish good wheat. Railways, 1700 miles long, afford assistance to the farmer; and good roads extend nearly 5000 miles. The Northern Territory, being mostly tropical, has a fine future before it for the growth of rice, spice, and sugar, when suitable coloured labour can be procured. Though much of the interior is leased for pasturage, the state has only sold 9 million acres out of 569 millions. German settlers introduced the vine industry. The conversion of grapes into currants and raisins provides a fresh article of export. Olives and fruits are raised in abundance, and Adelaide now ships apples to London.

Mining.—The first lead-mine was opened in 1841; the first copper at Kapunda, 1843; the first gold at Montacute, 1846. The copper Burra Burra began in 1845, Wallaroo and Moonta in 1861. Copper is found along ranges for hundreds of miles. Tin, bismuth, and precious stones have been obtained. Gold workings exist in several places, but the best are in Northern Territory. The Barrier silver-mines are just over the New South Wales border. There are no coal beds. Excellent quarries exist of granite, marble, and slate. Mineral lands are leased from government. The high price of labour and cost of carriage hinder the working of mines that yet have a rich percentage of ores.

Population.—In 1891 there were 340,000 white inhabitants, and 5000 aborigines. Of places of worship the Wesleyans had 46,415 sittings; Roman Catholics, 44,138; Church of England, 22,250; Bible Christians, 19,260; Primitive Methodists, 16,144; Independents, 14,960; Baptists, 13,525; Lutherans, 11,000; Presbyterians, 6600. The public day schools were 550, with 1067 teachers; the private schools, 262 teachers. State education is free. The university was established in 1872.

The *government* is similar to that of other Australian colonies. The governor is appointed by the crown. There are 30,000 voters for members of the legislative council or upper house, and 60,000 of the assembly or lower house. The Constitution Act was passed in 1856. The revenue for 1890 was £2,557,771, the expenditure £2,579,257. The customs department brought in £675,085 from duties, and £4522 from excise. For purposes of local government there are 33 municipalities and 140 district councils. The public debt, £21,657,000 in 1891, was incurred for improvements, the outlay on railways taking more than half, and other public works eight millions.

The larger amount of the *commerce* is with other Australian settlements. While the total imports for 1890 came to £8,262,673, those from Great Britain were only £2,483,416; but of £8,827,387 exports the mother-country took £4,296,647. The exports of colonial produce included wool, £1,353,762; wheat, £1,382,418; flour, £613,823; live-stock, £60,735; skins and hides, £174,137; bark, £56,000; tallow, £16,951; wine, £50,738 (762,776 gallons); gold, £20,808; copper, £155,417; copper ore, £71,575. But the exports included importations of silver-lead from the New South Wales side, £1,822,826, and ore £736,282. The exports to the Barrier district were £1,186,149. The Northern Territory imported £114,135, and exported £155,008. The tariff is protectionist: the *ad valorem* duty, 5, 10, 15, 20, and 25 per cent., produced £233,723 of the customs' £615,266 in 1891. During 1890 there entered 1041 vessels of 1,075,133 tons, and cleared 1081 vessels of 1,115,309 tons. The banks at the beginning of 1891 showed average liabilities of £7,759,926, and assets of £11,489,842. There were 609 post-offices, and 182 money-order offices. The telegraph and telephone lines were 5623 miles in length; one line runs north from Adelaide 700 miles. Northern Port Darwin is connected by the electric line with the extreme south ports.

See, besides South Australian government handbooks and Australian handbooks generally, Harcus' *South Australia* (1876); Newland, *The Far North Country* (Adelaide, 1887); Dutton's *South Australia and its Mines*; the present writer's *Climate and Health in South Australia*, and *Resources of South Australia*; Finniss' *Constitutional History, 1836–57* (Melbourne, 1889); also Gill's *Bibliography of South Australia* (Adelaide, 1888), and Hodder's *Life of G. F. Angas* (1891).

South Bend, capital of St Joseph county, Indiana, on the St Joseph River (navigable for small steamers), 86 miles by rail ESE. of Chicago. It contains a Roman Catholic university and academies, and has large manufactories of wagons, agricultural implements, furniture, woollens, paper, flour, &c. Pop. (1880) 13,280; (1890) 21,819.

South Bethlehem. See BETHLEHEM.

Southbridge, a town of Massachusetts, on the Quinebaug River, 70 miles by rail SW. of Boston, with manufactories of cottons, woollens, knives, boots, &c. Pop. (1890) 7744.

South Carolina, one of the original states of the American Union, with an area of 30,570 sq. m., including 400 sq. m. of water-surface, is nearly triangular in outline, and is bounded on the N. and NE. by North Carolina, SE. by the Atlantic Ocean, and SW. by Georgia. Numerous islands near the southern part of the coast are separated from the mainland and from each other by shallow sounds and inlets. For 100 miles inland the land is generally low and level, much of it still covered with pine forests (*Pinus palustris*). West of this alluvial plain is a range of undulating sandhills about 60 miles in width. This 'middle country' was long the least fertile part of the state. Farther west the 'ridge-country' rises, generally abruptly, from the Savannah to the Broad River on the north, presenting a region of rare beauty and fertility. The average elevation of the western third of the state is nearly 2000 feet above the sea-level. Mount Pinnacle, Cæsar's Head, and Table Mountain, belonging to the Blue Ridge range, in the north-west part of the state, rise to the height of about 4000 feet. Geologically the eastern part of the state is quaternary or alluvial and the western is eozoic, with extensive tertiary and older formations intermediate. Most of the rivers—the largest the Santee (q.v.)—are navigable by steamboats nearly to the foot-slope of the ridge region, where they supply abundant water-power. South Carolina

Company.

has three customs districts, with ports of entry at Georgetown, Charleston, and Beaufort.

The state is rich in mineral products, which recent enterprise is profitably developing. The gold-belt extends from the North Carolina line in a south-westerly direction, the most productive mines being in York, Lancaster, Chesterfield, and Spartanburg counties. Granite is abundant in Abbeville, Fairfield, and Newberry counties; and itacolumite, a flexible sandstone, is quarried for grindstones in Spartanburg. Kaolin of superior quality, and used for artificial teeth, is obtained in Chester county. Pliocene marl is abundant in Horry, Sumpter, and Marlborough counties. Post-pliocene is found in Edisto Island and near the Savannah, Santee, Ashley, and Cooper rivers. But the most important mineral product of South Carolina is its famous deposit of phosphate rock, extending about 70 miles from the mouth of the Broad River near Port Royal to the head-waters of the Wando, north of Charleston. Its direction is parallel with the coast, and its width in some places is 30 miles. It crops out near the Ashley River, where it was first observed. This immense phosphate bed is generally covered with quaternary clays and sands, and its nodular phosphatic layer rests upon deep strata of calcareous marl, beneath which cretaceous marls extend along the entire eastern part of the state. In 1892 about twenty companies found profitable investment for more than $4,000,000 capital in the mining and manufacture of nearly 4,000,000 tons of phosphate rock. It is obtained as a tribasic phosphate, and is used mainly in the manufacture of superphosphates. The average of lime phosphate is from 52 to 60 per cent. of the rock. Gray iron ore (magnetite) is found in Union, York, and Spartanburg counties; and copper pyrites (chalco-pyrite), galena, limonite, malachite, pyrolusite, and pyromorphite or phosphate of lead have been found in the western part of the state, and sand for glass in Aiken and Barnwell counties. Deer, wild turkeys, raccoons, foxes, squirrels, and other small game are still numerous in the forests; and the rivers, sounds, and inlets are stocked with a great variety of fish. Alligators of large size inhabit the tidal rivers.

South Carolina, called the Palmetto State from the growth of the cabbage-tree (*Sabal palmetto*) near the coast, ranks twenty-third in the list of forty-four states. By the census of 1890 the population was 1,151,149, consisting of 692,503 coloured persons, 458,454 white, 172 Indians, and 20 Chinese. Of the thirty-five counties (districts previous to 1868) Newberry alone failed to show increase from 1880 to 1890. Charleston, the largest city, had a population of 54,955 in 1890, and Columbia, the capital, 15,353. The mild climate is salubrious except in the rice-lands. The low islands along the coast afford desirable summer-resorts, as well as the western mountain-region known as 'the land of the sky.' The average rainfall in the eastern part is from 42 to 44 inches. The coast lies within the usual limits of West India cyclones, which are often destructive of life and property. The damage caused by the cyclone of 1885 exceeded $1,500,000 in Charleston alone. On the night of August 31, 1886, Charleston was nearly destroyed by an earthquake, which caused directly twenty-seven deaths, and destroyed property to the amount of over $6,000,000.

The earliest attempt at settlement by Europeans within the limits of the state was in 1562 by John Ribault at the head of a party of French Protestants sent over by Admiral Coligny. They built a fort on an island in the harbour of Port Royal, and named it *Arx Carolina*, in honour of the king Charles IX. The twenty-six colonists left by Ribault soon abandoned the fort to return to France. In 1630 Sir Robert Heath obtained a grant from Charles I. reaching from latitude 36° to the Gulf of Mexico, but failure to colonise forfeited the title. In this grant the territory was named Carolana for Charles I. In 1662 Charles II. granted to Lord Clarendon and seven associates all the territory from the Atlantic to the Pacific lying between parallels 31° and 36° N. Two years later the northern boundary was made 36° 30′. In 1670 three ship-loads of English settlers under William Sayle landed at or near Port Royal, but the next year moved to the right bank of Ashley River. In 1680 they moved again to the present site of Charleston. The proprietary government under the 'model Constitution,' drawn up by John Locke (see NORTH CAROLINA), lasted till 1729, when George II. bought out the proprietors and divided Carolina into two royal provinces. Subsequently South Carolina became one of the most flourishing of the British colonies and attracted an intelligent and enterprising class of settlers from Europe, including many French Huguenots, who came soon after the revocation of the edict of Nantes in 1685. Hence the Gallic origin of so many distinguished names in the history of the state.

Sir John Yeamans, who had been appointed governor, brought from Barbadoes two hundred negro slaves in 1671. The blacks in a few years nearly equalled the whites, and since 1820 have been more numerous in the state. During the revolutionary war South Carolina furnished her full quota of men and means, and suffered much from British invasion and occupation. This state was the first to ratify the Articles of Confederation, February 5, 1788, and the eighth to ratify the constitution, May 23, 1788. In 1833 a convention called by the legislature passed the ordinance known as the Nullification Act (q.v.). South Carolina was the first state to secede from the Union. A convention called by the legislature met on the 17th December 1860, and passed an ordinance of secession by a unanimous vote on the 20th. Six sister slave-states soon followed the example of South Carolina, and formed the Southern Confederacy, which was subsequently increased by four more. South Carolina was re-admitted into the Union on June 25, 1865. Since the accomplishment of reconstruction the state has attained a high degree of prosperity. It sends seven representatives to the national congress. The excellent public school system affords good educational advantages to pupils of both races in primary and intermediate studies; and provision is made for higher education of both races, and for instruction in agricultural and other industrial departments. The number of pupils enrolled in the public schools in 1890 was 203,461, the total expenditure $460,260.

South Chester. See CHESTER.

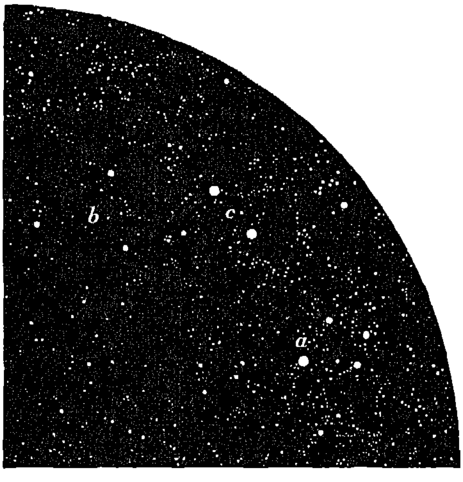
Southcott, JOANNA, a more than usually strange specimen of the religious visionary, was born in Devonshire, of humble parentage, about 1750. In youth a domestic servant at Exeter, she joined the Methodists, and learned the art of prophecy from one Sanderson. About 1792 she declared herself to be the woman driven into the wilderness of Rev. xii., and boldly gave forth predictions in prose and verse. She soon came to London on the invitation of Sharp the engraver, and here she published *A Warning*, &c. (1803), *The Book of Wonders* (1813–14), and *Prophecies concerning the Birth of the Prince of Peace* (1814). She also issued 6400 sealed papers to her followers, which she termed her *seals*, and which ensured salvation; their cost was from a guinea to twelve shillings. Strange to say, otherwise intelligent men believed in her. At length she imagined herself to be pregnant, and announced that she was to give birth, at midnight on the 19th October 1814, to a second Shiloh or Prince of Peace. Her followers received this announcement with devout reverence, and prepared an expensive cradle for the occasion. But she merely fell into a trance, and on 27th December 1814 she died. It was found that the appearance of pregnancy which had deceived others, and perhaps herself, was due to dropsy. Her followers continued to believe that she would rise again from her trance. In 1851 they still numbered over 200, with four places of worship, and were not quite extinct in 1887.

South Dakota, one of the two states constructed in 1890 out of the former territory of Dakota (q.v.).

South Easton, a borough of Pennsylvania, at the mouth of the Lehigh River, opposite Easton, with manufactures of cottons, wire, &c. Pop. 5616.

Southend, an Essex watering-place, at the mouth of the Thames estuary, 42 miles E. of London. Dating from a visit here of Queen Caroline and the Princess Charlotte in 1804, it was in great part built by Sir S. Morton Peto (1809–89), and has good level sands, a public hall (1872), and a new pier, over a mile in length, undertaken in 1888, and costing, with tramway and concert-room, some £60,000. Pop. (1851) 2462; (1871) 4561; (1881) 7979; (1891) 12,333.

Southern Cross, one of the star groups in the southern hemisphere of the heavens. It lies in right ascension 12 hours, and dec. 60° S., being thus a considerable distance from the south pole of the heavens. It was added to the list of constellations by Royer in 1679. The four principal stars form a rough cross when seen above the pole. The figure is of considerable size, being about 6° of dec. in height.



Quadrant of the Southern Heavens from the Pole to the fortieth degree, showing the Southern Cross, *a*, and the Triangle, *b*. The two bright stars at *c* are α and β of Centauri.

Southerne, Thomas, dramatist, known as 'honest Tom Southerne' in the world of his day, was born at Oxmantown in County Dublin in 1660 or 1661, studied at Trinity College, Dublin, and entered at the Middle Temple, London, but in 1682 began his career as playwright with a compliment to the Duke of York in *The Loyal Brother, or the Persian Prince.* Dryden wrote the prologue and epilogue, raising his fee on the occasion, and Southerne had the honour of finishing Dryden's *Cleomenes, or the Spartan Hero* (1692). Southerne served a short time under the Duke of Berwick, and at his request wrote the *Spartan Dame,* receiving £120 for the copyright. His best plays, both tragedies, were produced in the reign of William III.—*The Fatal Marriage* (1694), and *Oroonoko,* (1696) based on Afra Behn's novel. His comedies are thin, and hardly more decent than the rest in that day. Southerne contrived to thrive in his vocation, and is pleasantly described as a venerable old gentleman, regular in attendance on evening prayers, always neat and decently dressed, commonly in black with his silver sword and silver locks. Pope describes his friend as him whom Heaven sent down to raise the price of prologues and of plays. He died May 26, 1746.

Southernwood (*Artemisia abrotanum*), a shrubby species of Artemisia (see Wormwood), found wild in south Europe, and cultivated in old-fashioned gardens for its pleasant aromatic odour.

Southey, Robert, poet-laureate, was born at Bristol on 12th August 1774. His father, Robert Southey (1745–92), was an unlucky linen-draper; his mother, Margaret Hill (1752–1802), who likewise came of good old yeoman ancestry, was a bright, sweet-tempered woman, who could whistle like a blackbird. Much of his lonely childhood was passed with her half-sister, Miss Tyler (1739–1821), a rich, genteel old maid who hated noise and matrimony, and had a passion for cleanliness and the drama. With her he saw many plays; read Shakespeare and Beaumont and Fletcher, Hoole's *Tasso* and *Ariosto,* the *Faerie Queene,* Pope's *Homer,* and Sidney's *Arcadia;* and himself scribbled thousands of verses. He had meanwhile had four schoolmasters, and in 1788 was placed by an uncle, the Rev. Herbert Hill, at Westminster. There Picart's *Religious Ceremonies* led him 'to conceive a design of rendering every mythology the basis of a narrative poem;' there he formed lifelong friendships with C. W. W. Wynn and Grosvenor Bedford; and thence in 1792 he was expelled for writing an article against flogging in a school magazine. Next year, however, he entered Balliol College with a view to his taking orders. He went up to Oxford a republican, his head full of Rousseau and 'Werther,' his religious principles shaken by Gibbon; and he left it in 1794 a Unitarian, having learnt a little swimming and a little boating, and ingrained his very heart with Epictetus. And at Oxford he had a visit from Coleridge, who infected him with his dream of a 'Pantisocracy' on the banks of the Susquehanna. The Pantisocrats required wives; and wives were forthcoming in three Miss Frickers of Bristol. The eldest, Sara, fell to Coleridge; the second, Edith, to Southey; and Mary, the third, to a Robert Lovel, who with Southey in 1794 published a booklet of poems, and died two years afterwards penniless. The Pantisocrats furthermore required money, and money was not forthcoming; so, having tried medicine, and been sickened by the dissecting-room, having been turned out of doors by his indignant aunt, having lectured with some success, and having on 14th November 1795 secretly married his Edith, Southey started the same day on a six months' visit to Lisbon, where his uncle was chaplain to the British factory, and where he laid the foundation of his profound knowledge of the literatures and history of the Peninsula. He returned to England to take up law, but reading Coke to him was 'threshing straw;' so after sundry migrations—Westbury near Bristol, Burton near Christchurch, Lisbon again for a twelvemonth (1800–1), and Ireland (a brief secretaryship to its Chancellor of the Exchequer), with intervals of London—in September 1803 he settled at Greta Hall, Keswick, in the Lake Country. The Coleridges were there already, and thither came Mrs Lovel: three households were to rest on Southey's shoulders.

His school friend Wynn allowed him £160 a year from 1796 till 1807, when a government pension of a like amount was granted him (he was turning meanwhile a Tory), and on this he devoted himself to a life of strenuous, incessant authorship. *Joan of Arc* had already appeared in 1795, and *Thalaba* in 1801; there followed *Madoc* (1805), *The Curse of Kehama* (1810), *Roderick* (1814), *History of Brazil* (1810-19), Lives of Nelson (1813), Wesley (1820), and Bunyan (1830), *A Vision of Judgment* (1821), *Book of the Church* (1824), *History of the Peninsular War* (1823-32), *Colloquies on Society* (1829), *Naval History* (1833-40), and *The Doctor* (1834-47), in which comes the nursery classic of 'The Three Bears.' His works number nearly fifty, and fill more than a hundred volumes; and to them must be added his contributions to the periodicals—to the *Quarterly* alone ninety-three articles (1808-38). These paid him handsomely, so that he died worth £12,000; but the *History of Brazil* brought him in eight years only the price of one article, and *Madoc* in a twelvemonth only £3, 17s. 1d.—*Madoc*, which Scott read and thrice re-read, and which Southey himself with naive vanity admitted to be 'the best English poem since *Paradise Lost*.' His life was a busy and happy one: at forty-six he could say, 'I have lived in the sunshine, and am still looking forward with hope.' It flowed quietly on, the chief events in it his visit to Scott and Scotland (1805), his first meeting with Landor (1808), the visits from Shelley and Ticknor (1811, 1819), his appointment to the laureateship (1813), the death of his first boy Herbert (1806-16), the surreptitious publication of his revolutionary drama *Wat Tyler* (1817; written 1794), little tours in Belgium (1815), Switzerland (1817), Holland (1825, 1826), and France (1838), an honorary D.C.L. of Oxford (1820), his return as M.P. for Downton (unsolicited and declined, 1826), and Peel's offer of a baronetcy, with the welcome addition of £300 a year to his pension (1835). It came at a time of sorrow, for his wife, who had 'for forty years been the life of his life,' had six months before been placed in an asylum, and though she was brought back to Keswick, she was brought back only to die (1837). Southey never held up after that, though in 1839 he married the poetess Caroline Anne Bowles (1787-1854), for twenty years his friend and correspondent, and returned with her to Greta Hall, intending resolutely to set about two great works which he had long had in contemplation—a History of Portugal and a History of the Monastic Orders. It was not to be, for Wordsworth in 1840 found him vacuous, listless in his noble library, the 14,000 books he had collected, 'patting them with both hands affectionately like a child.' The end came on 21st March 1843; he is buried in Crosthwaite churchyard.

Macaulay in 1830 expressed a doubt whether 'fifty years hence Mr Southey's poems will be read;' the doubt has been amply justified. No poet probably so well known by name is so little known by his poetry. There are some short exceptions of course—the 'Holly Bush,' 'Battle of Blenheim,' 'Stanzas written in my Library,' half-a-dozen more. But the 'Simorg,' the 'Glendoveers,' 'Mohareb'—how many can localise these creations of Southey's muse? His epics repel, not so much by prolixity or by their irregular, sometimes rhymeless metres, as by the unreality of their fact and fancy. They remind us of scene-paintings; and a scene-painting even by Roberts will fetch just nothing in the auction-room. With Southey's prose it is otherwise. He wrote out of the fullness of knowledge, for something more than the mere sake of writing; and his was that rarest gift of good pure English. Yet even here he wrote far too much, and he was often unhappy in his choice of subjects. One book alone by him, the *Life of Nelson*, belongs to universal literature. But though there have been better poets than Southey, no poet has been a better man than he.

His *Life and Correspondence* (6 vols. 1849-50), by his younger son, the Rev. Cuthbert Southey (1819-89), contains a delightful fragment of autobiography, written in 1820-25, but coming down only to 1789. It also gives hundreds of his letters to Cottle (q.v.), Landor, Lamb, William Taylor, Rickman, Ebenezer Elliott, Kirke White, Bernard Barton, Charlotte Brontë, Crabb Robinson, Sir Henry Taylor, &c. A *Selection* from these was edited by his son-in-law, the Rev. J. W. Warter (4 vols. 1856), who also issued Southey's *Commonplace Book* (4 vols. 1849-51); his *Correspondence with Caroline Bowles* has been edited by Professor Dowden (Dublin, 1881). See, too, the latter's *Southey* ('English Men of Letters' series, 1880); Dennis' *Southey: Story of his Life* (Boston, 1887); Sir Henry Taylor's essay in Ward's *English Poets* (vol. iv., 2d. ed., 1883); the brief memoir by Sidney R. Thompson in the 'Canterbury Poets' series (1888); and Smiles's work on John Murray (1891).

South Georgia, a group of islands, uninhabited, and almost perpetually ice-bound, in 54° 30′ S. lat. and 36°—38° W. long., nearly 800 miles E. by S. of the Falkland Isles, of which they are a dependency. Area, 1000 sq. m. Discovered in 1675, they were taken possession of by Captain Cook in 1775; and here in 1882-83 lived the German expedition for observing the transit of Venus.

South Island, the southern of the two large islands which, with the small Stewart's Island, form the British colony of New Zealand (q.v.).

South Molton, a municipal borough (1590) of Devonshire, on the Mole, 10 miles ESE. of Barnstaple. It has a fine Perpendicular church (restored 1865), a market-house (1864), and some manufactures of woollens. Pop. (1891) 3126.

Southport, a watering-place of Lancashire, at the mouth of the Ribble estuary, 18 miles N. of Liverpool, 37 WNW. of Manchester, and 19 S. by W. of Preston. The first house was a wooden inn built from a wreck here in 1792, on what then was a sandy waste; and since about 1830 the place has grown more and more popular, enjoying as it does a mild climate, and having broad level sands. The esplanade (3 miles long) commands views of the Welsh and Cumberland mountains, and from it projects a pier (1465 yards) constructed in 1859-68 at a cost of £25,000, with a steam tramway running along it. Other features of Southport, with date and cost, are the Pavilion and Winter Gardens (1874; £140,000), comprising a theatre, concert-hall, aquaria, &c.; opera-house (1891; seating 2000); the Cambridge Hall (1874; £25,000), with a clock-tower 127 feet high; the Victoria Baths (1871; £45,000); the Atkinson Public Library and Art Gallery (1878; nearly £15,000); the Grecian town-hall (1853); the market-hall (1881; £40,000); the Victoria Schools of Science and Art (1887); the convalescent hospital (founded 1806; present building 1854-87); the Hesketh Public Park of 30 acres (1868); and a marine park and lake (1887; £13,000) on the foreshore fronting the town. Nathaniel Hawthorne, then United States consul at Liverpool, describes Southport as it was in 1856 in vol. iii. of his *English Notebooks* (1870). It was made a municipal borough in 1867, the boundary being extended in 1875. Pop. (1851) 4765; (1871) 18,085; (1881) 32,206; (1891) 43,026.

Southsea, a south-eastern suburb of Portsmouth, is a fashionable watering-place of recent growth, with two piers, a fine esplanade 2 miles long, a canoe lake, a common, a modernised castle of 1540, and other fortifications, barracks, &c.

South Sea Scheme (or BUBBLE) was originated by Harley (q.v.), Earl of Oxford, in 1711, with the view of restoring public credit and providing for the extinction of the floating national debt, which at that time amounted to £10,000,000. This debt was taken up by a number of eminent merchants, to whom the government agreed to guarantee for a certain period the annual payment of £600,000 (being 6 per cent. interest), a sum which was to be obtained by rendering permanent a number of import duties. The monopoly of the trade to the South Seas was also secured to these merchants, who were accordingly incorporated as the 'South Sea Company,' and at once rose to a high position in the mercantile world. The extravagant ideas then current respecting the riches of the South American continent were carefully fostered by the Company, who also spread the belief that Spain was prepared to admit them to a share of its South American trade. In 1717 the Company advanced to government other 5 millions. Their shares nevertheless rose day by day; and even when the outbreak of war with Spain in 1718 deprived the most sanguine of the slightest hope of sharing in the treasures of the South Seas, the Company continued to flourish. Far from being alarmed at the expected failure of the Mississippi Scheme (q.v.), the South Sea Company believed sincerely in the feasibility of Law's scheme, and resolved to avoid what they considered as his errors. In the spring of 1720 they proposed to take upon themselves practically the whole national debt (at that time upwards of 30 millions), on being guaranteed 5 per cent. per annum for 7½ years, at the end of which time the debt might be redeemed if the government chose, and the interest reduced to 4 per cent. The directors of the Bank of England, jealous of the prospective benefit and influence which would thus accrue to the South Sea Company, submitted to government a counter-proposal; but the more dazzling nature of their rivals' offer, in spite of protest from Walpole and other long-headed leaders, secured its acceptance by parliament. During the passing of their bill the Company's stock rose steadily to 330 on April 7, falling to 290 on the following day.

Up till this date the scheme had been honestly promoted; but now, seeing before them the prospect of speedily amassing abundant wealth, the directors seem to have thrown aside all scruples and made use of every effective means at their command for keeping up the factitious value of the stock. Their zealous endeavours were crowned with success; the £100 shares were quoted at 550 on May 28, and 890 on June 1. A mania of gambling seized the nation; preposterous companies of all kinds were floated, some of which were even prosecuted by the South Sea Company (under the 'Bubble Act') and exposed as swindling schemes. A general impression having by this time gained ground that the Company's stock had reached its maximum, so many holders rushed to realise that the price fell to 640 on June 3. Thereupon the directors sent agents to buy up eagerly; and on the evening of June 3, 750 was the quoted price. This and similar artifices were employed as required, and had the effect of ultimately raising the shares to 1000 in the beginning of August, when the chairman of the Company and some of the principal directors sold out. On this becoming known a wide-spread uneasiness seized the holders of stock, every one was eager to part with his shares, and on September 12 they fell to 400. The consternation of those who had been either unwilling or unable to part with their scrip was now extreme; many capitalists absconded, either to avoid ruinous bankruptcy or to secure their ill-gotten gains, and the government became seriously alarmed at the excited state of public feeling. Vain attempts were made to prevail on the Bank to come to the rescue by circulating some millions of Company's bonds.

The country was now wound up to a most alarming pitch of excitement; the punishment of the fraudulent directors was clamorously demanded; and parliament was hastily summoned (December 8) to deliberate on the best means of mitigating this great calamity. Both Houses, however, proved to be in as impetuous a mood as the public; and, in spite of the moderate counsels of Walpole, it was resolved to punish the authors of the national distresses, though hitherto no fraudulent acts had been proved against them. An examination of the proceedings of the Company was at once commenced, with results discreditable to the management; the private property of the directors was confiscated (to the amount of upwards of 2 millions) for the benefit of those who had suffered; seven millions due to the government were remitted; various eminent persons in and about the government were openly charged with receiving direct money bribes from the Company; the Chancellor of the Exchequer, Aislabie, being found clearly guilty, was expelled from the House of Commons, and imprisoned in the Tower. The ruin wrought by the Bubble was incalculable. See the histories of Stanhope and Lecky, and Coxe's *Walpole*.

The South Sea House in Threadneedle Street was the headquarters of the South Sea Company. When the company ceased to be a trading concern its capital was converted into annuity stock; and its premises are now subdivided into numerous offices. John Lamb was a clerk in South Sea House; and his brother Charles was admitted here to learn book-keeping.

South Shetlands, a group of islands in the South Atlantic, lying on the lines of 60° S. lat. and 60° W. long., and covered ever with ice and snow.

South Shields. See SHIELDS.

Southwark, or 'The Borough,' on the Surrey side of the Thames, was annexed to the City of London (q.v.) in 1327. For its innumerable memories reference may be made to *Old Southwark and its People* (1878), by W. Rendle, or to Mr Besant's romance, *The Bell of St Paul's*.

Southwell, a town of Nottinghamshire, since 1884 a cathedral city, on the ancient Ermine Street, 7 miles W. by S. of Newark and 12 NE. of Nottingham. A church was founded here by Paulinus about 630; but the stately cruciform minster, which with its three towers resembles York on a smaller scale, is wholly of post-Conquest date, comprising Norman nave and transepts (1110), Early English choir (1250), and Early Decorated chapter-house (1300). It measures 306 feet by 123 across the transepts, and the lantern tower is 105 feet high. A collegiate church until 1841, it became in 1884 the cathedral of a new diocese including the counties of Notts and Derbyshire, and taken from Lincoln and Lichfield; and in 1888 it was reopened after restoration. Its eagle lectern originally belonged to Newstead priory, having been fished out of the lake there about 1750. In the old 'Saracen's Head' Charles I. surrendered to the Scots commissioners (1646); Byron's mother occupied Burgage Manor House (1804–7); and there are picturesque ruins of the palace of the Archbishops of York (*c.* 1360; much altered and enlarged by Wolsey). The collegiate grammar-school was refounded in Henry VIII.'s time; and there are a literary institute and free library. Pop. (1851) 3516; (1881) 2866; (1891) 2831.

See works by Rastall (1787, 1801), Shilton (1818), Dimock (1884), Livett (1883), and Leach (1890).

Southwell, Robert, poet and Jesuit martyr, was born about 1562, son of Richard Southwell of Horsham St Faith's in Norfolk, the family being ancient and now represented collaterally by Viscount Southwell. He was stolen from his cradle by a Gypsy woman, but soon recovered, and at fifteen was sent to Paris for his education. Challoner states that he studied also at Douay, but certain it is that he soon went to Rome, being received into the Society of Jesus on the festival of St Luke 1578. After a residence at Tournay he returned to Rome and distinguished himself so highly in the course of philosophy and theology as to be appointed prefect of the English college there. He was ordained priest in 1584, and three years later arrived in England in company with Father Henry Garnet, who was also to earn the martyr's crown. Southwell was first sheltered by Lord Vaux, and next became domestic chaplain to the Countess of Arundel. Six years of quiet followed in which he fearlessly followed his vocation, and wrote his *Consolation for Catholics* as well as most of his poems. At length in 1592 he was betrayed into the hands of the authorities, was kept some weeks and infamously tortured ten times in the house of an abandoned ruffian named Topcliffe, then transferred to the Gatehouse, and next to a noisome dungeon in the Tower. 'Though thirteen times most cruelly tortured,' writes Cecil, 'he cannot be induced to confess anything, not even the colour of the horse whereon on a certain day he rode.' After three years' close imprisonment he wrote to entreat the grace of an open trial to Cecil, who is said to have made the brutal reply that 'if he was in so much haste to be hanged he should have his desire.' He was transferred to Newgate, and, after three days of confinement in *Limbo*, carried to Westminster for trial. The inevitable sentence followed, and on the 22d February 1595 he suffered at Tyburn, the victim of a barbarous statute, with all the high courage of the primitive martyrs. His prose writings are no longer interesting, but his poems retain their value. His longest poem is *Saint Peter's Complaint*; his most famous, *The Burning Babe*, a beautiful little piece of sanctified fancy, to have written which Ben Jonson told Drummond he would have been content to burn many of his poems.

Southwold, a Suffolk watering place, 41 miles by a small branch-line NE. of Ipswich. A municipal borough since 1489, it was almost destroyed by fire in 1659, but retained its fine Perpendicular church (1460), 144 feet long. In Southwold or Sole Bay a bloody but indecisive sea-fight was fought between the English and the Dutch on 28th May 1672. Pop. (1851) 1955; (1891) 2311.

Souvestre, Émile, French novelist and playwright, was born at Morlaix, April 15, 1806, and, after some years of struggle, drifted into journalism, and at thirty went up to Paris, where he soon made some reputation by his charming sketches of Brittany and its people. These form the still delightful books, *Les Derniers Bretons* and *Foyer Breton*, his best work. Another deservedly popular book, *Un Philosophe sous les Toits*, was crowned by the Academy in 1851. Souvestre's plays were less successful than his stories, which, although didactic, are really seldom dull. He died in Paris, 5th July 1854. His *Causeries historiques et littéraires* (2 vols. 1854) are interesting.

Souza, Madame de, a charming French writer, was born in Paris, 14th May 1761, her maiden name Adélaïde-Marie-Émilie Filleul. Her parents died early, and she was brought up in a convent, from which she emerged only to marry the Comte de Flahaut, then fifty-seven, a union which was not happy. At the outbreak of the Revolution she found refuge, together with her only son, first in Germany, then in England, and here learned of her husband's execution at Arras (1793). For solace she turned to writing, and, in the midst of grief and poverty, wrote her first book, the fresh and delightful *Adèle de Sénange* (Lond. 1794). After Thermidor she tried to return to France, but had to tarry a while at Hamburg, where she met the Marquis de Souza-Botelho (1758–1825), afterwards Portuguese minister at Paris, whom she married in 1802. The charm of her conversation and manners, her bright wit, and above all her goodness made her the queen of a group that numbered many of the most distinguished men in Paris. The Restoration brought her the great grief of long separation from her son, who had been aide-de-camp to Napoleon. She died in Paris, 16th April 1836. Later novels were *Émilie et Alphonse* (1799); *Charles et Marie* (1801), a delightful story, something in Fanny Burney's manner, and coloured throughout by English impressions; *Eugène de Rothelin* (1808), an exquisite piece of work, its hero a Grandison without insipidity; *Eugénie et Mathilde* (1811), her longest and best sustained story, in which we find close traces of her own history; and *La Comtesse de Fargy* (1822). Madame de Souza was a product of the best side of the 18th century, and she helps us to understand the politeness, the harmoniousness, the taste, the reticence—all that was noble and exquisite in the old *régime*. See Patin's *Mélanges* (1840) and Sainte-Beuve's *Portraits de Femmes*.

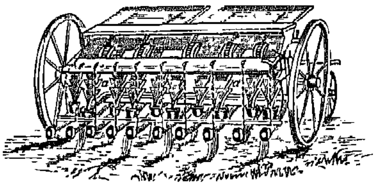
Sovereign, in Politics, the person or body of persons in whom the supreme executive and legislative power of a state is vested. In limited monarchies sovereignty is in a qualified sense ascribed to the king, who, though the supreme magistrate, is not the sole legislator. A state in which the legislative authority is not trammelled by any foreign power is called a sovereign state. See Government; and for the 20s. piece, see Pound.

Sowerby, James (1757–1822), was a native of Lambeth, who commenced as a portraitist and miniaturist, but now is remembered by his *English Botany, or Coloured Figures of all the Plants Natives of Great Britain* (36 vols. 1792–1807; new ed. 11 vols. 1863–72), the descriptions being written by Sir J. E. Smith, M.D. Other works dealt with Fungi, Conchology, and Mineralogy. Three sons who followed in their father's footsteps were James de Carle Sowerby (1787–1871), George Brettingham Sowerby (1788–1854), and Charles Edward Sowerby (1795–1842); and a son of the second was also George Brettingham Sowerby (1812–84), the author of many illustrated works on natural history.

Sowerby Bridge, a manufacturing town in the West Riding of Yorkshire, on the Calder, 3 miles SW. of Halifax. It has a town-hall (1857) and manufactures of worsted and cotton, oilcloth, chemicals, iron, &c. Tillotson was a native of the parish. Pop. (1851) 4365; (1891) 10,408.

Sowing-machines. Formerly sowing was always performed by scattering the seeds from the hand over the prepared surface of the soil. This mode, distinguished as *hand-sowing*, is still employed in many places, especially on smaller holdings and in garden husbandry. In the United States there are broadcast-sowers carried in the hand, in which a mechanism turned by a crank expels the seed from the receptacle very evenly. In the more extensive operations of the farm it has been very much superseded by the use of sowing-machines of various kinds drawn by horses—the broadcast sowing-machine, the drilling-machine, and the dibbling-machine. The first is employed exclusively for cereals and grasses, the other two for any kind of crop.

Cereals.—As above mentioned, cereals may be sown either broadcast, drilled, or dibbled. If the first method is to be adopted, the land receives what is called the seed-furrow, or, if rough, it gets a single stripe with the harrows, and the seed is then sown either by hand or by the broadcast machine. This machine consists of a triangular frame with the apex to the front, supported on three wheels, and carrying a long wooden box of the form of a triangular prism, set with a flat side—the lid—uppermost. This box, which is placed at right angles to the line of draught, is furnished with a row of small holes at the bottom, about 7 inches apart; and a little above this row is placed a longitudinal spindle, carrying a set of hard circular brushes, one opposite each hole, and deriving a rotatory motion from the axle of the hind-wheels. The size of the apertures can be adjusted to the desired quantity of seed per acre by means of a movable plate outside provided with holes corresponding to those of the box. When the box is supplied with seed, and the machine set in motion, the grain drops through the holes, which are kept from clogging by the rapid rotation of the brushes. The box is made of such a length (16 to 20 feet) that 30 to 35 acres may be sown in a day. The seed is then covered by harrowing. This machine is much used in Scotland, being rather better suited to hilly and uneven surfaces, and, from its more rapid execution, to a climate which frequently interferes with agricultural operations. In England, where the climate is more favourable and the surface more level, the drilling-machine is the favourite. So it is now in certain parts of Scotland, where the amount of seed deposited by drilling has increased immensely. The land is prepared for sowing by as complete pulverisation as possible, and its surface is made quite even by the harrow and roller. The drill (fig.), which in the arrangement of some of its essential parts corresponds to the broadcast-machine, differs from it in being furnished with a set of coulters, which are hollowed behind to enclose the lower ends of a corresponding set of tin tubes, whose upper ends are fixed opposite to the holes in the seed-box. By this machine a series of furrows of uniform depth are made by the coulters; into these furrows the seed is directed by means of the tin tubes. The modern drill-machine covers the seed most uniformly. The harrowing is generally completed before drilling begins. The spindle inside the seed-box is provided with grooved cylinders or pinions in place of brushes, and the seed-rows are generally made from 4 to 10 inches apart. The advantages of this machine over the former consist in the greater regularity of deposition of the seed, which admits of hoeing and other cleaning operations during the early period of growth; in the uniform depth at which the seed is planted, so that none of it is lost by being buried, while it is all covered; in the protection of the operation from the disturbing influence of winds; in the saving of seed and greater yield of grain, it being often found that if drilled seed be to broadcast, in quantity, as two to three, their respective yields are nearly as five to four; in the free access of sun and air during growth; and in the less liability of the crop to 'lodge' flat at the root. But it has one disadvantage: an ordinary drill cannot sow more than 10 to 12 acres per day, and employs more men and horses than the broadcast-machine. From 2 to 3 bushels of seed per acre suffices with the drill, whereas from 3 to 4 is necessary with the broadcast-machine, and from 5 to 6 bushels with the hand. The great saving of seed and other advantages thus fully atone for the extra work involved by the drill. Many kinds of grain-drills are in use in the United States; the drill for maize being a special modification of these.



Corn-drill.

The third method of machine-sowing, by dibbling, is employed chiefly on the light soils in the south of England, and now even there not generally, at least in the case of cereals, so that a minute description of the machines by which the operation is effected is unnecessary. Suffice it to mention that dibbling only requires about one-third of the seed which is necessary in drilling, and presents still greater opportunities for weeding and stirring the soil in the early stages of growth, but is attended with various important defects, and is more expensive.

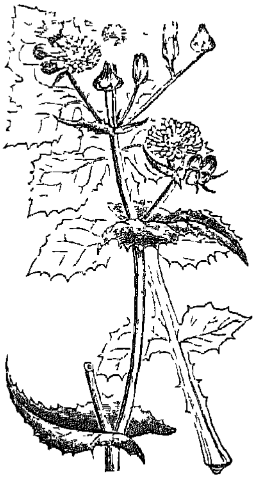
When a cereal crop is to be followed by grass the grass seeds are sown a few days, perhaps even a week or two, after the other crop by a broadcast-machine or by the hand.

Beans.—The sowing of this crop (see BEAN) is performed by means of the *bean-barrow*, a machine the same in structure as the drilling-machine for corn, but wanting the coulters, and having only three tubes, through which the seeds fall. Peas are frequently sown along with beans, the latter acting as a support to the former, and the two together better preventing the growth of weeds. The hand is also sometimes adopted.

Turnips.—For this crop the ground must be more thoroughly cleaned and broken down than for any other; after which—if the drill-system is pursued—it is formed into drills from 26 to 29 inches apart, which are then supplied with manure, and covered with the drill-plough, splitting the original drills. The new ridges thus formed being directly above the manure, the seeds are sown on the top of each ridge by means of the *turnip-drill.* This machine has, instead of a seed-box of the ordinary form, two tin or tinned-iron barrels, placed on a spindle. Each cylinder has a row of holes round its middle circumference, the row being covered by a circular sliding collar of thin metal, perforated with corresponding holes. Each seed-box has its corresponding seed-tube and hollow coulter, as in the corn-drill; but the turnip-machine has in addition a roller in front of the coulters for compressing the crests of the ridges, and some machines have two light rollers attached behind which slightly compress the earth raised by the coulters and cover the seeds. In the southern counties of England a different form of machine is used, one which sows the seed in rows on the flat surface, and perhaps at the same time drops artificial manure, or waters the seed-bed, or both.

Sow-thistle (*Sonchus*), a genus of plants of the natural order Compositæ, sub-order Cichoraceæ. The Common Sow-thistle (*S. oleraceus*) abounds in Britain and in most parts of Europe as a weed in gardens and cultivated fields. It is an annual plant, delighting in rich soils, grows to the height of 2 or 3 feet, with somewhat branching stem, and small yellow flowers in corymbs. The tender tops and leaves are much used in the north of Europe as greens. It is a favourite food with hares and rabbits, is eaten by swine, sheep, and goats, but

not relished by cattle and horses. The Corn Sow-thistle (*S. arvensis*) is a perennial with large yellow flowers, frequent in cornfields in Britain and throughout great part of Europe. Nearly allied to the genus Sonchus is Mulgedium, to which belongs the Alpine Blue Sow-thistle (*M. alpinum*), the beautiful blue flowers of which adorn some of the most inaccessible spots of the mountains of Switzerland and of Scotland.



Sow-thistle (*Sonchus oleraceus*).

Soy is a thick and piquant sauce made from the seeds of the Soy Bean (*Soja hispida*), a plant of the natural order Leguminosæ, sub-order Papilionaceæ. It is a native of China, Japan, and the Moluccas, and is much cultivated in China and Japan. It is also common in India, although probably not a native of that country. The seeds resemble those of the Kidney Bean, and are used in the same way. The Japanese name is *Shōyu* (see JAPAN, Vol. VI. p. 286). Soy is made by mixing the beans softened by boiling with an equal quantity of wheat or barley roughly ground. The mixture is covered up and kept in a warm place to ferment, then put into a pot and covered with salt. Water is poured over the mass, and it is stirred at least once a day for two months, after which the liquor is poured off and squeezed from the mass, filtered, and preserved in wooden vessels.

Soyer, ALEXIS, cook and author of books on gastronomy, was born at Meaux in the cheese-producing district of Brie in 1809, and, designed for the church, was trained as chorister in Bossuet's famous old cathedral. But his inclinations turned another way: he went through a systematic training as cook in several notable restaurants in the provinces and in Paris, and, suppressing some temptation to give scope to his dramatic powers and fine voice on the stage, he became the most famous cook of his time. He had a post in Prince Polignac's kitchen in 1830, and was nearly murdered there by the revolutionists, but escaped to London, and was cook in various hotels, private houses, and latterly in the Reform Club (1837–50). For a time he managed a 'symposium' or restaurant of his own. He had gone to Ireland during the famine (1847); contributed greatly to improving the food of the army and navy; and in 1855 he went for a time to the Crimea to reform the food-system under which the army was suffering. His works greatly increased the public interest in economic, scientific, and tasteful cookery, and comprised *Culinary Relaxations* (1845); *Charitable Cookery* (1847); *The Gastronomic Regenerator* (1846; 9th ed. 1861); *The Modern Housewife* (1849; 36th thousand, 1866; new ed. 1872); *Shilling Cookery-book* (1854; 123d thousand, 1858). He wrote also an account of his experiences in the Crimea, and died 5th August 1858. Memoirs by Volant and Warren were published in 1858.

Spa, a watering-place of Belgium, stands amid wooded and romantic hills 20 miles by rail SE. of Liége. The principal buildings are the casino, bath house, and similar institutions for the use of visitors. One of the chief charms of the place is its beautiful drives. The springs, all chalybeate and alkaline, are cold, bright, and sparkling, and efficacious in anæmic complaints, nervous diseases, &c. This water is exported to all quarters of the globe. Spa is famed for the manufacture of fancy wooden lacquered ware. Pop. 7278. The number of visitors during the season is about 12,000. The virtue of the waters was known as early as the 14th century, and the place was particularly famous as a fashionable resort in the 16th and 18th centuries. It is from this Spa that the generic term for a watering-place or fashionable mineral baths is derived.

Spaccaforno, a town in the south-east corner of Sicily, 30 miles SW. of Syracuse. In an adjoining valley are some remarkable 'Troglodyte' caves, ranged tier upon tier. Pop. 8588.

Space. See PSYCHOLOGY, Vol. VIII. p. 475; DIMENSION; and GEOMETRY.

Spade-husbandry. The operation of digging is performed with a spade, or pronged fork, or with a steam-digger. The spade or fork is thrust in with the foot, and the mass of earth is first loosened by the lever-power of the handle, then lifted and inverted. When this operation is performed in spring or summer, the ground should be dry, so as to obtain pulverisation as easily and to as great extent as possible. In stronger soils, which are dug in autumn, a little moisture is desirable, as the land lies fallow, and the frosts of winter afterwards pulverise and reduce it to a proper degree for receiving the crops in spring. Digging by hand is mainly confined to the cultivation of gardens and small 'crofts,' for, though a most efficient means of cultivating the soil, it is too expensive for field crops. It is resorted to, however, for digging over or trenching land which has been in timber or full of stones or boulders. Formerly the spade was the only implement used for digging, but steel forks are now more largely used, being lighter and more easily driven into the soil. Besides preparing the land for plants, the spade and the fork, chiefly the latter, are used for taking crops, such as potatoes and carrots, out of the ground. For the important subject of spade-husbandry and cottage-farming as an economic and social problem, see PEASANT PROPRIETORSHIP.

Spadix. See SPATHE.

Spagnoletto. See RIBERA.

Spahi, the Turkish form of the Persian word *Sipahi* (from which we get Sepoy), was the term for the irregular cavalry of the Turkish armies before the reorganisation of 1836.

Spain (Span. *España*) occupies the larger part of the south-western peninsula of Europe, and attains in Cape Tarifa the most southerly point of the whole continent. It lies between 43° 45′ and 36° 1′ N. lat., and between 3° 20′ E. and 9° 32′ W. long. It is bounded on the N. by the Bay of Biscay and by the Pyrenees, on the E. and S. by the Mediterranean, on the SW., W., and NW. by the Atlantic and by Portugal. From Fuenterrabia in the north to Tarifa in the south is 560, from Cape Finisterre in the north-west to Cape Creux in the north-east is 650 miles. The area is 191,367 sq. m.; the population in 1890 was estimated at 17,500,000. The country, including the Balearic and Canary Isles, was divided in 1834 into forty-nine provinces; but the names of the fourteen more ancient kingdoms, states, and provinces are still in use. The following table gives the names of the ancient and modern provinces, with their area and population, according to the census of 1887.

Coast-line.—The coast-line is estimated at 1317 miles, of which 712 belong to the Mediterranean and 605 to the Atlantic. Spain has thus but 1 mile of coast-line to 145 sq. miles of area, while Italy has 1 to 40 and Greece 1 to 7. The shore of the Bay of Biscay presents an almost unbroken wall of mountain and rock, but in the north-west and west appears the most southerly prolongation of the fiord or firth system of Norway, western Scotland and Ireland, forming as usual fine harbours—Ferrol, Corunna, Vigo, &c. Portugal indents a frontier of nearly 400 miles; to the south, from Portugal to Gibraltar, the Atlantic coast is low. Cadiz is here the chief harbour. The southern Mediterranean shore is rocky, backed up by the huge mass of the Sierra Nevada and its prolongations to Cape Gata. Malaga and Almeria are the chief harbours here; in the south-east and east are the naval arsenal of Cartagena and the commercial ports of Valencia and Barcelona and others. Though almost a peninsula, this uniform character of the coast-line and the great elevation of its central plateau give Spain a more continental character in its extreme range of temperature than any of the other peninsulas of Europe. The greater part of its surface consists of a plateau of between 2000 and 3000 feet above the sea-level, traversed by loftier ranges. On the east the plateau is buttressed by chains which descend rapidly to the Mediterranean. The mountains of Oca, the Sierra de Moncayo, and the Idubeda Mountains rise sharply from the valley of the Ebro on the north; the Sierra Morena on the south is of inferior elevation; the western ranges run into the frontier of Portugal, and lose themselves in the Atlantic. Outside the plateau lie the highest summits of the whole country, the Pic de Néthou in the Pyrenees (11,151 feet), and the Pic de Velate in the Sierra Nevada (11,670), while the Picos de Europa in the Cantabrian Range attain over 8000 feet. The plateau itself is traversed by four mountain-ranges, the Oca and Idubeda Mountains above mentioned, which separate the valley of the Ebro from that of the Douro; the Guadarrama Range, which divides this river from the basin of the Tagus; the Sierra de Toledo, which forms the watershed between the Tagus and the Guadiana; while the southern buttress, the Sierra Morena, forms the northern wall of the valley of the Guadalquivir. The whole plateau has a general slight inclination from east or north-east to south-west, and hence all the considerable rivers of Spain except the Ebro flow westward to the Atlantic. The general elevation of the plateau conceals the real height of its mountains and passes; thus, the highest point of the railway from the north to Madrid is about 60 feet higher than the tunnel of Mont Cenis, and that of the old coach-road through the Guadarrama is 300 feet higher still.

Geology.—A mass of granitic, Cambrian, and Silurian rocks extends from Galicia south-east to the valley of the Guadalquivir. The Carboniferous formation occupies the north and south-west corners of the great plateau. The valley of the Ebro is a trough of Secondary rocks extending from the Bay of Biscay to the Mediterranean; another band of Secondary rocks forms the region of Andalusia south of the Guadalquivir; the Upper Cretaceous formation stretches from the basin of the Ebro to the granite of the Guadarrama and to the east of Madrid; these older formations are overlaid by Tertiary, Eocene and Miocene, marine and fresh-water deposits. The visible surface of Spain consists of 37 per cent. of crystalline and Palæozoic rocks, 34 per cent. of Tertiary, 19 of Secondary rocks, and 10 per cent. of Quaternary deposits. The remains of undoubted volcanoes are found at Olot in Catalonia, at Cabo de Gata in the south-east, and at Ciudad Real in La Mancha. To the frequency of older igneous action, and to the fractured condition of the later rocks, is perhaps due the great mineral wealth of Spain.

Climate and Products.—The configuration of the country renders the climate very varied. In parts of the north-west the rainfall is among the heaviest in Europe. In the east and south-east occasionally no rain falls in the whole year. Even in the north the contrasts are striking. The rainfall in the Western Pyrenees is very great, yet on the northern slope of the valley of the Ebro there are districts almost rainless. The western side of the great plateau, speaking generally, is more humid and much colder than the eastern, where irrigation is necessary for successful cultivation. With this difference in climate goes a corresponding difference in products. Galicia is almost a cattle country;

Estremadura possesses vast flocks of sheep and herds of swine. The vegetable productions of Galicia and the Asturias are almost those of Devonshire and of south-west Ireland. Till the 18th century cider was the great beverage in the north; but in the basin of the Minho, in the Riojas on the Ebro, in Navarre, Aragon, and Catalonia strong red wines are grown in abundance. The productions of Catalonia and Tarragona are almost those of Provence and the Riviera. The plains of Leon and of Old and New Castile are excellent corn-growing regions. From Valencia southwards the products are semi-tropical: the climate is almost more tropical than that of the opposite coast of Africa. Fruits of all kinds, luscious or fiery wines, oil, rice, esparto grass, and sugar are common along the coast. No other part of the soil of Europe is so rich in varied produce. It is curious to note how much of this is originally exotic, but has become naturalised. Like all other countries of western Europe, the agriculture of Spain has been depressed of late years by competition with America; but her export of wine to France has been greatly increased owing first to the destruction of the French vineyards by the phylloxera, and afterwards to the war of tariffs between France and Italy; the export of wine to France is over £10,000,000, while that to England is only £866,000. The quantity of agricultural produce in Spain in cereals, wine, oil, and fruit seems to be limited only by the paying demand, and is checked only by the cheaper competition of other countries. Large tracts of Spain once cultivated in Roman or in Moorish times now lie abandoned and unproductive; 46 per cent. of the territory is uncultivated.

Population.—For a moment in the 16th century Spain was the most important country in Europe; but the population was unequal to the drain upon it caused by constant warfare, emigration, expulsion of portions of the inhabitants of the peninsula, and above all by adverse economical and industrial conditions. Thus a population of over 10 millons at the end of the 15th and beginning of the 16th centuries fell to little more than 6 millions in the 17th; the numbers then slowly rose: (1768) 9,307,804; (1797) 10,541,221; (1857) 15,464,340; (1860) 15,673,536; (1870) 16,835,506. Spain, if the census can be trusted, has increased in population some 7,000,000 during the 19th century. As in other countries, the town and industrial population has augmented in a greater ratio than the rural and agricultural. In 1887 there were in Spain one city with over 400,000 inhabitants, Madrid; one of 250,000, Barcelona; three of between 150,000 and 100,000, Seville, Valencia, and Malaga. The most densely populated provinces are Madrid, Barcelona, Galicia, and the Basque Provinces. Emigration, which is steadily on the increase, is proving a heavy drain on the country; already there are not enough labourers in the agricultural districts, and every year thousands of families are seeking new homes and higher wages in South America, Algeria, and elsewhere.

Industries.—Some 60 or 70 per cent. of the population are engaged in agriculture of various kinds, and 10 or 11 per cent. in mining or manufacturing industries and trade. Since the sale of church, crown, and much of the municipal property during the 19th century the land has become much divided; it is estimated that there are about 3½ millions of farms, of which ¾ million are occupied by tenants, the rest by proprietors. The seat of the manufacturing industries—mainly cotton—is chiefly Catalonia; and the manufacture of corks (1,400,000,000 yearly) employs over 8000 men in that province. The mineral wealth is more widely distributed—iron in Biscay and the province of Huelva; copper at Huelva, in the Rio Tinto and Tharsis mines; lead at Linares; quicksilver at Almaden; coal chiefly in the Asturias; salt in Catalonia, and by evaporation near Cadiz. The amount produced in 1888 was as follows:

Minerals	Production in Tons.	Exported in Tons
Iron	5,609,876	4,464,355
Lead	356,545	2,168
Argentiferous Lead	183,441	8,825
Copper	3,202,416	825,046
Zinc	74,353	32,004
Quicksilver	27,847	..
Salt	413,886	235,182
Coal, Coke	1,225,173	.

Smelted Metals	Production in Tons	Exported in Tons.
Iron and Steel	252,116	96,801
Lead	161,462	58,957
Argentiferous Lead	73,376	70,636
Copper	70,719	45,080
Zinc	26,173	1,089
Quicksilver	1,865	1,104

Until lately the only *religion* tolerated was that of the state, the Roman Catholic; now a certain toleration is allowed to other denominations. The Catholic clergy are paid by the state; ecclesiastical matters are regulated by the Concordat of 1851. There are nine archbishops, with fifty-seven suffragan bishops, four unattached bishops, and about 35,000 clergy. Since 1868 the theological education is given in seminaries entirely under the hands of the bishops.

Education varies greatly among different classes and in different provinces. In the large towns and in some of the provinces a great effort is made to keep the higher and the technical schools on a level with the best in other European countries. In other parts the neglect is very great. There are ten universities—Madrid, Barcelona, Granada, Oviedo, Salamanca, Seville, Santiago, Valencia, Valladolid, and Saragossa: the number of students is about 17,000. In the episcopal seminaries and religious schools about 9000 are educated. Of secondary institutions there are about 70, with 356 affiliated colleges. The primary schools number some 25,000, with 1,500,000 pupils, and the private schools 5000, with about 300,000 pupils. Many of the primary schools in the provinces are in a wretched condition, the salary of the teachers being only about £5 per annum, and the buildings and other appliances to match. The great fault of the higher Spanish education is in the numbers who press into professional, literary, and political careers in comparison with those who dedicate themselves to commercial, industrial, or agricultural pursuits. By reason of this Spain loses great part of the advantages of her natural wealth. All her principal mines are worked, her railways built, schemes of irrigation carried out with foreign capital, and in spite of the excellence of her labourers the higher employees are often foreigners. The progress of agriculture is impeded in the same way, and legislation is too often founded on merely theoretical ideas, instead of any practical knowledge of the real needs of the country.

The total *imports* and *exports* of Spain have much increased of late years. The imports in 1877 amounted to £16,340,672, and the exports to £18,175,140; in 1887 £22,550,072 and £25,326,612; in 1890 £37,645,517 and £37,510,395 respectively. The recent increase is chiefly due to the export of wine to France and imports from that country. The exports from Spain to Great Britain are about £11,500,000, and the imports £5,000,000; but the statistics are always behind-hand and often very confused. Since October 1848 over 6000 miles of *railway* have been constructed. Madrid, the capital, is now in railway communication with all the chief harbours and commercial routes in the kingdom, and also with Portugal. Two lines at either extremity of the Pyrenees connect the Spanish with the French and European lines, and a third was in 1892 constructed through the centre of the chain. 10,670 miles of telegraph are open.

The *government* of Spain is a hereditary monarchy founded on the constitution of 1876. The Cortes consists of two bodies—the Senate, one-third of the members of which sit by hereditary right, one-third are appointed by the sovereign for life, and one-third elective. The Chamber of Deputies is elected at the rate of one member to every 50,000 inhabitants. Universal suffrage (1890) and trial by jury have lately been introduced. The provinces are administered by governors and provincial deputations, and the towns by alcaldes and municipal councils, all formed more or less after the model of the French prefects, councils-general, maire, &c. All these and other employees are under the control of the government, who are thus able to manipulate elections, except in the large towns. The public debt of Spain, funded and floating, is about £259,900,000, bearing an interest at 4 per cent. of over £10,750,000. The revenue and expenditure, nominally nearly balanced, have risen from £31,000,000 in 1881 to £35,000,000 in 1891, and the wealth of the country is gradually increasing.

The *navy* of Spain consists of one large ironclad, 10 of from 7 to 9000 tons, 20 of the second class, and of over 80 vessels of smaller size. The *army* on a peace footing is 95,000, not including the *Guardia civil*, or gendarmes, the *Carabineros*, and other active or reserve forces. In war time the numbers officially supposed to be capable of serving amount to 450,000.

The legal official currency is founded like the French on a decimal system, the *peseta* of 9·6 pence being the unit; but the terms of the older coinage are still in use, especially for copper money and small change. The legal measures are still more closely copied from those of France; but the older measures of capacity and weights are still in use in many of the provinces.

See, besides the standard Spanish topographical and statistical books, Borrow's *Bible in Spain*, Ford's *Handbook* and *Gatherings from Spain*, A. J. C. Hare's *Wanderings in Spain*, and later books on the country and its life by Mrs Harvey (1875), Rose (1875–77), Campion (1876), Frances Elliot (1882), Gallenga (1883), Hope-Edwardes (1883), Olive Patch (1884), Willkomm (Prague, 1884), Lomas (1885), Parlow (Leip. 1888), H. T. Finck (1891), and the present writer (1881).

HISTORY.—Spain (*Spania*, *Hispania*, *Iberia* of the Greeks and Romans), from its position as the south-west peninsula of Europe, beyond which was the ocean only, early became a very eddy of tribes and races. Its prehistoric ethnology is not determined. The earliest race of which we have authentic testimony is the Iberian. It occupied nearly the whole of Spain and the south of France before the Roman conquest. Overlying these Iberian tribes are probably two invasions of Celtic peoples: the earlier mingled with the Iberians, and formed the Celtiberian tribes of central and western Spain; the later has left the more purely Celtic names in the north and north-west. There was probably never any Iberian nation—only a congeries of tribes of the same race like that of the North American Indians, but in a higher state of civilisation—a civilisation excelling that of contemporaneous Gaul or the more purely Celtic tribes to the north. The Iberians were adepts at mining, and used writing (see BASQUES). Omitting traces left by mere traders, such as the Phœnicians on the south and south-west, the Egyptians on the east, Greeks from Massilia on the north-east, the first power which seriously attempted to occupy Spain was Carthage (q.v.). The Carthaginians had probably succeeded to the commercial enterprises of their mother-country Phœnicia; but it was not until they had retired baffled from Sicily that the occupation of Spain was seriously begun. Hamilcar, first of the great line of Carthaginian generals, opened the conquest in 238 B.C. (see CARTHAGE, HAMILCAR, HANNIBAL). Here again they were met and thwarted by the Romans (see ROME, HANNIBAL, SCIPIO). It then became the task of the Romans to conquer Spain. In subjugating the Iberian and Celtiberian tribes of Spain they found far greater difficulty than with any more purely Celtic race. Spain early showed her tenacity of resistance. The sieges of Saguntum, Numantia, Clunia are memorable in history. Even when conquest seemed assured Viriathus (147–140 B.C.), probably a native, and Sertorius, a Sabine leader (83–72 B.C.), tried the capacity of the best generals of Rome. It was in Spain too that the final issue between Cæsar and the Pompeians was fought out at Munda. Spain was not completely brought under Roman rule till the time of Augustus. Once subdued, it became thoroughly Roman. The impress of Rome has been deeper on the language, manners, and religion of Spain than on those of any other country. Under the Romans Spain was divided first into two provinces—Nearer and Farther Spain: in the time of Augustus these became three—Bætica, embracing nearly the modern Andalusia; Lusitania, Portugal with some of the western Spanish provinces; and Tarraconensis, comprising the remainder of the country. Local rule and customs and speech were, however, not wholly obliterated in the varied Municipia and Respublicæ. Celtiberian coinage continued contemporaneously with that of Rome, and for probably 200 years after Augustus. All the great arts and works of Roman civilisation flourished. Latin was the language of the educated classes, and Spain furnished a large contingent of authors to the silver age—Martial, Seneca, Quintilian, Lucan, Silius Italicus, Columella, Pomponius Mela. Trajan was a Spaniard. Some of Spain's greatest cities still bear Latin names—Legio (Leon), Emerita Augusta (Merida), Cæsar Augusta (Zaragoza or Saragossa), Pompeiopolis (Pamplona). During Roman rule Christianity was introduced into Spain, and rapidly spread. In 325 A.D., at the Council of Nicea, Hosius of Cordova was the greatest name in the west, overshadowing that of the bishop of Rome. Prudentius (338–405), almost the first Latin Christian poet, was a native of northern Spain. Two centuries later (560–636) Isidore, bishop of Seville, was the most learned writer of the west.

With all western Europe Spain felt the effects of the downfall of the Roman empire. The native Spanish legionaries were serving in all parts of the empire; barely two foreign legions garrisoned the whole of Spain. Thus, when the Suevi, Alans, Vandals (*c.* 409), Visigoths (414; see GOTHS) invaded Spain, the country, which had cost the Romans two centuries to subdue, had little means of resistance. The Suevi established themselves in Galicia and Lusitania, the Vandals penetrated farther south, and gave their name to (V)andalusia; thence in 429 they crossed to Africa. The Visigoths brought with them more than a tinge of Roman civilisation. Though both Visigoths and Vandals were nominally Christians, their Arian heresy placed them in opposition to the native bishops, the most ardent defenders of the Nicene faith. For some time Spain was only a province of a larger Visigothic kingdom. Theudis (573) was the first Visigothic king who fixed his court in Spain. It was not till the reign of Leovigild (584) that the Suevi were definitely dispossessed, and not till the reign of Suintilla (624) that the Byzantine Romans were finally expelled from the east coast; and even to the end they retained the Straits of Gibraltar and a few towns in southern Portugal; and some native tribes in the Orospeda Mountains preserved their independence. The abjuration of Arianism by the sons of Leovigild strengthened the church at the expense of the monarchy. The bishops were supreme in the councils of Toledo, which were also the chief councils of the state. The Jews, unmolested by the Arians, were now persecuted and rendered hostile. They intrigued with the Mohammedan Arabs, who had conquered North Africa and crushed out Christianity. Their assistance and that of the count of the Roman possessions in the straits enabled Tarik to land at Tarifa; and the Gothic monarchy was destroyed at the battle of the Guadelete (711), where fell also Roderic, last of the Gothic kings. The chief mark left by the Goths in Spain was in legislation; first in the *Lex Romana Visigothorum*, then in the *Fuero Juzgo* or *Forum Judicum*. The tradition of a conquering caste and the events of the reconquest made the Spanish aristocracy look on the Visigoths as the English gentry do on the Normans; otherwise their influence has been exaggerated. The few remains of art are copies of Byzantine models. Of literature not a trace remains.

The Moors in Spain.—Seldom has there been so rapid a conquest as that of Spain by the Arabs and Moors. In 714 they had gained the whole of Spain except the north and north-west. In 719 they had added the Narbonnaise to their dominions; in 732 they reached their extreme northern limit when defeated by Charles Martel at the battle of Tours. The Arabs and Moors were divided by racial, tribal, sectarian, and dynastic differences. The old quarrels which had existed in Arabia before the time of Mohammed broke out again in Spain as soon as the first enthusiasm of conquest had subsided. Arabs and Berbers of North Africa were ever at strife; the feuds between the sects of Islam raged bitterly in Spain, and the claims of rival dynasties—e.g. the Abbasides and Ommiades—weakened the common cause. Whenever the Moors were united the progress of the reconquest was checked; the Christians gained ground when division and disunion spread among the invaders. The final expulsion was delayed for centuries through the civil strife of the Christian kingdoms. The rule of the early emirs was by no means harsh; a Gothic chief Theodoric preserved an independent Christian kingdom, Todmir, in Valencia and the neighbouring provinces. The Jews were treated almost as equals, the Christian religion was tolerated to the Mozarabes (see MORISCOS). There were differences in the several provinces, but at Cordova only, which became the capital of the western califate (see CALIF, MOORS), was any persistent persecution carried on. Under Abderrahman I., the heir of the Ommiades, and his successors the Arab rule in Spain attained its highest glories. He (756) and his son Hakam I. (796) made Cordova the finest city in the west; its mosque (786–796) is still one of the grandest remains of Arabic architecture. No Christian people in the west was then capable of such work. The greatest chief of this period was Almansor, who forced back the tide of Christian conquest and penetrated to Compostella in Galicia (997); but all his conquests were lost at Catalañazor (1002). Many Moorish names survive in Spanish topography (see NAMES). The origin of the various Spanish kingdoms of the reconquest is obscure. Pelayo, said to be of Gothic or mixed Roman blood, began the reconquest at Covadonga in 718. A little later a distinct organised resistance commenced in Navarre and in Aragon. The counts of Barcelona established themselves in the Spanish March which dated from Charlemagne (q.v.) and Louis. The most important of these kingdoms was that of Asturias. Galicia on the west was soon annexed to it, then Leon to the south. Alfonso I. (739–756) had already overrun the country as far as the Mondego and the Sierra de Guadarrama. Alfonso II. (791–842), the ally of Charlemagne, pushed his raids as far as Lisbon, and founded in the north the cities of Compostella and Oviedo. Alfonso III. (866–909) removed the capital to Leon, and reached in one expedition the Sierra Morena. The unwise division of his dominions among his sons retarded the advance for a time. After the battle of Catalañazor the Christian frontier stretched from the Tagus to Tudela on the Ebro; and Castile (the land of frontier castles), which had been governed from 932 by semi-independent counts, rose into a new kingdom. From this period date the constitutional liberties of Spain. The councils summoned by the king continued those of Toledo, and were as much political as ecclesiastical: assemblies of the nobles and magnates to settle the succession or election of kings were held in 931 and 933; but the first more general Cortes was that of Leon, 1020. In it was established the right of *behetria*—i.e. of changing lords, which in Spain prevented many of the worst feudal abuses, but encouraged civil war. Many of the fueros were now granted in order to attract defenders to towns reconquered and denuded of inhabitants (see FUERO).

After the death of Bermudo III. (1037) the crowns of Leon and Castile were united under Ferdinand the Great; his son, Alfonso VI., by his capture of Toledo (1085) made the Christian power predominate. In spite of a defeat at Zalacca (1086) and at Ucles (1108), Toledo was never reconquered by the infidels, and the Guadiana instead of the Tagus was now the Christian boundary. To the reign of Alfonso VI. belongs the story of the Cid (q.v.), of his strange career as ally alternately of Moor and Christian, of his occupation of Valencia from 1096 to 1102. Henry of Burgundy founded the country or kingdom of Portugal in 1095 (see PORTUGAL). Alfonso VII. lost the battle of Alarcos (1194), but the great victory of Navas de Tolosa (1212), under the allied kings of Castile, Navarre, and Aragon, broke entirely the power of the Almohades, and made New Castile secure. The separation of Leon from Castile (1157–1230) weakened for a time the Christian forces. Under St Ferdinand, the grandson of Alfonso IX., the crowns of Leon and Castile were finally united. He wrested Cordova from the Moors (1236), Jaen (1246), Seville (1247), Jerez and Cadiz (1250), Granada became a tributary kingdom, and the line of the Guadalquivir was held by the military orders of Calatrava, Santiago, and Alcantara. Ferdinand died in 1252. Navarre (q.v.) by the succession of the line of Champagne had become almost a French kingdom. To the east Saragossa had been taken in 1118. Valencia had been lost for a time, but first Majorca and the Balearic Isles (1228), then Valencia (1237) fell before the arms of Jaime I. of Aragon, and Murcia was won for Castile (1244).

In constitutional progress Navarre and Aragon kept pace with Castile. Each had its separate Cortes, with three estates in Navarre and four in Aragon, and its own code of laws. Castile used the *Fuero Juzgo* and the *Fuero Real*, limited by local fueros; in Navarre and Aragon the fuero was supreme. Catalonia had her *usatges*. The *Siete Partidas* of Alfonso X. did not become law till 1384. In ecclesiastical matters Spain had become more closely papal; the Roman rite had superseded the Isidorian or Mozarabic after the taking of Toledo; the finest of the cathedrals of Spain—Leon, Burgos, Toledo, &c.—date from this period. Christian Spain had increased immensely in wealth, yet it took nearly two and a half centuries to destroy the remains of Moorish power. The period between the death of St Ferdinand and the accession of Isabella of Castile (1468) was one of trouble and almost constant civil war. The influence of the Moors on Christians was in some ways more marked than before. Alfonso the Wise (1252-84) in his court at Toledo adopted the best of Moorish science and literature, and the philosophy and art which they had acquired from the Greeks and Byzantines, and henceforth Spanish was not inferior to Moorish civilisation. A century later the Moorish influence was almost wholly ill in the Sevillan court of Pedro the Cruel, the ally of the Black Prince, whose whole career and death by his brother's hand was more like that of an oriental sultan than of a western monarch. The troubles of Castile arose from disputed successions, from long minorities, from the claim of the nobles, even those of the royal family, to transfer their allegiance to any sovereign they might choose (*behetria*). The Infantes de la Cerda and Henry of Trastamare acted alternately as subjects of Castile, Aragon, or France, or entered into alliance with the Moors, as might serve their private interests. The only trustworthy allies of the crown were the burghers and the clergy, but the rivalry of the cities made their allegiance doubtful. At the death of Henry IV. (1474) the crown of Castile was left with two female claimants, his daughter Juana (the Beltranaja) and his sister Isabella. The election of the former meant union with Portugal; by the marriage of Isabella with Ferdinand of Aragon her election united Castile and Aragon. Under a series of strong monarchs, whose authority was limited by a powerful aristocracy, Aragon had become a strong Mediterranean power—to the Balearic Isles had been nominally added Corsica and Sardinia, more really Sicily and Naples, with claims on Northern Italy; these claims and possessions after the union led to the waste of Spanish blood and treasure for centuries, without any corresponding advantages. The conquests from the Moors in this period were few but important—Tarifa (1292), to recover which the African Moors made their final effort of conquest; their defeat on the Salado (1340) entailed the loss of Algeciras in 1344; and Gibraltar, which they had recovered after 1309, became Spanish in 1462. Henceforth the Moors existed in the Peninsula on sufferance only, while the Christians were gathering their forces for the final blow.

Small as were the resources left to the Moors, they were weakened still further by dissensions in the ruling families. Boabdil, the last king of Granada, would have made terms with Castile; his uncle, Muley Hacem of Malaga, and his nephew, El Zagal, opposed a strenuous resistance. Alhama was taken 1482, Ronda 1485, Malaga 1487, Baza 1488, and the Spanish sovereigns with an army of 100,000 men sat down to the siege of Granada in 1491. January 2, 1492, the city surrendered; October 12, 1492, Columbus discovered America; in 1512, after the death of Isabella, Ferdinand wrested Spanish Navarre from its Gascon kings.

Henceforth the history of Spain is no longer exclusively Spanish, but also European. The whole of the Peninsula except Portugal was united under one rule, but true political unity was very far from having been attained. Aragon and Navarre still preserved their separate Cortes, privileges, and regnal titles; the Basque Provinces continued almost a republic under a Spanish suzerain. In Castile, however, the royal power had been greatly strengthened; the fatal mistake of the *procuradores* in accepting royal pay under Pedro the Cruel ensured the ultimate subserviency of Cortes. The masterships of the great military orders had become the gift of the crown in 1476, and in 1513 Pope Hadrian VI. annexed them permanently to it; the Hermandades (q.v.), or ancient associations, first of the bishops, afterwards of civil bodies, for defence of their rights and for the suppression of disorder, became a powerful governmental police; the Inquisition, first employed on a large scale against the Albigenses by the Dominicans in 1248, had been remodelled (1478) to the profit of the crown. But the increased power of the monarchy lay chiefly in the condition of the conquered provinces. Their incorporation was an immense gain to the country, but it gave the king a basis for despotism, and a standing force wherewith he could crush any revolt in the north. The still advancing wave of Mohammedan power was not finally rolled back until the battle of Lepanto (1571) and the raising of the siege of Vienna (1683). The Moors of Barbary were still able to harass Spain and seriously to check her trade; but the most fatal legacy of the Moors was the fact that Spain had won her glory as champion of Christianity against Islam in the peninsula, and continuing this rôle she wasted all her resources, and failed, as champion of Roman Catholicism against Protestantism in Europe.

On the death of Isabella her eldest daughter Joana, who had been married to Philip, son of the Archduke Maximilian, sovereign of the Netherlands, succeeded, jointly with her husband, to Castile. Ferdinand retired to Aragon. Philip died in 1506, and Ferdinand resumed the government of Castile as regent for his daughter, who was incapacitated by insanity. Ten years afterwards he died, leaving all his kingdoms to Juana, with her son Charles as regent. Till the arrival of Charles Spain was really governed by Archbishop Ximenez (q.v.), whose work in the interest of the crown was almost as important in Spain as that of Richelieu later in France; his intolerance to the conquered Moors brought on revolts, and all the subsequent troubles with the Moriscos were the result of the policy which he initiated. For the history of Charles I. as Charles V. Emperor of Germany, and of his action towards the Protestants and his campaigns in Italy and Germany, see CHARLES V. His reign was marked by the triumph of absolutism in Castile. His appointment of Flemings to high offices in Spain, and his exorbitant demands for supplies, led to the rising of the cities of Castile and to the war of the *comuneros*. These were vanquished at Villalar in 1521, and Toledo surrendered soon afterwards. A more popular movement in Valencia was crushed by the nobles of that province. Charles by timely appointments had separated the cause of the nobility from that of the cities; and on the refusal in 1538 of the nobles and clergy to share the burden of taxation these bodies ceased to be summoned to Cortes. The conquest of Tunis in 1535 was a brilliant feat of arms; the attempt on Algiers (1541) utterly failed. The troubles in Germany prevented Charles from following up these campaigns, which might have had results of great benefit to Spain. Worn out by disease, frustrated in all his plans, having failed in the election of his son Philip as emperor, Charles resigned first his hereditary dominions in 1555, and in 1556 abdicated the empire in favour of his brother Ferdinand, and his other crowns in favour of Philip, and retired to the monastery of Yuste, where he died in 1558.

When Philip II. (q.v.) ascended the throne of Spain her dominions were at their greatest. Spain, to which Portugal was added in 1580, Sicily, a great part of Italy, the Low Countries (Holland and Belgium), the whole of North America except the English and French possessions, the whole of South America after 1580, the Philippine and other islands in the East, and possessions in Africa formed the first empire on which it could be said that the sun never set. Philip had inherited the difficulties and complications of his father's policy without his father's ability. Dull, tenacious, yet irresolute, the type of a conscientious bigot, he lived ruthlessly up to his own ideal. He acted as the champion of orthodoxy in Europe; wherever the faith was in danger there would he protect it. He sacrificed everything to this. And he ruled alone, with no assistant body of councillors, with secretaries only. Well served he was by generals, ambassadors, admirals, by great men in all departments; he had the finest fleets and armies of his age; he never swerved from his purpose; he did not, like his father, retire when baffled, but died working in his life's cause to the end. His return to Spain in 1559 was marked by his presence at the autos de fé at Valladolid and Seville. He failed in his attempts on Tunis and Algiers, but raised the siege of Malta in 1565; he put down the rebellion of the Moriscos in 1568–71, and Don John of Austria gained for him in 1571 the great sea-fight of Lepanto, which stayed the advance of the Turks in the Mediterranean. The action of Philip in introducing the Inquisition (q.v.), popular among the lower classes in Spain, but abhorred elsewhere, the license of the Spanish soldiery, and the stern rule of Alba produced a revolt in Flanders in 1559, which led to the formation of the United Provinces in 1609 (see HOLLAND). The abilities of the regents and generals, especially of the Duke of Parma, who took Antwerp in 1585, gave for a time hope of reconquest; but the loss of the Armada (1588), and the diversion of Parma's forces against France (1590–92), made the contest hopeless. Henceforth Philip's power evidently declined. A quarrel with his secretary, Antonio Perez, led to an outbreak in Aragon and the restriction of its liberties in 1592. His communications and commerce with the colonies and with Flanders were continually threatened by Dutch and English corsairs. Philip had introduced the practice of raising money in Spain without consent of the Cortes, which was no longer regularly summoned. From ignorance of the true principles of political economy the very wealth of Spain hastened her decline. The false colonial policy of the time, with its restrictions and monopolies, gave all the profit of the commerce to contraband trade; the supply of only the precious metals made gold and silver cheaper in Spain than elsewhere and all other commodities dearer. Her rising industries died away. The bullion left her to purchase from foreigners things which she no longer produced and for which she had nothing else to give. Districts cultivated by the Moors became desert, population declined, and both the forces and resources of Spain by sea and land diminished yearly. Philip II. died September 13, 1598, in the palace of the Escorial.

Philip II. had reigned alone; with his son Philip III. began the reign of favourites, which continued with slight intermissions through both Austrian and Bourbon dynasties to the Revolution. The Duke of Lerma was the real sovereign. The ability of Spinola, who recovered Ostend in 1604, and of the captains trained in the school of Flanders upheld the prestige of the Spanish arms for a while; but her power was declining. The expulsion of the Moriscos, an agricultural population, in 1609 weakened her still more. In 1618 Lerma fell from power, but no improvement took place. Philip IV. (1621–65) possessed some taste for literature and art, but was as incapable of governing as his father. In the Thirty Years' War Spain fought on the side of the emperor, and her soldiers greatly contributed to his success, but she had no share in the profit. The government was in the hands of the Conde-Duke of Olivares, whose ambitious projects and wasteful expenditure introduced corruption everywhere. All offices became venal. The rights of the more independent kingdoms of Spain were violated, bringing about the revolt of Catalonia; the navy was almost destroyed by the Dutch at Dunkirk in 1639; Rousillon was lost in 1642; with the battle of Rocroy (1643) departed the renown of the Spanish infantry, and the military supremacy henceforward belonged to France; Naples and Catalonia rose in revolt in 1648. In 1655 Jamaica was taken by the English. The marriage of the Infanta Maria Teresa to Louis XIV. and the peace of the Pyrenees (1659) assured to that monarch the supremacy in Spain which had formerly been exercised by Philip II. in France. After an inglorious struggle Portugal and all her colonies were lost in 1640. The reign of the childless Charles II. (1665–1700) closed the Austrian dynasty, a period of degradation surpassed only by that of the Bourbon Charles IV. a century later. Spain was considered as a prey to whichever of the great powers of Europe could lay hands on her. A brief war against France in alliance with Holland lost Franche Comté. Spain shared in the great wars of Louis XIV., but who ever else won she was always a sufferer; and the lack of a navy left her commerce and her richest colonies at the mercy of the buccaneers. A first treaty of partition of her dominions was made in 1698, followed by a second in 1700, after the death of the rightful heir, Leopold of Bavaria, in 1699. Contrary to his father's provisions, Charles left the throne to the grandson of Louis XIV. This did not avert the War of Succession (q.v.) and the losses which it occasioned. At the beginning of the 17th century the Spanish armies were the first in the world, her navy was the largest; at its close the latter was annihilated, her army was unable without assistance from Louis XIV. to establish the sovereign of her choice; population had declined from 8 to less than 6 millions, the revenue from 280 to 30 millions; not a single soldier of talent, not a statesman, remained to recall the glories of the age of Charles V. and Philip II.; the whole country grovelled in discontent at the foot of unworthy favourites raised to power by court intrigues, and dependent on a foreign prince.

The first of the Bourbon kings of Spain, Philip V. (q.v.), was proclaimed in Madrid, May 1700. He was accepted by the Cortes of Castile, but not by Aragon or Catalonia. His rival, the Archduke Charles, was supported by all the enemies of Louis XIV. The theatre of the War of Succession included Flanders, Germany, and Italy, as well as France and Spain and their colonies. In Flanders and Germany the English under Marlborough were victorious, but in Spain they fought with less success. Gibraltar was taken by Sir George Rooke in 1704, Valencia and Barcelona were occupied by Peterborough in 1705, and Philip was twice driven from Madrid. But with the aid of Berwick he won the battle of Almansa (1707), and Vendôme defeated Stanhope at Brihuega and Villaviciosa in 1710. The exhaustion of France, and the elevation of the archduke to the empire, led to the treaty of Utrecht in 1712. Catalonia submitted in 1714, and Spain was forced to adhere to the treaty, losing all her Italian possessions, Sardinia, Minorca, Gibraltar, and Flanders.

Philip V.'s first care was to alter the law of Spanish regal succession in accordance with the Salic law of France, a change productive of serious consequences later. Though during the war Philip had shown much spirit, a constitutional melancholy led him to resign his crown in 1724 to his son Louis, on whose death, after a reign of a few months, Philip resumed power. The entire government was in the hands of his second queen, Isabel Farnese, and her minister Alberoni. Their whole policy was directed to the establishment of her sons in Italy as duke of Parma and king of Naples and Sicily. In this she succeeded, but the gain was simply for the House of Bourbon; it brought no advantage to Spain. To Philip V. succeeded his son Ferdinand VI. (1746–59). His choice of ministers was good, and his avoiding war gave the country an opportunity of internal development. This led to the greater reforms of his half-brother Charles III. (1759–88). He had already been successively duke of Parma and king of Naples and Sicily, and his was the most flourishing of all the Bourbon reigns. He brought with him his Italian ministers, Grimaldi and Esquilache, who made the policy of the early part of his reign too subservient to that of France. Afterwards he gathered round him the most intelligent Spaniards of his day. Superstitiously religious though he was in private life, his reign was yet notable for the expulsion of the Jesuits in 1757, for reasons which have never been clearly explained. The years 1764–66 were marked by reforms in the administration of the colonies, where great abuses existed. Only 840,000 dollars out of a revenue of 4 millions really entered the treasury. These revenues rose shortly from 6 million to 20 million dollars for Mexico alone. His home policy was equally successful: new manufactures were established, roads were improved, more beneficial commercial treaties were made, banks were introduced, and population increased with wealth. Through fear of the movement spreading to her own colonies, Spain wisely remained neutral during the war of independence of the United States. The foreign events of the greatest importance were a fruitless expedition to Algiers in 1775, the recovery of Minorca in 1782, and the fruitless siege and blockade of Gibraltar (1779–82). The great defect of this reign was that nearly all Charles's ministers were *afrancesados;* their reforms were based rather on the theories of the French encyclopædists than on the real needs and the principles of liberty still existing in Spain. There was a wide gulf between the educated classes and the body of the nation. Charles IV. (1788–1808) retained for a short time his father's ministers; but they were soon replaced by Godoy, whose unbounded influence over Charles and his queen, limitless greed, and shameless subservience to the French, especially to Napoleon, brought the nation to the verge of ruin. He not only accumulated almost all offices in his own person, but in secret schemes with Napoleon bargained for himself half of Portugal as an independent kingdom, or a hereditary viceroyalty in America. On the outbreak of the French Revolution, in spite of ties of blood and of old treaties, Charles IV. was the last to protest against the overthrow of royalty and the execution of Louis XVI. A campaign was then begun on the Pyrenean frontier in 1793, with some success at first, changed to defeat as soon as the Republic could spare forces to turn against her southern neighbour. In 1795 the peace of Basel gained for Godoy his title of Prince of Peace; and the treaty of Ildefonso (1796) bound Spain to an offensive and defensive alliance with France against England. The result was disastrous. In 1797 Jervis won the naval battle of St Vincent; Trinidad was taken, and Cadiz bombarded. But Nelson was repulsed at Teneriffe, Puerto Rico was preserved, and the expeditions of Beresford and Whitelocke in La Plata eventually failed. The commerce and communications of Spain with her colonies was almost wholly destroyed. A scandalous quarrel between Charles IV. and his son Ferdinand (1807) augmented the hatred of the nation against Godoy. All three parties appealed to Napoleon for his arbitration and intervention. In view of the utter degradation of the crown many of the best men in Spain believed that a short rule by Napoleon might stem the tide of corruption. The royal family and the favourite attempted flight, but this was prevented by a popular outbreak at Aranjuez. Godoy was hurled from power. Charles IV. abdicated in favour of his son, Ferdinand VII., March 17, 1808. French troops entered Madrid. Charles IV., his queen, and son Ferdinand, with Godoy, were summoned to Bayonne. There the crown was renounced by Ferdinand in favour of his father, who in turn ceded it to Napoleon. But on May 2 an unsuccessful outbreak in Madrid had begun the war of liberation, and Napoleon had to face a nation in arms. June 6, Joseph Bonaparte was proclaimed king of Spain. Nominally he reigned till 1813, but the Juntas, the representatives of the nation, acknowledged only the captive Ferdinand VII. For details of the French occupation of Spain, their forcible expulsion by Spanish, Portuguese, and English, see MOORE, WELLINGTON, PENINSULAR WAR, &c. While these operations were going on, the patriots were making great efforts to reform the government, and to give more real liberty to the people. The task was difficult; the absolutist party was still strong, and the liberals were divided; but the Constitution of Cadiz of 1812 is really the commencement of modern Spain. When Ferdinand returned in March 1814, he found the absolutists still powerful enough to enable him to reject the constitution to which he had sworn, to re-establish the Inquisition, and to remove all restrictions to his rule. An insurrection headed by Riego and Quiroga forced him to accept the Constitution from 1820 to 1823, but through the mistakes of the liberals, with the aid of 100,000 French soldiers under the Duc d'Aumale, he regained his authority, and remained absolute master till his death. In December 1829 the childless Ferdinand married his fourth wife, Christina of Naples. Up to this time his brother, Don Carlos, had been considered heir. In prospect of issue, Ferdinand promulgated (March 31, 1830) the pragmatic law of Charles IV., 1789, restoring the old law of Spanish succession. In September 1832 he revoked this sanction, but again recalled his revocation. Don Carlos was exiled to Portugal. April 4, 1833, Cortes acknowledged Ferdinand's daughter Isabella as heir to the throne, with her mother as regent. Ferdinand died 29th September 1833. During his reign the whole of Spanish continental America was lost (see AMERICA, Vol. I. p. 224, PERU, &c.), and of all the vast colonies there remained only Cuba, Porto Rico, the Philippine, Caroline, and Mariana islands, Fernando Po, the Canaries, and a few ports and towns in Africa and the Straits. The opinion of Europe, which in 1823 had been conservative, and had enabled Ferdinand to regain absolutism by French help, had in 1833–40 become liberal, and this, with English help far more than the skill of her own armies, enabled Christina to vanquish Don Carlos; but her government was far from strong, revolts and *pronunciamientos*, both by liberals and conservatives, were continually occurring. Monks were massacred in Madrid and Catalonia in 1834–35; church property was confiscated. The constitution of 1812, enlarged in 1836, was sworn by Isabella on attaining her majority in 1843. The marriage of the queen to her cousin, Francisco de Assisi, and of her sister to the Duc de Montpensier, only weakened her position. Successive ministries rose or fell from power, all inefficient or corrupt. Narvaez in 1844 showed some energy. O'Donnell conducted successfully a campaign in Morocco in 1859-60. On the whole, liberalism advanced; republicanism appeared after 1848. In disgust at corrupt administration the country accepted a *pronunciamiento* by Prim and Topete at Cadiz in 1868. Isabella fled to France, and there resigned in favour of her son, Alfonso XII. The programme of the military leaders was simply destructive. A provisional government of two years (the chief event of which was to furnish the pretext for the Franco-German war of 1870) ended in the choice of Amadeus (q.v.) of Savoy as king. In 1873 he resigned the crown. The republic which followed showed the wide differences between the Federalists and the conservative Republicans. This occasioned the second Carlist war, 1872-76 (see CARLISTS). On the waning of their cause, Isabella's son, Alfonso XII., was proclaimed king, 29th December 1874. February 27, 1876, Don Carlos withdrew to France. Mainly through the talents of his minister, Cánovas del Castillo, Alfonso's reign of eleven years (1874-85) was a time of relative prosperity and improvement, and enabled his queen Christina quietly to succeed as regent for his posthumous son, Alfonso XIII., born 17th May 1886. Since then the liberals have returned to power, and changes of ministry are no longer marked by bloodshed or exile. The queen-regent is personally respected; but both Carlists and Republicans still agitate. The constitution embraces all modern liberties. Since the last Carlist war Spain for the first time is under one legal rule; but whether liberal or conservative, the ministries are chosen by corruption and intrigue rather than by any honest expression of the popular will, and the future of Spain is still in doubt.

REGNAL YEARS OF SPANISH KINGS SINCE THE UNION OF ARAGON AND CASTILE:

Isabella and Ferdinand (los reyes Católicos)	1474
Joana and Philip I. (Austrian dynasty)	1504
Charles I.	1516
Philip II.	1556
Philip III.	1598
Philip IV.	1621
Charles II.	1665
Philip V. (Bourbon dynasty), grandson of Louis XIV.	1700
Luis I., a few months; Philip V. resumed same year.	1724
Ferdinand VI.	1746
Charles III.	1759
Charles IV.	1788
Ferdinand VII.	1808
Joseph Bonaparte	1808-13
Isabella II.	1833; abdicated, 1868
Provisional Government	1868-70
Amadeus I. of Savoy	1870-73
Republic	1873-74
Alfonso XII.	1874-85
Queen Christina regent	
Alfonso XIII.	born 17th May 1886

There is no good general history of Spain. The new *Historia General*, now in course of publication in detached portions by members of the Academy of History, is not sufficiently advanced to pronounce upon. The introductory volume of Bibliography, by Menendez y Pelayo, will almost certainly be valuable when published. In addition to the works named under more special headings, we may mention M. M. Siret, *Les Premiers Âges du Metal dans le Sud-Est de l'Espagne* (Antwerp, 1887); Hübner's *La Arqueologia de España* (Barcelona, 1888). In mediæval Spain Schirrmacher's *Geschichte Castiliens, 12 und 13 Jahrh.* (Gotha, 1881), and *Geschichte Spaniens im 14 Jahrh.* (Gotha, 1890), with a volume to follow, will lead up to Prescott's works. The reign of Philip II. has attracted numerous recent writers. Ferrer del Río's *Historia del Reinado de Carlos III. en España* (4 vols.) is good. The *España Sagrada* (51 vols.) is a useful collection, chiefly for ecclesiastical events. The Academy of History in its *Boletin* and *Memorias* has valuable materials. Colmeiro's *Introduccion* to the *Cortes de Leon y Castilla* (2 vols. Madrid, 1883) and Cárdenas' *Ensayo sobre le Historia de la Propiedad Territorial en España* (2 tomos, Madrid, 1873), besides the *cronicas* and contemporary writers of each period, will be found worth consulting. See also ARAGON, NAVARRE, &c.

SPANISH LANGUAGE AND LITERATURE.—Three Romance Languages (q.v.) are still spoken in Spain: the Castilian, generally known as Spanish; the Catalan, a dialect of Provençal; and the Galician, closely allied to Portuguese. Castilian, which has been deservedly called 'the noblest daughter of Latin,' is spoken, with slight local variations, by more than two-thirds of the population. The reason for its having to a great degree supplanted Catalan and Galician is to be found quite as much in political causes as in its own richness of vocabulary and stately measured cadence. Its chief characteristics are the purity of its vowel-sounds and the strong guttural, the origin of which is doubtful, though its introduction is undoubtedly modern. The Castilian vocabulary contains a large number of Arabic words, chiefly connected with agriculture or science; Greek words, mostly of learned and modern introduction; the traces of Basque and Gothic are slight. The influence of French is very noticeable, particularly during the 18th and 19th centuries. Castilian is the form of Spanish spoken in Mexico, Central America, South America (excepting Brazil), Cuba, Puerto Rico, and the other Spanish colonies.

See on the subject generally, Grober, *Grundriss der Romanischen Philologie*; Diez, *Grammaire des Langues Romaines* (Fr. trans.); the admirable article by Alfred Morel Fatio in the *Encyclopædia Britannica*; the Dictionary of the Spanish Academy (1st ed. 1726); the Spanish-English dictionaries by Neumann and Baretti, Velasquez, Garnier. Grammars—Wiggers, *Grammatik der Spanischen Sprache* (Leip. 1884); Knapp, *Spanish Grammar* (Boston, 1887); *Simplified Grammar*, by the present writer (1892). For Catalan, Milá y Fontanals, *Estudios de la Lengua Catalana*. For Galician, Arce, *Gramática Gallega* (Lugo, 1868).

Castilian Literature.—The earliest existing documents in Spanish belong to the first half of the 12th century. The first monuments of Spanish literature are poetical. The *Poema del Cid* (see CID), ascribed to the later half of the 12th century, is a typical *chanson de geste*; picturesque and spirited at times, it breathes the spirit of the turbulent age which produced it. Written in unformed and uncouth language, it displays a barbarous and irregular versification. The lines vary in length from twelve to sixteen syllables, and the same rhyme is carried on through long passages. To the 13th century belongs a body of religious poetry of tame character and slight merit. Gonzalo de Berceo is the first Spanish author whose name has come down to us. He wrote rhyming lives of saints and praises of the Virgin, which closely resemble in style, subject, and versification those of other monkish authors of his own and the succeeding century. The 13th century saw the formation of literary Castilian. To this period belongs Alfonso the Wise, king of Castile (see ALFONSO X.), who left behind him a large and valuable body of works written either by himself or at his direction. The most important of these is the code of laws, with digressions on moral and political philosophy, known as *Las Siete Partidas*. This treatise, embodying anterior Gothic codes, has been the groundwork of all subsequent Spanish legislation; it forms also a most important monument of the language, which now for the first time appears as an instrument fitted for literary production. A collection of verse, mostly of a religious character, and undoubtedly belonging to this period, has been long a puzzle to scholars from the circumstance that, appearing as the work of Alfonso the Wise, it is written in the Galician dialect. Alfonso's literary tastes were shared by his nephew, Don Juan Manuel, author of several works of great interest which have come down to us, and of many others now unfortunately lost. He is best known by the *Conde Lucanor* or *Libro de Patronio*, a series of stories mostly of eastern origin, loosely connected together and with rhymed morals attached. The most original writer of the 14th century is Juan Ruiz, archpriest of Hita, a disreputable cleric, who relates his love adventures in poetical form, interlarding them quaintly with moral fables and religious hymns. In spite of great blemishes and frequently recurring obscene and blasphemous passages, the work is valuable from its vivacity and the excellent picture it gives of one side of life at the time. The verse is still that of the earlier poets, fourteen syllable lines, stanzas of four lines with one rhyme repeated. In prose these early centuries produced little that is worthy of note, as Latin was still much used. By the direction and, probably, under the supervision of Alfonso the Wise, was compiled the *Grande y General Historia*, extending from the creation nearly to his own times. This work was continued by official chroniclers, generally as a bare record of events, down to the time of Ferdinand and Isabella. Pedro Lopez de Ayala wrote the history of the kings under whom he lived in somewhat more picturesque and lively style than his predecessors; his *Rimado de Palacio* is a caricature of the different classes of society of his time, for studying which his high position and many adventures gave him admirable opportunities.

In the 15th century two new and important branches of Spanish literature appear—the Romances of Chivalry (*Libros de Caballerias*) and Ballads (*Romances*). The *Amadis de Gaula* (see AMADIS), first and best of books of chivalry, has come down to us in a translation from a Portuguese version, of which the original is lost. It is, however, certain that this is not the earliest form of the story in Spanish. The *Amadis* is not free from the exaggerations and stilted style that deface later books of its class, but, unlike them, it contains passages of great beauty, and, in spite of its being a translation, its language is generally dignified and pure. The popularity of the class was great; but successive authors rivalled one another in wild exaggeration and the frigid impossibility of the adventures of their heroes, who live under social conditions that have never existed, and in a world without geography. The Romance of Chivalry was dying a natural death when Cervantes gave it the *coup de grâce*. The origin of the Spanish ballads is very uncertain; they are probably of indigenous growth, as no striking parallels can be cited to support the theory that they are imitated from the poetry of the Moorish conquerors of Spain. The great mass of them was collected in the 16th and 17th centuries from the mouths of the people, but many of them are of much earlier date. Handed down orally from generation to generation, they underwent considerable modification, and their language alone cannot be taken as a sufficient clue to their date. Their structure is characteristically Spanish; the lines may be considered either as octosyllabic or as of sixteen syllables with cæsura; the same *asonante* or vowel-rhyme is continued throughout whole compositions. In subject these ballads range from sacred history to the Arthurian and Carolingian cycles, but the most valuable and interesting are those which celebrate the national heroes and the Moorish champions against whom they fought.

Thus far the works mentioned have been of purely national character or derived from sources common to the writers of the middle ages; but at the court of John II. the influence of Provençal literature began to make itself strongly felt, and a generation of stilted and affected poetasters arose encouraged by the king, who formed one of their number. The works of many authors of this school are collected in the celebrated *Cancionero de Baena*; with the exception of a few religious pieces they are of slight merit, but they succeeded in enriching Spanish with new lyric metres. At the end of the 15th century appeared the *Tragicomedia de Calisto y Melibea*, better known as the *Celestina*. It is said to be the work of two authors, but the wonderful evenness of its style makes this hard to believe. The *Celestina* partakes of the nature of novel and drama. Written entirely in dialogue, but at the same time immoderately long and unsuited for dramatic representation, it is unique amongst works of its time and country, being perfectly unaffected in style. Taking its subject from a side of life that must have been familiar to its authors, it neither shirks nor courts obscene details, but aims at and thoroughly succeeds in giving a true and animated picture, and at the same time enforcing a moral lesson. It soon became one of the most popular books in Spain, and was translated into most European languages.

It is probable that from Roman times the Drama (q.v.) never became extinct in Spain. It is mentioned in the *Siete Partidas*, and one of the earliest extant pieces of Spanish is a miracle-play, *El Misterio de los Reyes Magos*. The modern Spanish drama, however, must reckon its origin from the end of the 15th century, when Juan del Encina wrote *églogas* or *representaciones* of pastoral character, some of which were undoubtedly acted. Gil Vicente and Torres Naharro imitated and improved upon the methods of Encina, but Lope de Rueda, playwright and actor (fl. 1550), must be considered as the father of the Spanish dramatists, and as such he is mentioned by Cervantes. Continuing the pastoral drama of his predecessors, Rueda also wrote regular plays, divided into acts. In these the influence of the Latin stage is perceptible. The best part of Rueda's work consists of his spirited interludes (*entremeses, loas*) of a popular and burlesque character. Cervantes (q.v.) commenced his career as a dramatic author, but his two earlier pieces, *La Numancia* and *El Trato de Argel*, though finely conceived, were unsuccessful.

With the decay of the popularity of the romances of chivalry is coincident the rise of the novel in its different forms. In the *Diana Enamorada*, Montemayor and Gil Polo directly imitated the Italian. Cervantes and Lope de Vega each produced a novel of the kind, but the false and exaggerated sentiment and inferior verse to which the impossible shepherds generally treat one another in these compositions make it hard to understand the popularity which they undoubtedly enjoyed. Side by side with the pastoral novel, but with stronger growth, throve the realistic *novela picaresca*, or rogue's story (see NOVELS), subsequently brought to perfection by Le Sage, who in his *Gil Blas* drew largely upon his Spanish models. The earliest book of the kind is *Lazarillo de Tormés*, ascribed, apparently without reason, to Diego Hurtado de Mendoza (see MENDOZA), a poet and historian of the time of Charles V., at whose court he played a considerable part. Lazarillo, the hero, like his brethren of the other books of the class, is a poor boy of shady antecedents, who, by his own ingenuity and unscrupulousness, with varying fortune pushes his way, generally as a servant, amongst all classes of society. So admirable a vehicle for amusement and satire was not neglected, and *Guzmán de Alfarache*, *Marcos de Obregón*, *La Picara Justina*, and many others go to prove the popularity of this kind of story. A solitary and not very brilliant example of the historical novel at an early date is the *Guerras de Granada* by Hita.

Some of the older poets, amongst them the Marqués de Santillana, had imitated Italian models, but the influence of Petrarch and his school is most directly felt in Juan Boscán and Garcilaso de la Vega, who flourished in the first half of the 16th century. The latter in his *églogas* brought hendecasyllables to perfection in Spanish, and left at his early death a small collection of the most beautiful poetry in the language. An imitator of, and at times a translator from, Virgil and Petrarch, he is not unworthy of his models; the harmony of his verse is unsurpassed, unless it be by the *Coplas de Manrique*, probably one of the finest elegies extant.

Lyric poetry reached its culmination in the first half of the 16th century. Most of it is of religious character. In sublimity of conception and perfection of execution Herrera's (see HERRERA) odes and elegies are entitled to a very high place in European literature. Whilst Herrera sang of the victories and reverses of his time, Luis de León drew his inspiration from nature, solitude, and religious meditation. Sweetness of language never deserts him, but his productions are uneven in merit. The brothers Argensola (q.v.) owe their fame rather to good taste than to poetic inspiration. These writers come within the Spanish golden age, during which prose reached its highest development in the religious and mystic writings of Luis de León, Luis de Granada, St Teresa, and Juan de la Cruz, in the histories of Mariana (q.v.) and Solis, and in parts of the writings of Cervantes (see CERVANTES). The *Don Quixote*, with its quaint humour, rollicking fun, melancholy touches, and profound views of human nature, is deservedly, both at home and abroad, the best-known and best-loved book in Spanish. Unique amongst the works of its time, and far superior to the other efforts of its author, it belongs to no class, and has no successor in Spanish or any other literature. Cervantes' other works, the *Galatea*, *Persiles y Segismunda*, *Viage del Parnaso*, dramatic works and novels, are read chiefly on account of the interest which must be felt for the author of *Don Quixote*.

Contemporary with Cervantes was Lope de Vega (see VEGA), the idol of his time, the 'prodigy of nature' (*monstruo de la naturaleza*), as he was called on account of the immense mass and great variety of his writings. Almost every branch of literature was familiar to him. Of dramas alone he wrote over 2000, besides a great body of lyric verse, epic and mock epic, novels both pastoral and of adventures, and criticisms. It is by his dramas that he is best known, and especially by those of cloak and sword (*capa y espada*). These within certain well-defined limits afford considerable scope for variety. The scene is invariably laid in some Spanish town. The principal characters are two lovers, whose adventures and somewhat stilted dialogue are parodied and relieved by those of their servants, one of whom is generally the *gracioso* or buffoon, whose homely pleasantries sometimes jar disagreeably in the midst of fine and solemn passages. The metre of the Spanish drama is generally the same as that of the ballads; some variety, however, both of grouping of rhymes and of metre is admitted. A distinctive feature is the exceeding intricacy of the plots. This characteristic is so marked as to have led several critics to believe that a Spanish drama requires a Spanish audience to follow it intelligently. The great amount of the productions of Lope de Vega precluded all attempt at finish. His verse, however, is always flowing, and he generally attains success by thoroughly carrying out his own maxim that the drama is a purely popular form of literature, and that the only critics to be regarded are the mass of those who pay their money at the theatre-door. Calderón de la Barca (see CALDERON) outlived the golden age of the drama of his country. More philosophic, careful, and with a higher ideal than Lope, he is generally incapable of carrying out his gigantic enterprises, and is, broadly speaking, a poet of fine passages rather than a dramatic author of high merit. In attempting sublimity he frequently becomes bombastic and misty, and is deeply infected with the bad taste of his time. He perfected the *auto sacramental*, a religious play, or rather a dramatised theological discussion, in which such characters as Conscience, Free-will, Hope, and the cardinal virtues take part. On these, to modern taste, somewhat dull compositions, in which Christian theology is frequently jumbled up with pagan mythology, Calderón lavished a great deal of his best verse, and to them his reputation amongst his contemporaries was largely due. Equal to Lope or Calderón as dramatists, though inferior as poets, are Tirso de Molina (see TELLEZ) and Moreto. The former handled to perfection his native language, and is, more than any other, characteristically a Spaniard of his time. His defects are the want of a high ideal and the frequent coarseness of his language. Outside his own country he is chiefly known as the author who first dramatised the story of Don Juan Tenorio, the *Burlador de Sevilla*, a theme whose impressive nature he well knew how to take advantage of. Moreto is the most correct of Spanish dramatists, and his *Desdén con désden* merits special mention, even in an age which produced, besides the authors already mentioned, Rojas and Alarcón (q.v.). The number of dramas produced at this time is almost incredible, and some, even of the anonymous ones, are such as in a less fertile age would have sufficed to found a reputation.

Spanish eloquence has always had a tendency to become bombastic; mannerisms and affectation of the worst kind have been mistaken for cultured style; extravagance of metaphor was rife even at the best period (see EUPHUISM); but when literature began to decay all these defects became more marked. The typical representative of this *culto* school is Luis de Góngora (see GONGORA), a poet who enjoyed great popularity in the golden age, and whose example probably did much to hasten a climax which had already become inevitable. In his youth he wrote simply and correctly short lyric pieces of great beauty. It is difficult to believe that this is the same Góngora who, a few years later, produced the *Soledades* and *Polyfemo*, poems so obscure, bombastic, and crammed with *concetti* that before his death they required lengthy commentaries. Amongst those who protested against the tendency of the times, whilst frequently allowing themselves to be carried away by it, was Francisco de Quevedo y Villegas (see QUEVEDO), the bitter satirist and writer of trenchant verse. Extremely versatile, his writings include erotic verse, light lyrics, essays on government, picaresque novels, and theological discussions. In his merits and defects he closely resembles Swift. The best known of his works are his *sueños*, or visions, in which the motives and manners of his time are held up to ridicule with a masterly and unsparing hand.

At the end of the 17th century the sun of Spanish glory set, and with it the sun of Spanish literature, so suddenly and completely as not to leave an afterglow behind it. Of the succeeding century only a few names deserve mention. Padre Isla (q.v.) in *Fray Gerundio* ridiculed the low ebb of education, and particularly of pulpit oratory, with wit and good sense worthy of a better age. Samaniego and Yriarte wrote some clever fables in the style of the inimitable Lafontaine. The Academy, founded during the first half of the 18th century, produced the magnificent dictionary which is its chief claim to the gratitude of scholars. When literature seemed at its lowest ebb, and nothing found favour unless slavishly imitated from the French, Moratin (q.v.) came to add one more name to the glorious list of dramatists.

The war of independence roused the Spaniards from the seemingly hopeless state of lethargy into which they had sunk. In lyric poetry Quintana and the Duque de Rivas attached themselves to the classical school, whilst the influence of Byron pervades the noble verse of Espronceda, whose successors are Zorrilla, Nuñez de Arce, and Campoamor. Historians, critics, and scholars like Juan Valera, Menendez Pelayo, Pascual de Gayangos, and Cánovas del Castillo worthily carry on the work commenced by Sanchez and Sarmiento. The drama flourishes, though still overshadowed by the French. The novel is, however, the department in which most progress has been made. In the early part of the 19th century Fernán Caballero (q.v.) and Trueba left the old and worn-out track, and drew their inspiration and characters from the people of their own country and age. At the present time Spain possesses novelists worthy to rank with those of any other European country. Juan Valera's *Pepita Jimenez* is one of the best novels of the century. Pereda writes delightfully of his northern mountains. Emilia Pardo Bazán thoroughly understands her own people and time. Names like those of Alarcón, Perez Galdos, and Palacio Valdés have only to be better known to secure their possessors a wide appreciation outside their own country. History is occupied chiefly in the collection of materials, and many valuable monographs have been published. As a historian of his country the name of Modesto Lafuente must not be forgotten. Periodical literature of a not very high order is abundant. Signs of literary activity are visible in South America, but as yet no work worthy of separate mention has appeared.

Catalan Literature.—The intercourse between Catalonia and Provence has been great from the earliest times. The troubadours of Provence carried with them across the Pyrenees their own language as well as their own poetical forms. Their influence may be seen in the works of Raymond Lully, whose poem 'Despair' (*Lo Desconort*) is deeply impregnated with their mannerisms. At the later end of the 14th century a consistory of the *gay saber* was founded at Barcelona in imitation of the one already existing at Toulouse. From this may be dated the partial emancipation of Catalan verse. Two Valencian poets distinguished themselves in their native language. Ausias March, whose songs of love and songs of death are fine in spite of intentional obscurity, and Jaume Roig, whose bitter satire, *The Ladies' Book*, is supposed to contain details of his own life. Roig died in 1478, and at the union of Castile and Aragon Catalan sank to the position of a dialect. In prose the principal monuments of old Catalan are the works of Lully, including the interesting *Book of the Order of Knighthood;* the *Chronicles*, some of which are interesting both in matter and manner, especially that of Ramón Muntaner; and one romance of chivalry entitled *Tirant lo Blanch*, an exaggerated example of the defects of the class. In the 19th century Catalan verse has been revived, probably owing to the jealousy that has always existed between Madrid and Barcelona. This revival is largely owing to Jacinto Verdaguer, some of whose verse in archaic language is really charming and natural. In the Galician, which has never been a literary language, few books exist, with the exception of collections of popular songs.

Spa'lato, or less usually Spalatro (Slav. *Split*), the busiest town of Dalmatia, stands on a promontory on the east side of the Adriatic, 160 miles SE. of Fiume. Here in a most beautiful situation the Emperor Diocletian built for himself a colossal palace (*Salonæ Palatium*, whence perhaps Spalato, though more probably from *'s παλάτιον*), to which he retired when he abdicated the throne in 305. The palace faced the sea, looking southwards; its walls were from 570 to 700 feet long and 50 to 70 feet high, and enclosed an area of 9½ acres. It stood square like a Roman camp, and had a gate in the middle of each side, and was of the most solid construction. Architecturally it is of the highest interest in that it contains several features that presage the architectural styles and devices of modern times. Inside the palace the roads connecting the gates crossed at right angles in the middle, and two of the four courts thus formed were each occupied by a temple (or similar building), one to Æsculapius, the other to Jupiter. So at least says an ancient tradition, though some modern authorities claim the latter, and others the former, as the mausoleum of the emperor. The temple of Jupiter is externally an octagon with a colonnaded peristyle and internally a circle covered by a dome. Where the projecting portico was built there now stands a tower built in the 14th and 15th centuries, thoroughly restored in 1891–92. Since the year 650 this temple has been a Christian cathedral; it contains a magnificent marble pulpit. The interior was extensively restored in the years immediately preceding 1885. The other temple is used as a baptistery; it is of small size and rectangular in shape. All the interior buildings and nearly all the exterior walls of this gigantic palace are still standing in a fairly good state of preservation. But the interior was converted into a town in 639 by the citizens of Savona (q.v.) who escaped the destruction of their town by the Avars, and it has been occupied ever since. The existing city of Spalato lies, more than half of it, outside the palace walls. It contains a museum rich in the remains of Savona, and has a lively trade in wine, cattle, &c., being one of the principal ports for Bosnia and Herzegovina. Its industries embrace the manufacture of liqueurs (rosoglio and maraschino), bricks, ropes, &c. Pop. 14,513. See Roman Architecture; Freeman's *Historical Essays* (3d series, 1879); and T. G. Jackson's *Dalmatia* (vol. ii. 1887).

Spalding, a Dutch-looking town on the Welland in Lincolnshire, 14 miles SW. of Boston, with a fine church (Decorated and Perpendicular), built in 1284 and restored by Sir G. Scott, who also planned two of the remaining three churches in the town. The grammar-school, of which Bentley was master in 1682, was founded in 1568; new school buildings were erected in 1881. Ayscoughfee Hall, dating originally from 1420, was the residence of the antiquary Maurice Johnson, who helped to found the Society of Antiquaries and the Spalding Gentlemen's Society (1710; resuscitated in 1889). This town had a castle and a monastery prior to the Conquest. The latter eventually became a priory (1051), attached as a cell to Crowland; the ruins of the chapel (1300) at Wykeham (3 miles from Spalding) belonged to a country-house of the priors. The river is navigable up to this town for vessels of 70 tons. Spalding is an important railway centre, and has an active trade in the agricultural produce of the fertile fens. Pop. (1851) 7627; (1891) 9014. See *Sat. Rev.* (July 22, 1882).

Spalding, John (fl. 1624–45), was the commissary clerk of Aberdeen and diarist, after whom is named a well-known northern Book-club (q.v.).

Spallanzani, Lazaro, naturalist and traveller, was born at Scandiano, in the duchy of Modena, Italy, on 12th January 1729. After studying, at Reggio di Modena and Bologna, natural science, mathematics, the classical tongues, law, and other subjects, he was in 1754 appointed to the chair of Logic, Metaphysics, and Greek at Reggio, and soon afterwards was transferred to Modena. But he took the greatest interest in natural history and physiological questions. Amongst other things his attention was directed to the doctrine of spontaneous generation propounded by Needham and Buffon, which after careful study and experiment he overturned. On the re-establishment of the university of Pavia Spallanzani was appointed (1768) professor of Natural History and keeper of the museum, which he greatly enriched with fishes, crustacea, and testacea, the fruits of his numerous excursions. In 1785-86 he spent nearly a twelvemonth in Turkey engaged in scientific observation, and during the year 1788 visited Naples whilst Vesuvius was in eruption, the Lipari Isles, and Sicily, and wrote an account of his inquiries, *Viaggi alle due Sicilie* (6 vols. 1792). He died of apoplexy, 11th February 1799. In *Dissertationi de Fisica Animale e Vegetale* (2 vols. 1780) he clearly demonstrated the true physiological nature of digestion, and established, on the basis of experiment, the respective functions of the spermatozoa and the ovum in reproduction.

Span, a measure of length, being the distance between the tips of the thumb and little finger when the fingers are expanded to their fullest extent. This space averages about 9 inches, which accordingly is the fixed measure given to the span.

Spandau, a town and first-class fortress of Prussia, is situated at the confluence of the Havel and the Spree, 8 miles by rail W. by N. of Berlin. The principal defence of the capital on that side, it has very strong modern fortifications, including a citadel. In the 'Julius tower' of this structure is preserved in gold the 'Reichskriegsschatz' of £6,000,000 that the government, according to a law of 11th November 1871, keep in reserve for a great war. Spandau is the seat of large government cannon-foundries, factories for making gunpowder and other munitions of war, and has an arsenal. Pop. (1875) 27,630; (1890) 44,611, including a garrison of nearly 4000 men. Spandau, one of the oldest towns of Brandenburg, was a favourite residence of the electors. It surrendered to the Swedes in 1634, to the French in 1806, and in 1813 to the Prussians.

Spanheim, Friedrich, theologian, was born at Amberg, January 1, 1600; studied at Heidelberg and Geneva; visited Paris and England; was appointed in 1631 to the chair of Theology at Geneva, in 1641 at Leyden; and died there, April 30, 1648. He contributed to the controversy with Amyraut *Disputatio de gratia universali* (1644), &c.—Ezechiel Spanheim, son of the foregoing, was born at Geneva, 7th December 1629, studied at Leyden, and was appointed professor of Rhetoric there in 1651. He next became tutor to the sons of the Elector Palatine, and with them travelled in Italy and Sicily. In 1665 he represented the Palatinate and Brandenburg as resident in England; in 1680 he went for nine years to Paris as ambassador extraordinary. He took part in the peace of Ryswick, later went on missions both to Paris and London, and died at the latter, 7th November 1710. He had great learning in the history of ancient law and in numismatics, and his *Dissertationes de usu et præstantia numismatum antiquorum* (best ed. 1706-16) and *Orbis Romanus* (1704) made his name widely known.—Friedrich Spanheim, his brother, was born at Geneva, May 1, 1632, studied at Leyden, was appointed to the chair of Theology at Heidelberg in 1655, at Leyden in 1670, and died there, May 8, 1701. He defended Calvinism against Descartes and Cocceius. His collected works fill 3 volumes (1701-3).

Spaniel, one of the longest established breeds of dogs. Dr Caius gives a description of the spaniel in his treatise *Of Englishe Dogges* (1576). The working spaniel may be divided into the Clumber, the Sussex, and the Field Spaniel. The clumber derives his name from the estate of the Duke of Newcastle, who originally imported them from the kennel of the Duc de Noailles, and bred them for many years at Clumber Castle (q.v.). The pure breed was guarded with such jealousy that until recent years it was difficult to obtain a pure clumber. Clumbers are usually worked in a team of four or five; as they generally hunt in silence, they are extremely useful in thick cover, the game not being alarmed without cause. In appearance the clumber is a handsome lemon and white dog, short in the leg, long in body, coat like a setter, a massive head with large drooping ears.

The Sussex is also a variety of long standing, though the pure breed was only resuscitated in 1870 with great difficulty. In colour the Sussex should be a 'golden-liver' or brown, otherwise it closely resembles the clumber.

The Black Spaniel is gradually becoming the commonest, as it is certainly the handsomest variety of field spaniel; it is bred mainly from Sussex blood. The 'cocker' and the 'springer' are names indiscriminately applied to field spaniels of unknown breeding; they are generally liver and white, and are probably cross-bred Sussex.

Though there are records of the existence of an English water-spaniel, yet the breed has been entirely eclipsed by the Irish water-spaniel, a variety maintained in purity through the efforts of the late Mr Justin M'Carthy. The Irish dog resembles a large poodle in face and size, an untrimmed coat curling all over the body; in colour it should be a reddish liver.

Toy Spaniels, though identical in name, have little in common with the working spaniel. They are divided into the black-and-tan King Charles, first brought into notice by Charles II., and the red and white Blenheim, established by the Duke of Marlborough. The toy spaniel should not weigh more than 10 lb., and should have a short turned-up face like a pug-dog. From their long coats and small size these dogs are only fitted for pets, but are bright and cheery in disposition.

Spanish Fly. See Cantharides.

Spanish Legion. See Evans (De Lacy).

Spanish Main (i.e. *main-land*), a name given to the north coast of South America from the Orinoco to Darien, and to the shores of the former Central American provinces of Spain contiguous to the Caribbean Sea. The name, however, is often popularly applied Caribbean Sea itself, and in this sense occurs frequently in connection with the Buccaneers (q.v.).

Spanish Marriages. See Guizot.

Spanish Town. See Jamaica.

Spar (Ger. *Spath*), a term applied by miners to any bright crystalline mineral, and adopted by mineralogists in the names of a number of minerals

—calcareous spar, Fluor Spar (q.v.), &c.—in which, however, it has no proper generic significance.

Sparks, Jared, American historian, was born at Willington, Connecticut, May 10, 1789, graduated at Harvard University in 1815, and became tutor in mathematics and natural philosophy there, and one of the conductors of the *North American Review*. In 1819 he was settled as a Unitarian minister at Baltimore, where he wrote *Letters on the Ministry, Ritual, and Doctrines of the Protestant Episcopal Church*. In 1821–23 he edited the *Unitarian Miscellany*, in which he first published his *Letters on the Comparative Moral Tendency of Trinitarian and Unitarian Doctrines*. In 1821 he was chosen chaplain to congress, but two years later he abandoned preaching owing to ill-health, and for seven years was proprietor and editor of the *North American Review*. In 1828 he published a *Life of John Ledyard*, and from 1834 to 1837 edited at Boston 12 volumes of the *Writings of George Washington*. This important national work was followed by the *Diplomatic Correspondence of the American Revolution* (12 vols. 1829–30), and the *Life of Gouverneur Morris* (3 vols. 1832). At this period he commenced the *American Almanac*, and began also his *Library of American Biography*, first issued in two series of 10 and 15 vols. In 1836–40 was published his collection of the *Works of Benjamin Franklin* (10 vols.), and in 1853 his *Correspondence of the American Revolution* (3 vols.). Besides these multifarious literary labours, combining laborious research with clear arrangement, a simple style, and accurate statement, he was from 1839 to 1849 McLean professor of History at Harvard, and from 1849 to 1853 president of the college. He died March 14, 1866. See memoirs by Brantz Mayer (1867) and G. E. Ellis (1869).

Sparling. See SMELT.

Sparrow (*Passer* or *Pyrgita*), a genus of birds of the family Fringillidæ, having a strong conical bill, the upper mandible slightly curved, the lower mandible compressed and shorter than the upper, the nostrils partly concealed by the short feathers at the base of the bill, the legs moderately long and stout, the claws sharp and curved, the tail moderately long, and nearly even at the tip. The species are not very numerous, and are exclusively found in the Old World. The Common Sparrow, or House-sparrow (*P. domesticus*), is plentiful almost everywhere in the British Islands, its distribution following cultivation even to the Outer Hebrides. It is found also throughout Europe as far as to the Arctic Circle, but not in the Faroes, abounding particularly in the northern countries, from which its range extends eastwards into Siberia, and southwards in Africa to Lake Albert Nyanza, Morocco, and Madeira. A paler variety is found in Siam, Burma, and the Indian region as far west as southern Persia. Of all British birds the sparrow is the boldest in its approaches to man, and it is too well known to require description. Town sparrows are not mere visitors from the neighbouring country, but constant inhabitants of the town itself, with the smoke of which their plumage is begrimed. The sparrow in its best plumage is not a very beautiful bird, nor so elegant in form as many others of the finch tribe; it has no melodious song, but its habits are interesting, and its frequent lively chirp is pleasing. Sparrows often congregate in great flocks, particularly in autumn. The sparrow is one of the most omnivorous of birds, devouring animal and vegetable food indiscriminately, and eating vast numbers of insects and their larvæ during summer. Their depredations on crops have induced many farmers to use means for their destruction. They are good to eat, though little used for this purpose in Britain. It is otherwise in France, where all the small birds are sought after as articles of food. But the destruction of sparrows may be carried too far; and in France it has been followed by an increase of caterpillars, vastly more injurious to crops than the sparrows themselves. Since the young are fed upon caterpillars and insect larvæ, the killing of the fledged young has been recommended as the best method of taking advantage of the usefulness of the sparrow and at the same time checking its autumn ravages among the grain. The sparrow makes a very inartificial nest, collecting a quantity of hay or some similar material, in a hole of a wall, and lining it with feathers; sometimes, but more rarely, building a rude dome-shaped nest in the higher branches of a tree. Apart from the habitations of man, which it so much frequents, it often builds in crevices of rocks, or in cliffs on the seacoast, or under the shelter of the nests of rooks, one rook's nest sometimes covering several nests of sparrows. Several broods are produced in succession, and the breeding season is prolonged over the whole summer, one brood succeeding another. In summer the plumage of the sparrow is more brilliant than in winter, and the female is of more sober plumage than the male, exhibiting indeed almost no variety of colour. In Italy a species, *P. italiæ*, is found; and in Sardinia, Sicily, and Malta another species, *P. hispaniolus*, occurs, which in Spain breeds in the woods, while the common sparrow keeps to the towns. About 1862 the house-sparrow was introduced into the United States, and it has also been acclimatised in Australia and New Zealand, in all which places it has become a great pest. The Tree-sparrow (*P. montanus*), the only other British species, is very similar to the common sparrow, but of rather smaller size; rarer and more local, but extending in its range, being found in the Hebrides and St Kilda, very sparingly in the south-west of England, and resident in Ireland near Dublin. It is multiplying in the Faroes, and extends beyond the Arctic Circle. It is more abundant in some parts of Europe than the house-sparrow. It visits Egypt and Arabia, and is found in the south of Asia as far as the Philippine Islands and the Malay Peninsula. In Java a variety has developed (*P. malaccensis*). The White-throated Sparrow (*Zonotrichia albicollis*), an American form, is really a bunting. It has been found in the east of Scotland and the south of England. Other American sparrows have little in common with the genus Passer. The nostrils are in a small groove, and the tail is slightly forked.—The Hedge-sparrow (see WARBLER) is a bird belonging to an entirely different group; and the name sparrow is loosely given to various different birds in various parts of the world. For accounts of the destructiveness of the sparrow, see *The House Sparrow*, by J. H. Gurney, Russell, and Cones, and Miss Ormerod's Reports.

Sparrow-hawk (*Accipiter*), a genus of long-legged, short-winged falcons, nearly allied to and closely resembling the goshawks, but distinguished from them by their smaller size, weaker bill, and long, slender middle toe. The genus is represented in almost all parts of the world. The Common Sparrow-hawk (*A. nisus*), notwithstanding the constant war waged against it by gamekeepers, is still comparatively abundant in wooded districts throughout Great Britain and Ireland. It nests in trees, sometimes building a nest of its own, sometimes adopting one deserted by a crow or other bird. The eggs, four to six in number, are laid early in May, and are of a bluish-white colour marked with reddish brown. The food of the sparrow-hawk ordinarily consists of small birds, which it takes while on the wing, but when rearing its blood it often commits great havoc among young game-birds and poultry. The adult male measures 12 inches, and has the upper parts of the body bluish gray, the under parts buff-coloured, with bright rufous bars. The female is paler in colouring and measures about 15 inches. The sparrow-hawk was used in falconry, but its feebler powers of flight made it of less value than the true falcons. It is bold and active, however, and is still often trained to take partridges and small birds; and it is recorded that a single trained sparrow-hawk took 327 birds in less than two months. The American Sparrow-hawk (*Falco sparverius*) is similar in size to the European, but is more nearly allied to the kestrel.

Common Sparrow-hawk (*Accipiter nisus*).

Sparta, anciently LACEDÆMON, the capital of Laconia, and the most famous city of the Peloponnesus, situated on the right bank of the Eurotas, about 20 miles from the sea, in a plain shut in by mountains, of which that on the west side, Mount Taygetus, rises to a height of 8000 feet. The natural defences of the valley of Lacedæmon were so great that it continued unfortified down to the Macedonian period, and indeed was not regularly fortified till the time of the tyrant Nabis (195 B.C.). Previous to the Dorian conquest the primitive Achæans of Sparta seem to have dwelt in four or five scattered hamlets. These in course of time were grouped into one city by the conquerors, and became known as town-districts. Sparta had no striking public buildings—its Acropolis was merely a steep hill in the northern part of the city, crowned with the temple of Athena *Polinchos* or *Chalciœcus*. Here, as in all Dorian states, were found the three classes—*Helots*, or slaves; *Perioikoi*, a subject class of freemen without political rights; and the *Spartiatai*, or the governing class of pure Dorian blood. The foundation of Spartan greatness was attributed to the legislation of Lycurgus (q.v.), and it is at any rate true that there survived a very ancient legal code, consisting of *ῥῆτραι* ('compacts'), supposed to have the special sanction of the Delphic oracle. At the head of the government stood two *kings*, one of the family of the Agidæ, the other of the family of the Eurypontidæ, their royalty hereditary in the main line, but limited to sons born while the father was actually king. Their powers were equal, and they were originally priests as well as judges and generals. After 506 B.C. only one king at once might take the field, and his powers came to be much curtailed by the growing power of the Ephors. These were five in number, elected annually by the people—the first giving his name to the year. Two accompanied the king on campaign, advising the three at home by the *σκυτάλαι*, or secret despatches. They received foreign ambassadors, imposed taxes, and judged in all matters except those which specially belonged to the kings as priests. The standing council of kings and ephors was the *Gerousia*, consisting of twenty-eight Spartans above sixty, and elected from the chief families by the people. Once a month was held the *apella*, or assembly of all Spartans above thirty, who might vote but could not speak, which only the king, ephors, and members of the gerousia had the right to do. The Spartans never ceased to look upon themselves as merely a military garrison, and all their discipline pointed to war. No deformed child was allowed to be brought up; boys began to be drilled at seven, entered the ranks at twenty, and thereafter had to dine every day in one of the military messes (*ἀνδρεῖα* or *φιδίτια*) in tents pitched in the public street. From twenty till sixty all Spartans were obliged to serve as Hoplites. In the 5th century the army was divided into twelve *lochoi*, commanded by *lochagoi*. Each *lochos* consisted of 500 men. After the Peloponnesian war the army was rearranged in six *morai*, each under a *polemarchos*. They never were strong at sea, although at Salamis they had ten ships, and under Lysander defeated the Athenian fleet and so ended the Peloponnesian war.

The earliest struggles of Sparta were with Messenia and Argos. The Messenian war terminated (668 B.C.) in the complete overthrow of the Dorians of Messenia, who were reduced by the victorious Spartans to the condition of Periœci. Similar struggles occurred both with the older Achæan inhabitants in the centre of Peloponnesus and with the Dorians of Argos, &c., in which the Spartans were generally successful. Under their stern discipline the Spartans became a race of resolute, rude, and narrow-minded warriors, capable of a momentary self-sacrificing patriotism, as in the story of the 300 heroes who fell at Thermopylæ, but utterly destitute of the capacity for adopting or appreciating a permanently noble and wise policy. The outbreak of the Peloponnesian war (431 B.C.) brought the rivalry between Sparta and Athens to a head, and in the mighty struggle that ensued victory declared on the side of the combatant least capable of maintaining the greatness of Greece. Sparta now attained the hegemony of Greece; but her insolent tyranny in the hour of her triumph excited the indignation of those whom she held in virtual subjugation, and the glorious retaliations of the Thebans under Epaminondas stripped her of all her splendid acquisitions, and reduced the Laconian state to its primitive boundaries. Later the rise of the Macedonian power limited still more the Spartan territory, nor did it ever after attain its earlier dimensions. After a series of vicissitudes Sparta passed into the hands of the Romans, became a portion of the Roman province of Achaia, and finally shared the fortunes of the rest of Greece (q.v.). The growth of the town of Misthra, 2 miles SW. of Sparta, in the 14th and 15th centuries, led to the total desertion of the more ancient city; but the modern town of *Sparti* (pop. 5000), which was founded by the Greek government in 1836, occupies part of the site of old Sparta, and is again capital of the province of Laconia.

Spartacus, leader of the Roman slaves in the great revolt which broke out about 73 B.C., was a Thracian by birth, and from a shepherd had become a leader of a band of robbers when he was captured and sold to a trainer of gladiators at Capua. He formed a conspiracy to escape, and, when it was discovered, broke out with some seventy followers, with whom he made for the crater of Vesuvius, where hordes of runaway slaves soon joined him. He first overpowered and seized the arms of a force sent against him from Capua, next routed an army of 3000 men under C. Clodius, and so passed from victory to victory, overrunning Southern Italy and sacking many of the cities of Campania, his numbers growing to forty, seventy, and even a hundred, thousand men. Great part of Central and Southern Italy had been thrown into pasture-land, on which the flocks belonging to rich absentee nobles were tended by gangs of discontented slaves, who flocked eagerly to the standard of revolt. Spartacus, who failed to get support from the Italian communities, and from the first knew the real weakness of his position, strove to persuade his victorious bands to march northwards to the Alps and disperse to their native regions; but they were intoxicated with victory, and saw glittering before their eyes all the plunder of Italy. Against his better judgment he continued the war, showing himself a consummate captain in the strategy and valour with which he routed one Roman consular army after another, and the policy by which for long he assuaged the jealousies and dissensions amongst his followers. At length in 71 M. Licinius Crassus received the command, and after some time of cautious delay forced Spartacus into the narrow peninsula of Rhegium, from which, however, he burst out through the Roman lines with a portion of his force. Crassus, in despair, urged the senate to recall Lucullus from Asia and Pompey from Spain, but meantime he himself pursued active hostilities against the dreaded enemy. Spartacus finding all hope at an end made a dash on Brundusium, hoping to seize the shipping and get across the Adriatic, but was foiled by the presence of Lucullus, whereupon he fell back upon the river Silarus, and there made a heroic stand against Crassus until he was cut down.

Spartanburg, capital of Spartanburg county, South Carolina, 93 miles by rail NNW. of Columbia. Bricks and carriages are manufactured; and here are boys' and girls' high schools and the Wofford (Methodist; 1853) College. Pop. (1890) 5544.

Spasm (Gr. *spasma*) consists in an irregular and violent contraction of muscular parts—involuntary even when the voluntary muscles are concerned. There are two sorts of spasm. In one there is an unusually prolonged and strong muscular contraction, not rapidly alternating as usual with relaxation, the relaxation only taking place slowly, and after some time. This is known as *tonic spasm* (Gr. *tonos*, 'a bracing up') or *Cramp* (q.v.). When in a more moderate degree affecting the voluntary muscles generally it constitutes Catalepsy (q.v.), in which, from the muscles remaining contracted, the limbs will retain whatsoever attitude they are placed in, until the spasm is over. But the extreme example is Tetanus (q.v.), in which the spasms are so violent and so enduring that they may be said to squeeze the patient to death. In the other form of spasm the contractions of the affected muscles take place repeatedly, forcibly, and in quick succession; the relaxations being, of course, equally sudden and frequent. This is named *clonic spasm* (Gr. *klonos*, 'an agitation'), and is popularly known as *convulsions*. The spasmodic twitchings which sometimes occur in the muscles that close the eyelids (orbicularis palpebrarum) are familiar to almost everybody, and are an example of clonic spasm on a very small scale. Epilepsy and convulsive hysteria afford the best examples of this kind of spasm. Chorea (q.v.), or *St Vitus's dance*, is an allied but less regular and characteristic form.

The treatment varies according to the cause of the excessive muscular irritability. Firm pressure on muscles affected with spasm will promote their relaxation, and by strong steady pressure on the masseter muscles the lower jaw has been depressed, so as to open the mouth, in cases of lock-jaw. The medicines which are employed to counteract irregular or inordinate muscular action are termed *antispasmodics;* but spasm may depend upon so many different causes that the remedies which are found most successful in combating it must vary extremely in their nature. There are, however, a few medicines which appear to exercise a control over spasmodic action generally. These may be termed *pure* or *true* antispasmodics. They are Asafœtida, Cotyledon umbilicus (or Common Navel-wort), Wood-soot, Galbanum, Musk, Rue, Sagapenum, Sumbul (Jatamansi or Musk Root), and Valerian and the Bromides. Amongst the narcotics often useful in these affections we may especially mention Belladonna, Cannabis Indica (or Indian hemp), Chloral, Opium, and Stramonium. Sulphuric ether in draught or inhaled, and inhaled chloroform, are often of service. In some cases, remedies which directly depress the vital powers, such as the prolonged use of the warm bath, or even, in rare cases, the abstraction of blood, are the most effectual means of subduing spasm.

Spasmodic School, a name applied to a group of English poets about the middle of the 19th century, among whom were Philip James Bailey, Sydney Dobell, and Alexander Smith. The name implied an overstrained and unnatural method of sentiment and expression, which sometimes grew out of sheer affectation and not seldom sank hopelessly into bathos. Professor Aytoun's *Firmilian* (1854) was an excellent burlesque of the high-strung and grandiose style of these poets who took themselves much too seriously, and were for a moment also taken at their own valuation by the world.

Spathe (*Spatha*), in Botany, a sheathing bract which encloses one or more flowers, as in the Narcissus. Very frequently the flowers within a spathe are arranged upon a *spadix*, which is a succulent spike, with numerous flowers, and of which a familiar example may be seen in *Arum maculatum*. The spadix is a characteristic feature of the Palms, and in them is compound or branching, and in general is provided not only with a common spathe, but with secondary spathes at its divisions.

Spathic Iron Ore. See Iron, Vol. VI. p. 216.

Spavin, a disease of horses, occurs under two different forms, both interfering with soundness. In young, weakly, or overworked subjects the hock-joint is sometimes distended with dark-coloured thickened synovia or joint-oil. This is bog spavin. Fomentations, occasional friction, a laxative diet, and rest should be diligently tried; and if such remedies prove unsuccessful the swelling must be dressed with strong blistering ointment or fired. The second variety of spavin is the more common. Towards the inside of the hock, at the head of the shank-bone, or between some of the small bones of the hock, a bony enlargement may be seen and felt. This is bone spavin. At first there is tenderness, heat, swelling, and considerable lameness; but as the inflammation in the bone and its investing membrane abates the lameness may entirely disappear, or a slight stiffness may remain. In recent and slight cases cold water should be applied continuously; but in serious cases, when the part is swollen and tender, hot fomentations are best. For several days they must be perseveringly employed. When the part is again cool and free from pain an iodide of mercury or fly-blister should be applied, and the animal treated to three months' rest in a small paddock, the end of a barn, or a roomy loose box. In persistent cases firing or setoning usually gives much relief.

Speaker. See PARLIAMENT, Vol. VII. p. 774.

Speaking-trumpet, an instrument for enabling the sound of the human voice to be conveyed to a greater distance. It is of the utmost use on shipboard in enabling the officers to convey orders during windy weather from one part of the deck to another, or to the rigging. The invention is ascribed to Sir Samuel Morland, in 1670, though Athanasius Kircher laid claim to it. Morland's trumpet was of the same form as that now in use—viz. a truncated cone, with an outward curve or lip at the opening. The theory of the action of this instrument is much the same as that of the sounding-board of a musical instrument, but the sounding-board is aerial instead of solid. The air immediately in front of the instrument is acted upon over so wide a surface that it cannot effectively evade compression and rarefaction by any process of overflow and inflow towards the sides, and the result is as if the air were well laid hold of and firmly set in vibration.

Spear, a weapon of offence, consisting of a wooden shaft or pole varying in length up to 8 or 9 feet, and provided with a sharp piercing point. The spear may be regarded as the prototype of the various forms of piercing weapons, such as the arrow, bolt, and dart, which are projected from bows, catapults, or other engines, and the javelin, assegai, and lance, held in or thrown by the hand. The longer and heavier spears and lances are mainly retained in the hand while in use, but there is no absolute distinction, and the throwing of a spear has in all ages been a form of offensive warfare. There can be no doubt that a weapon such as the spear is the most ancient, as well as the most universal, of warlike and hunting weapons. In its earliest form the spear would naturally consist of a simple pole of tough wood sharpened to a point at one extremity, which point might be both formed and hardened by charring in fire. From this an improvement would consist in fitting to the shaft a separate spear-head of bone, as is still practised amongst primitive races. No trace of these early spears remains to us, but of the more developed forms having heads of chipped flint or other hard stones examples are plentiful, and most ingenious methods of fixing such heads are yet practised by South Sea tribes, who carve, paint, and otherwise ornament their spears in an elaborate manner. To flint-heads succeeded heads of bronze (see Vol. II. p. 478), but these came only late in the bronze period, and were still in use when the Homeric poems were composed. The bronze spear-heads found in Great Britain and in northern Europe generally were cast with sockets, into which the end of the shaft was inserted, but on the eastern Mediterranean coasts tanged spear-heads were used. These spear-heads were various in form and size, some being three-edged like the old bayonet, others with expanded leaf-shaped blades, some barbed, and some having loopholes either in socket or blade by which they were lashed to the shaft. The war-lance of the mediæval knights was 16 feet long; the weapon of modern cavalry regiments known as lancers may be from 8½ to 11 feet long, usually adorned with a small flag near the head. The Persians at the present day forge spear-heads, for ornamental purposes only, with two and sometimes three prongs. The modern spears of savage tribes, used equally for hunting and for warlike purposes, are frequently barbed with fish and other bones, and their fighting-spears have sometimes poisoned tips. Among the South Sea Islanders a fishing-spear having several slender barbed points is an important weapon. Among civilised communities the hunting-spear continues to be used for following the wild boar and other large game. See also PIKE, HALBERT, TRIDENT.

Species. This is a term which it is very difficult to define with precision. The word itself means a look, an appearance, a kind; and in common usage things that look the same are said to be of the same species. With more definiteness naturalists speak of a mineral species, and of a species of plants or animals. *It is with this last usage that we are here concerned.*

In classifying plants or animals we form conceptions of various degrees of comprehensiveness (see BIOLOGY), and for these we use a series of terms, such as class, order, family, genus, species, variety. The need for precision is that every one may know exactly what is meant when any individual or group of individuals is named. In the ordinary system of classification a species is a group of individuals which closely resemble one another, and the species is usually subordinated to a genus—a wider group of similar, but less closely similar, forms—and is superior to a variety, of which there may be several in a species. Thus we group the lions as a species (*Felis leo*) of the genus Felis, in the family Felidæ, order Carnivora, class Mammalia, and call the tigers, leopards, cats, and the like other species of the same genus Felis. As no one could confuse lion, tiger, and leopard, for the peculiarities of each are well marked, it may be wondered what difficulty there is in defining species.

Let us consider the matter practically. We observe our fellow-men; we see that they differ in many ways from one another, in stature, in features, in complexion, in colour of eyes and hair, and so on; but we do not think of speaking of a red-haired or a blue-eyed species of man. We should as soon think of saying that the red-haired or blue-eyed child in a family was of a different species from its brothers and sisters or from its parents, which would be absurd. We at once agree with the systematist when he says that the term species should not be given to a group of individuals which are distinguished from other groups by no greater differences than distinguish members of a family, and when he says that the characters of a species must have some constancy from generation to generation, which is not of course the case with red hair or blue eyes. This is a common-sense way of limiting the term, but it leaves many difficulties untouched. It is not readily applied to extinct species, of whose generations and individual variations we cannot know much; nor has it been applied to a vast number of forms recorded as species sometimes on the strength of single specimens, and often without any knowledge of their generations.

But, again, we observe men with much greater peculiarities than red hair or blue eyes; we contrast Britons and Chinamen, Lapps and Negroes, and we wonder if these really belong to the same species. Here, however, the systematist reminds us that the members of a species are fertile *inter se*, which cannot be denied of the different races of mankind. But a little knowledge is enough to keep us from attaching very much weight to this distinction, since both among plants and animals there are many cases of fertile hybrids between different species. We can no longer talk as if the mule were the only known hybrid. See HYBRID.

Or if we turn to the systematic treatises which classify plants and animals, and compare half a dozen of them, we find ample evidence of the elasticity of the conception of species. *Quot homines tot sententiæ.* Thus, as Haeckel notices, one botanist enumerates 300 German species of the common Composite, Hieracium; another reduces them to 106, another to 52, another to about a score! Bechstein said that there were 367 species of birds in Germany, but according to Reichenbach there are 379, according to Meyer and Wolf 406, according to Pastor Brehm 900! But Haeckel himself supplies the best example, for in his important monograph on Calcareous Sponges he admits that as the naturalist likes to look at the problem there are 3 species, or 21, or 289, or 591! We are told that species are groups of individuals agreeing in essential characters which remain constant from generation to generation. But what are essential characters? and how much constancy is demonstrable?

We cannot forget, for instance, how one species may include forms so very different as Shetland pony, hunter, and dray horse; or as poodle, bulldog, and greyhound; or as carrier, pouter, and fantail; or as cabbage, cauliflower, and Brussels sprouts. Yet it is probable that in each of these four groups the diverse forms have been derived from the same ancestral wild species, and in each case the diverse forms are connected by intermediate stages.

In short, the fact is that there is no such thing as species. Individuals are real; but a species is a subjective conception. It is based on structural resemblances between individuals, and the degree of importance attached to these depends, as we have seen, on the mind of the observer, or is, in other words, entirely relative.

But while there can be no perfectly strict definition of a species in terms of morphology, it may be asked, where is there a possible one in terms of physiology, in terms of functional peculiarities about which there can be no dispute? At one time it almost seemed that there might be some solution in terms of fertility and infertility. But, although this distinction is certainly helpful and very important, it also breaks down. It is not of course doubtful that species have physiological peculiarities; lions differ from tigers in habit and chemical composition as well as in form and structure; but every individual has also its peculiarities—chemical as well as personal; the difficulty is to decide when these peculiarities are important enough to make it useful to give a precise name to their possessors.

As to the practical question of determining species it should be borne in mind that the differences between one form and another are often very marked, and that the gap between related forms is not always bridged by any unbroken series. The New Zealand lizards (*Hatteria punctata*) not only form a species, but are the sole living representatives of an order, or of a class; and the same may be said of the lancelet and other forms. It is with those organisms of which there are very many more or less different forms that there is real difficulty—with Bacteria, Algæ, Protozoa, Sponges, Crustaceans, Insects, Fishes, Birds, and so on. In such cases the naturalist who admits that species is but a relative conception, and who, as an evolutionist, recognises the variability of species and the links of relationship which bind form to form, cannot do more than try to make sure that the peculiarities on account of which he gives a new name to any group of creatures are greater than those which distinguish the members of a family of these, are relatively constant from generation to generation, and are associated with reproductive variations which tend to restrict the range of mutual fertility to the members of the proposed new species. Unfortunately, however, species often are and sometimes must be established for single specimens, without any knowledge of their reproduction and generations, without any statistics of their variations, or careful comparison of these with those of related forms. Where the form in question is conspicuously unique the erection of a new species is of course readily justified.

History.—The history of the biological conception of species can be rapidly sketched. We need not go farther back than John Ray (1628–1705), who gave to the term species that meaning which it bore until evolutionary conceptions prevailed. Linnæus adopted the usage defined by Ray, and by introducing the 'binomial nomenclature' made it more serviceable. He believed in real species, and said: 'Species tot sunt diversæ, quot diversas formas ab initio creavit infinitum ens,' though some hesitancy in regard to this is shown when he elsewhere expresses the idea that all the species of a genus *ab initio unam constituerunt speciem.* Although Lamarck in 1809 declared species to be artificial conceptions, the Linnean idea prevailed—even in Agassiz' *Essay on Classification* (1859)—until Darwin and his fellow-workers modified this among many other conceptions by establishing the doctrine of evolution, 'by which,' as Ray Lankester says, 'universal opinion has been brought to the position that species, as well as genera, orders, and classes, are the subjective expressions of a vast ramifying pedigree in which the only objective existences are individuals.'

See BIOLOGY, BOTANY, DARWINIAN THEORY, EVOLUTION, GENUS, VARIATION, ZOOLOGY. See also Darwin, *Origin of Species* (1859); Haeckel, *Generelle Morphologie* (1866); *Naturliche Schopfungsgeschichte* (1868; 8th ed. 1889; trans. *Natural History of Creation*, Lond. 1870); *Die Kalkschwamme* (1872); Spencer, *Principles of Biology* (1864–66); Wallace, *Darwinism* (1889).—The species of Logic is originally suggested by Natural Species, and may be defined as a group of individuals agreeing in some common character and known by a common name; two or more species constituting a genus. The relation of species to the other logical elements of classification are treated at PREDICABLES and GENERALISATION. The great controversies as to the real existence of species and other universals are sketched at NOMINALISM.

Specific Density, the mass of any given substance contained in unit volume. On the centimetre-gramme-second system of physical units, since a cubic centimetre of water at standard temperature and pressure weighs 1 gramme, the density of water = 1, and water is the standard of density; and the specific density of a body is the number of grammes' mass per cubic centimetre. Since, according to the law of gravity, weights are proportional to masses, it is convenient to ascertain specific densities by ascertaining the specific gravities of the substances tested. For example, an English gallon of water weighs at standard temperature and pressure (62° F. and barometer 30 inches) 10 lb. avoirdupois; a gallon of ether weighs 7·2 lb.; the specific density of ether is therefore 7·2 ÷ 10 = 0·72. Similarly, a gallon of strong sulphuric acid weighs 18·4 lb., and the specific density of sulphuric acid is 1·84. The specific densities of solids may be determined by the hydrostatic balance (see ARCHIMEDES, PRINCIPLE OF), which gives the weight of a quantity of water equal to that of the solid; or by using a 'specific gravity flask.' This is a flask marked distinctively at a certain level; the solid is put into this; the flask is filled with water up to the mark, and weighed; the whole is then emptied and filled with water alone up to the mark, and again weighed. The two weighings give the data for ascertaining the ratio between the weight of the solid and that of an equal bulk of water. If the solid is acted upon by water, some other liquid of known specific density must be employed, and the calculation varied accordingly. If it be lighter than water, it is coupled with a piece of heavy substance whose weight and specific density are separately known, and the aggregate apparent loss of weight incurred by the combination on being immersed in liquid is found by the hydrostatic balance. Of this aggregate so much is due to the heavy substance and the remainder to the light solid. This gives data for calculating the specific density of the light solid. The specific density of a liquid is ascertained by simply comparing the weights of quantities of that liquid and of water successively made to fill the specific gravity flask up to the same marked level; or by comparing the apparent losses of weight incurred by a solid on being immersed in water and in the liquid respectively; or by the use of hydrometers or areometers. The areometer (*araios*, 'thin,' and *metreō*, 'I measure;' Fr. *aréomètre* or *pese-liqueur*; Ger. *Araometer* or *Senkwage*) or hydrometer is a graduated instrument which floats in a liquid, without being wholly submerged, under the equilibrium of the weight of the whole body acting downwards, and the buoyancy of the liquid, equal to the weight of the part of the liquid displaced, and acting upwards. The specific density of a uniform cylinder, say of ice, floating vertically in water is the volume immersed ÷ the whole volume; and in liquids of different specific densities such cylinders would sink to different depths. But it is more convenient to use graduated hollow glass instruments weighted with mercury at one end to make them float vertically (see fig. 1). AB is graduated; C is a large bulb; D is a small bulb containing mercury, the quantity of which is so adjusted that the instrument sinks in water, say to the point W. If the liquid be heavier than water the instrument will not sink so far; the position of equilibrium in which the weight of the whole instrument is equal to the weight of the liquid displaced will be sooner reached; and, conversely, if the liquid be lighter than water the instrument will sink farther. Each instrument must be experimentally graduated by placing it in liquids of known specific densities. By varying the adjustment of the mercury a series of instruments may be made, serviceable in ascertaining the specific densities of liquids within particular ranges of density—e.g. instruments for sulphuric acid, milk, alcohol, &c. The delicacy of such an instrument depends on the bulb C being large and the stem AB thin. The chief modes of graduation are (1) Gay-Lussac's areometer or volumometer. In water the instrument stands at 100°. All the degrees are equal, and each = $\frac{1}{100}$ the volume of that part of the instrument which is immersed when it floats in water. If n be the numerical reading when the instrument is floated in a given liquid, the specific density of that liquid is $100 \div n$—e.g. if the instrument stand at 80°, the specific density = 100/80 = 1·25. (2) Baumé, for liquids heavier than water. Water at 17·5° C. = 0°; an aqueous solution containing 10 per cent. by weight of common salt (NaCl) at 17·5° C. = 10°; the scale is uniformly graduated; specific density = $146{\cdot}8 \div (146{\cdot}8 - n)$. (3) Baumé, for liquids lighter than water; 10 per cent. by weight salt-solution at 12·5° C. = 0°; water at 12·5° C. = 10°; specific density = $146 \div (136 + n)$. (4) 'Rational' Baume, for liquids heavier than water; water at 15° C. = 0°; sulphuric acid, specific density = 1·842 = 66°; specific density = $144{\cdot}3 \div (144{\cdot}3 - n)$. (5) Cartier, resembles Baumé; for liquids lighter than water, 21° Cartier = 21° Baume; otherwise 15 Cartier degrees = 16 Baume degrees: specific density = $136{\cdot}8 \div (126{\cdot}1 \mp n)$. (6) Beck; pure water = 0°; specific density, 0·850 = − 30°: uniform graduation; specific density = $170 \div (170 \mp n)$. (7) Twaddell, most used in England; water = 0°; graduation not uniform, but readings direct; specific density = $(1000 + 5n) \div 1000$—e.g. a gallon of acid of 24° Twaddell weighs 10 lb. × $\frac{1000 + 120}{1000}$ = 10 lb. × 1·12 = 11·2 lb. (8) Tralles, an alcoholometer scale used on the Continent, adjusted so as to show directly the volume-percentage of alcohol in alcohol and water. (9) Sikes, used in the British Customs and Excise; graduated so as to show how many volumes of water must be added to or taken from 100 volumes of the mixture under examination to reduce it to proof-spirit (a mixture whose density = $\frac{12}{13}$ that of water at 51° F.—i.e. 57·09° Tralles), the instrument being adjustable to different ranges of density by a set of movable weights. Instead of making the quantity of liquid displaced to vary, as in the above instruments, the displacement may be kept constant and the weight of the instrument varied. Fig. 2 shows Nicholson's areometer—a hollow brass case, BC; cups at A and D; a weight at E. Suppose it weighs 2000 grains; and let it sink in water to a certain mark between B and A when 500 grains weight is put in A. If it be now transferred to another liquid in which only 250 grains are required to make it sink to the same mark, the second liquid is lighter than water in the ratio of 2250, the whole weight of the apparatus, to 2500, its former whole weight; and its specific density is therefore $\frac{2250}{2500}$ = 0·9. The same instrument may be used to find the specific density of small solids thus: put a little stone or gem in A; to make the apparatus sink to the mark say 440 grains are required; therefore the stone weighs 60 grains. Now put it in D. More weights, say 20 grains, must now be put in A; the 20 grains represent the apparent loss of weight in water; the specific density = weight in air ÷ apparent loss in water = 60/20 = 3. By reversing D, which is perforated, the specific density of bodies lighter than water may be ascertained. Fahrenheit's areometer, the original form, differs from Nicholson's in having no platform or cup D. Rousseau's densimeter combines the two methods described above. It bears a cup or cavity at its summit. This is filled successively with various liquids; each induces a different amount of sinking. The instrument-maker has to do the preliminary graduation by the use of known liquids. Specific-gravity bulbs are also used; they are marked with numbers representing specific densities. Those which are too heavy sink; those which are too light float; the one exactly corresponding to the density of the liquid, if there be one, neither rises nor sinks. The most accurate method is that by the specific gravity flask. The specific density of a gas or vapour is determined (1) by weighing a copper flask when empty, when filled with the gas, and when filled with air, which method gives the density of the gas relatively to that of air, when proper corrections are made so as to compare the two gases at the same temperature and pressure; (2) by ascertaining the volume occupied by a given weight of the gas or vapour at a

Fig. 1.

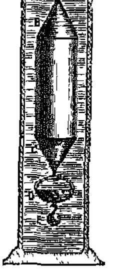

Fig. 2.

known temperature and pressure; (3) by measuring the weight of vapour which can occupy a known volume, this being effected by putting liquid into a vessel of known capacity and heating until there is, at a known temperature and the atmospheric pressure, nothing but vapour in the vessel, then closing and weighing when cool. The last two methods are specially applicable to vapours rather than to permanent gases. It is often convenient, instead of taking the true specific density of a gas or vapour -e.g. that of air, the number of grammes per cubic centimetre of which is 0·0012932—to state its density as compared with air or hydrogen as a standard. In this way air is said to have a density = 1 or = 14·47, according as air or hydrogen is taken as the standard. The use of hydrogen as a standard is of special convenience in chemical calculations, for the densities of gases or vapours so measured are, as a rule, proportional to their *molecular weights. The following are the specific* densities of some common substances:

Air	0·0012932
Alcohol	0·80
Aluminium	2·56 to 2·67
Amber	1·08
Ammonia gas (= 0·589 × air)	0·000762
Ammonia solution	0·88
Amorphous arsenic	4·71
Anthracite	1·4 to 1·7
Antimony	6·715
Arsenic crystals	5·73
Ash	0·84
Bismuth	9·9
Blood	1·04
Bone	1·6 to 2·0
Brown coal	1·2 to 1·4
Butter	0·94
Calcium	1·578
Cannel coal	1·16 to 1·27
Carbonic acid gas (= 1·524 × air)	0·00197
Cast-iron	7 to 7·6
Chalk	2·45
Charcoal	0·3 to 0·5
Chlorine (2·4502 × air)	0·00317
Clay	1·8 to 2·6
Cobalt	8·95
Copper	8·85 to 8·94
Cork	0·24
Cyanogen (1·806 × air)	0·00234
Diamond	3·53 to 3·55
Dry peat	0·5
Elm	0·67
Flint	2·6 to 2·7
Glass	2·4 to 3·5
Gold	19·26 to 19·55
Granite	2·5 to 2·9
Honey	1·45
Human body alive	0·89
Hydriodic acid (= 4·44 times that of air or 64·11 times that of hydrogen)	0·00574
Hydrochloric acid gas (= 1·26 × air)	0·00163
Hydrochloric acid solution at 32° F.	0·908
Hydrocyanic acid gas (= 0·9476 × air)	0·1225
Hydrogen (= 0·06926 × air)	0·00008958
Ice	0·91674
Iridium	22·42
Ivory	1·8 to 1·9
Lead	11·37
Lignum-vitae	1·33
Limestone	2·6 to 2·8
Liquefied oxygen	1·124
Lithium	0·5936
Loadstone	4·9 to 5·2
Manganese	7·2
Marble	2·5 to 2·8
Mercury	13·59
Milk	1·03
Nitric acid	1·517
Nitrogen (0·9713 × air)	0·00126
Oak, English	0·97
Oil of cloves	1·03
Oil of turpentine	0·87
Olefiant gas (= 1 9784 × air)	0 01265
Oxygen (= 1·1056 × air)	0·00148
Platinum	21·1 to 21·7
Poplar	0·38
Potassium	0·86
Ruby	4·3
Sand in bulk, dry, about	1·5
" " wet	1·9 to 2·0
Silver	10·53
Sodium	0·972
Spanish mahogany	1·06
Steel	7·6 to 7·8
Sulphuric acid	1·854
Sulphuric ether	0·72
Sulphurous acid gas (= 2·24 × air)	0·0029
Tin	7·29
Topaz	3·4 to 3·6
Wrought-iron	7·25 to 7·79
Zinc	6·86 to 7·21

Specific Gravity, the *weight* of any given substance as compared with the weight of an *equal bulk* or volume of water or other standard substance at the same temperature and pressure. See Specific Density.

Spectacles, for the purpose of aiding the sight when impaired by age or otherwise (see Eye), are commonly said to have been invented during the 13th century. The merit is variously attributed to Alessandro di Spina, a monk who died at Pisa in 1313, and to Salvino degli Amati, who died at Florence in 1317; but spectacles seem to be referred to by the Arab writer Alhazen (11th century) and by Roger Bacon (c. 1214–94). In 1482 there were spectacle-makers at Nuremberg. At first spectacles were exceedingly clumsy, both in the lenses themselves and also in their frames; and very little improvement took place in them until the beginning of the 19th century, when light metal frames were introduced instead of the cumbrous horn or tortoiseshell mountings, which are still occasionally seen, and have obtained the name of goggles. So skilful are the workmen of Wolverhampton, where they are chiefly made, in the manufacture of steel frames that some of exquisite workmanship are now turned out, which, with their lenses complete, are under a quarter of an ounce in weight. They have consequently displaced gold, silver, and all other materials, when comfort and effectiveness are desired. The lenses themselves are nearly always made of the best optical glass, and by the best makers are ground with extreme care. Many profess to be made of 'pebbles' or rock-crystal; but lenses really made of that material are exceedingly rare and have no real advantage over good glass. The spectacle-frame ought to be so fitted that the optic axes of the lenses shall coincide with those of the eyes; otherwise there is a strain on the eyes.

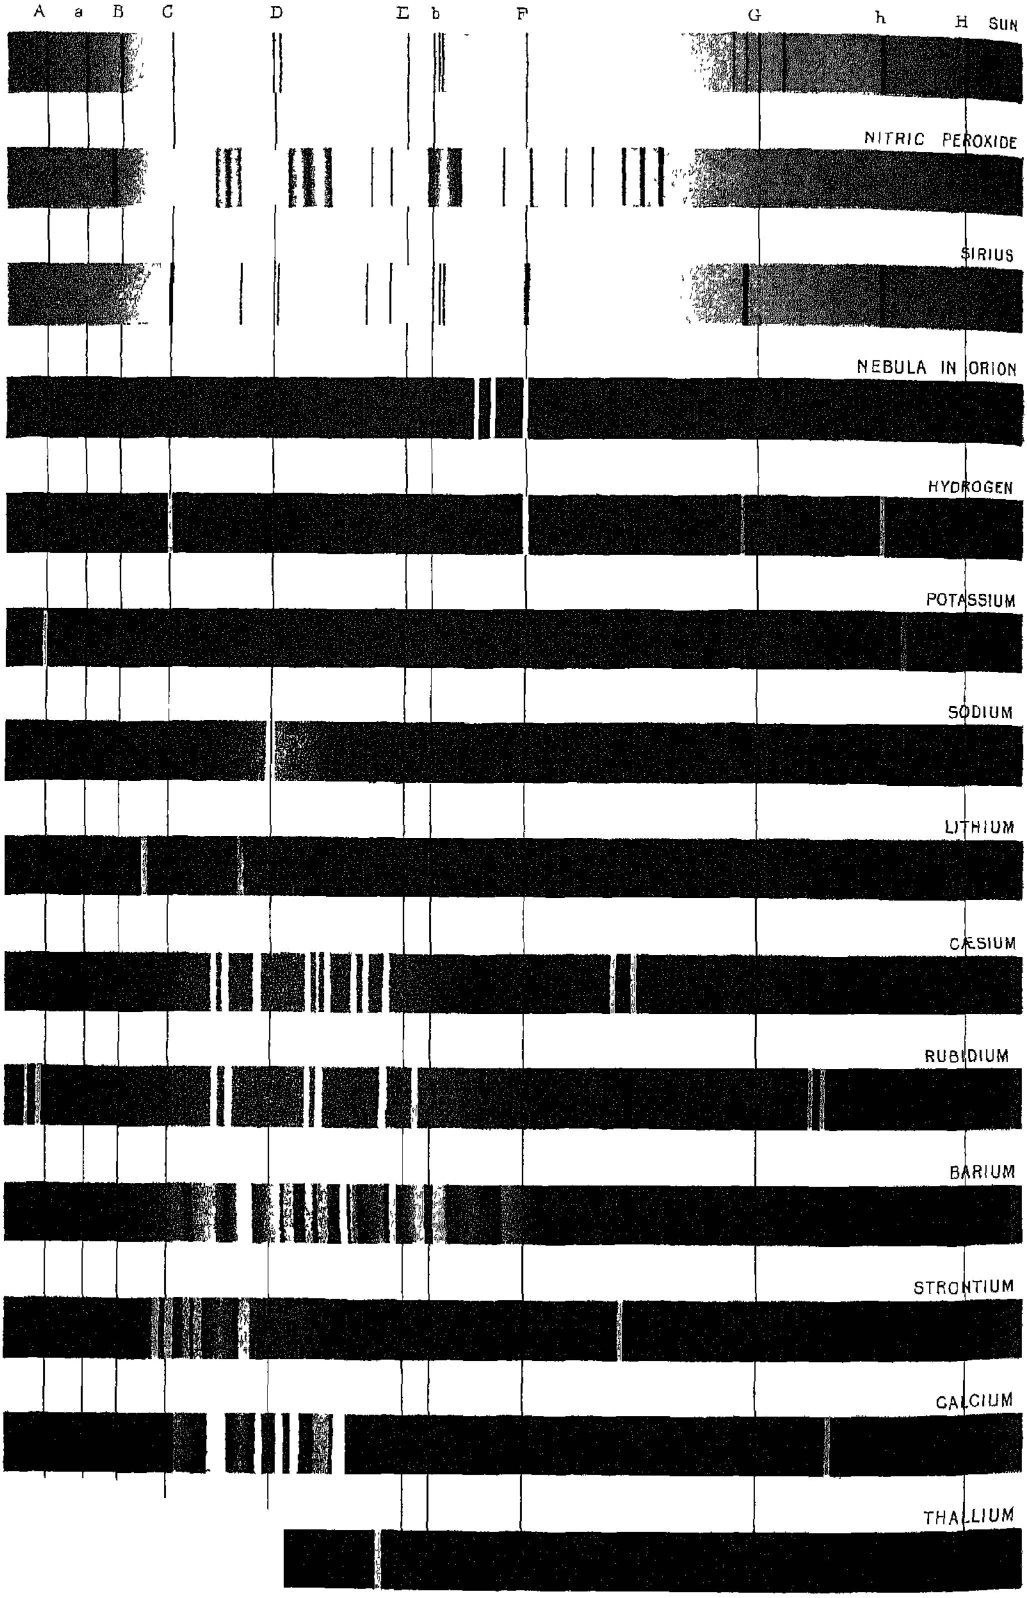
It is most important that the glasses worn should *be properly selected, otherwise they may do* much harm. In cases of Astigmatism (q.v.), and those where the two eyes are different, competent medical advice should always be sought. In simple myopia (short-sight) and hypermetropia (long-sight; see Eye, Vol. IV. p. 515) the general principles of selection are less complex, though their proper application is often a difficult matter. In short-sight the glasses (concave) used should be the *weakest* with which distant objects are clearly seen, or somewhat weaker; in long-sight the glasses (convex) should be the *strongest* with which distant objects are clearly seen; for reading and near work still stronger glasses are often required. In presbyopia or old-sight (Vol. IV. p. 512) the glasses should be of such a strength as to enable print to be comfortably read at about 10 inches from the eyes.

Spectrum. As explained under the article Colour, light emanating from any ordinary source is rarely if ever homogeneous. It is composed of rays of different wave-lengths, each of which if viewed singly would appear to have an appropriate colour. The general colour-sensation produced by such a heterogeneous ray can teach us very little concerning its composition. Not until we have formed its spectrum by appropriate means are we able to analyse it. A spectrum is in fact an image in which the component parts of a given ray of light are separated from one another so that each may be viewed singly.

Newton was the first who scientifically produced and studied the spectrum of sunlight. This he did by interposing a glass prism in the path of a ray which was allowed to enter a dark room through a small hole in the shutter. The arrangement is shown diagrammatically in fig. 1. Here the rays are bent out of their original course, SA, as they pass through the prism P; and on the screen, H, the spectrum of colours is formed instead of the image A. Newton regarded the spectrum as being divisible into seven differently coloured spaces, which he called in order red, orange, yellow, green, blue, indigo, and violet. It is impossible, however, to settle precisely the exact boundary between any two of these fancied species of colour, which pass by insensible gradations one into another. As *Newton clearly demonstrated, the spectrum* is produced because the differently coloured constituents of sunlight have different refrangibilities, the red being refracted least of all and the violet greatest of all (see Refraction). If light of a particular refrangibility were absent or of less intensity than the other constituents gaps would appear in the spectrum. As a matter of fact such gaps do exist in the solar spectrum, and were first observed by Wollaston in 1802. In 1817 Fraunhofer, with much more perfect optical apparatus, measured the relative positions of a great number of these *dark*

TABLE OF SPECTRA

Showing the Character of the light obtained from various sources



lines, and named the more important of them by the early letters of the alphabet. These are shown in the first spectrum in the table of spectra. They are the standard lines with which it is usual to compare the line characteristics of other spectra.

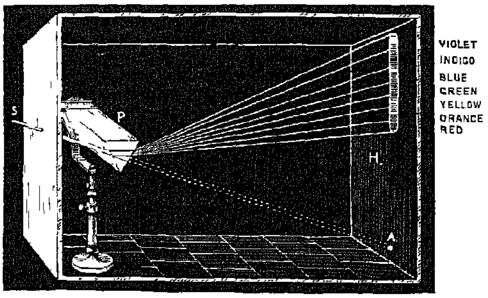


Fig. 1.

For the careful observation of these lines the spectroscope or spectrometer has been constructed. It consists essentially of a prism or train of prisms, P; a collimator, C, at the focus of whose lens, L, is placed a narrow slit, S, parallel to the edge of the prism; and a telescope, T, for producing a magnified image of the spectrum of the illuminated slit. Nearly all transparent refractory substances give similar spectra, although the dark lines may be somewhat differently spaced in the different cases. This arises from the fact that substances vary in their dispersive as well as in their refractive powers (see DISPERSION). The optical value of the spectroscope is that it gives us the means of accurately determining the refractive indices of different substances for rays of definite wave-lengths. Now, although refrangibility depends on wave-length, being in general greater for the shorter wave, it does not depend upon it according to any simple or common law. Hence in prismatic spectra the characteristic lines are not spaced in accordance with any simple relation to the wave-lengths of the corresponding rays. If, however, we substitute for the prismatic part of the spectroscope a diffraction-grating, we obtain a spectrum in which the rays are spaced according to a law of extreme simplicity.

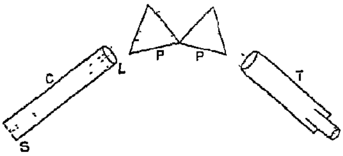

Fig. 2.

A diffraction-grating is formed by ruling a series of *fine lines* on a glass or metal surface. For the production of a good spectrum it is necessary that the lines should be equidistant and so close that several thousands go to an inch. If the image of an illuminated slit be viewed by a telescope through or after reflection from such a grating, a remarkable appearance is presented. A central luminous line is seen, just as if no grating existed, and for some distance on either side the field is dark. But soon on both sides spectra appear, with their blue ends nearest the central line. Still farther to left and right secondary spectra appear, their blue ends overlapping the red ends of the primary spectra. These are followed by a third but fainter set, and so on. These successive spectra are due to the Interference (q.v.) of the rays emanating from the discontinuous wave-front which has been made so discontinuous at the grating. The absolute position and breadth of the spectra depend on the closeness of the lines of the grating; but the relative positions of the coloured rays in any spectrum depend only on the wave-lengths. Thus in the solar spectrum produced by a diffraction-grating Fraunhofer's lines are so distributed that their distances from the central luminous line above mentioned are proportional to the wave-lengths of the corresponding rays of light. This spectrum is accordingly called the Normal Spectrum. Compared with it, the ordinary prismatic spectrum is much crushed towards the red end and extended towards the violet end. A rough comparison is shown in fig. 3, the principal Fraunhofer lines being given in the two spectra, which are of the same total length.

Professor Rowland, by means of his concave gratings, or gratings marked on a concave cylindrical surface of speculum metal, has produced remarkably fine spectra. Because of the slight concavity the grating focusses the spectrum clearly at a particular distance, so that the object-glass of the telescope may be dispensed with.

We have now to consider the significance of the dark lines in the solar spectrum. These gaps may be imagined as originating in two ways. They may be absent in the sunlight from the very beginning, or they may be absorbed by some substance through which the ray passes from the sun to the earth. As Brewster showed long ago, many of the lines are really due to absorption by the earth's atmosphere, and are more marked when the sun is low than when the sun is high. These lines which are certainly due to absorption by the earth's atmosphere are called telluric. Near the Fraunhofer D lines there exists a very remarkable group of lines known as the Rain-band. It is due to water-vapour in the air, and gets very dark as the humidity approaches saturation. The principal lines in the solar spectrum are, however, not telluric. Nor can they be explained as due to the absorptive action of the ether, inasmuch as the various spectra of stars, though broadly similar to that of the sun, differ from it and from one another greatly in detail. (Compare, for example, the spectra of Sirius and of the sun in the table.) In short, solar and stellar spectra are very characteristic in the number and distribution of the lines which cross what is otherwise a continuous spectrum (see STARS). If then these lines are due to absorption, it must be absorption in the atmosphere enveloping each star or sun. That this is the true explanation of the dark lines has been for long regarded as established beyond a doubt.

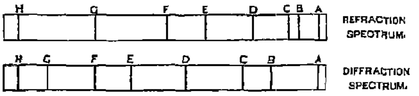

Fig 3.

Previous, however, to the discovery of the principle which lies at the basis of stellar and solar spectroscopy, the great variety of spectra given by different substances had been recognised. Some of these are shown in the accompanying table of spectra; and, as suggested by Talbot and Herschel in 1825, an obvious application of the prism is to the *qualitative* determination of small quantities of substances in minerals. In the accompanying coloured plate, the characteristic spectra of the vapours of ten of the metals taken by themselves may be compared with the very different spectra of the sun, of nitric peroxide, and of Sirius; that of the nebula in Orion almost rivals in simplicity the visible spectrum of sodium vapour. The case of Thallium (q.v.) is of peculiar historic interest, since it was the observation of its very characteristic line spectrum which led to its discovery. Of even greater interest historically is the spectrum of sodium, which may be observed by burning common salt in a spirit-flame. Fraunhofer observed that the two bright yellow lines so characteristic of the sodium spectrum coincided in position with the double line known as D in the solar spectrum. A very careful test of this coincidence was made by Professor Miller, following upon which Stokes (in 1850) gave for the first time the physical explanation of the phenomenon—viz. that the Fraunhofer double D is produced by the absorptive action of sodium vapour in the sun's atmosphere. Foucault (in 1849) had already obtained an evident darkening of the D lines when the ray of sunlight was passed through the electric arc, which gave in its spectrum the bright sodium lines; but he failed to grasp the significance of the experiment. Ten years later Kirchhoff made a similar experiment, and to him we owe the complete statement of the principle on which spectrum-analysis is based. (For the important work of Balfour Stewart in this connection, see HEAT.) The principle is defined by Kirchhoff thus: the ratio of the emissive and absorptive powers for any given radiation is the same for all bodies at the same temperature. If we imagine the existence of an ideal *black body* which is at once a perfect absorber and a perfect radiator, we may, following Tait in his development of Stewart, express the principle in this wise: for any given temperature the emissivity of a radiating body is equal to its absorptivity. Here emissivity is the emissive power of the chosen body compared with that of the ideal black body; and similarly absorptivity is the ratio of the absorptive powers of the chosen body and the black body for the same radiation at the same temperature. Suppose we have a body A exposed to radiation r from a body B. If A were black the whole radiation would be absorbed. As it is, however, the body A will absorb only er, where e is the emissivity. Again, if R is the measure of the radiation which a black body at the temperature of A would radiate, eR will measure the radiation of A. Hence the amount of radiation which reaches us from A, and through A from B, will be $eR + (r - er) = r - e(r - R)$. Hence there will be a real resultant absorption by A as the rays from B pass through it if, and only if, r is greater than R—i.e. in accordance with experience, if B is at a higher temperature than A. The ultimate basis of the argument is the Second Law of Thermodynamics (q.v.); and it should be noted that the principle fails to apply to cases of phosphorescence or fluorescence. Thus we conclude that the Fraunhofer lines in the solar spectrum are due to the absorptive action of the comparatively cool atmosphere of the sun upon the radiation which comes from the hotter interior parts. At the instant of a total eclipse of the sun, when the hot interior is screened off, the spectrum of the cooler but still self-luminous envelope is seen to consist of several bright lines. With the exception of one peculiar line in the yellow, these are all coincident in position with certain of the dark Fraunhofer lines. The most conspicuous of the lines that so become reversed are the four hydrogen lines. The ' '' 'lue to magnesium, the double D, and some on lines have also been observed reversed stant of totality.

'ation of the dark lines in solar and vith the bright lines in the spectra 'lementary substances raised to a high enough temperature is one of the most important labours of the spectroscopist. A list of the elements which have been proved to exist in the solar atmosphere will be found in the article SUN. In fig. 4 a small portion of the sun's spectrum near the b line is given, showing the identification of certain constituents of the sun's atmosphere with iron, magnesium, nickel, and calcium.

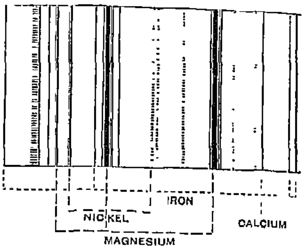

Fig. 4.

The character of the spectrum of a given substance changes with temperature and pressure. For example, although hydrogen, like all gases, gives at ordinary pressures a bright line spectrum with sharp thin lines, these lines become broader and broader as the pressure is increased, until at very high pressures the spectrum becomes almost continuous like that given by a glowing white hot solid. Thus we learn that a highly compressed gas at a high temperature ceases to give the discontinuous bright line spectrum so characteristic of it at low pressures. One tolerably safe conclusion to draw is that stars which all have continuous spectra crossed by dark absorption lines or bands consist of a highly condensed nucleus; whereas true nebulæ, which show bright line spectra (see the table of spectra), are luminous because of the presence of glowing gas in a comparatively attenuated condition. In the case of Comets (q.v.) the spectrum is faintly continuous with bright lines crossing it—a mingling of solar reflected light with the proper gaseous spectrum of the comet itself. The planets give in like manner the spectrum of sunlight modified more or less by the absorptive character of their atmospheres.

If a ray of sunlight, or a ray from the electric or lime light, is passed through various liquids, very characteristic absorption bands are obtained across the otherwise continuous spectrum. For example, arterial and venous bloods give absorption spectra, which are readily distinguishable one from the other. The second spectrum in the plate is an absorption spectrum produced by passing the electric ray through peroxide of nitrogen. It shows the banded characteristics of such spectra.

A very remarkable application of spectrum-analysis is to the measurement of the rate of approach or recession of any heavenly body. If we are approaching a star the waves of light will meet us at a somewhat quicker rate than if we were relatively steady with regard to it. That is, the waves of light will appear to be shorter—hence all the lines in the spectrum will be displaced towards the violet end. On the other hand, if we are receding from the star, the spectrum lines will appear to be shifted towards the red end. For example, in the spectrum of Sirius, the F line is very slightly shifted towards the red by an amount which is measurable in a fine spectroscope. The interpretation is that Sirius is receding from the solar system with a velocity of about 20 miles per second. Arcturus, on the other hand, is approaching our system with a speed of 55 miles per second. Similar displacements of lines are observed in the spectra of certain sun-spots, which are thereby proved to consist of downrushes of gas.

Throughout this article we have confined our attention to the *visible* part of solar spectrum. But this extends much further than is apparent to the eye. Below the red are the dark heat rays, whose presence or absence can be demonstrated by the appropriate means. Professor Langley has specially studied this region with the aid of rock-salt prisms and the Bolometer (q.v.), and has carefully measured the positions of the absorption bands. Captain Abney has, by use of a special preparation of bromide of silver, obtained photographs of the infra-red end of the spectrum, and has identified some of the absorption lines with lines in the spectra of metals of low melting points, such as sodium and calcium. Metals which volatilise at high temperatures do not seem to give lines below the red. Above the visible violet again are the invisible actinic rays. This upper part of the spectrum can be made visible by allowing it to fall upon some suitable fluorescent substance, such as uranium glass or a solution of sulphate of quinine. Photography, however, supplies us with a perfect method for obtaining visible images of the actinic spectrum. Indeed, by properly choosing the sensitive substance, we can now photograph any part of the spectrum from a radiation of nearly four times the wave-length of the red rays up to the highest actinic rays known to exist; and in the extended solar spectrum so obtained we find the same characteristics throughout—a continuous spectrum crossed by dark lines.

Schellen's *Spectralanalyse* (2 vols. 3d ed. 1883; Eng. trans. 1885), with *Atlas* of spectra, is the most complete treatise on the subject. See also Lockyer's *Studies in Spectrum Analysis* (Inter. Sc. Series, 2d ed. 1886).

Specular Iron. See IRON, Vol. VI. p. 215.

Speculum Metal, an alloy used for the specula or mirrors of reflecting telescopes. The best is composed of 126 parts of copper and 58·9 of tin. It takes a fine polish and is not easily tarnished unless exposed to damp. Glass with a film of metallic silver deposited upon it is now taking the place of speculum metal for these mirrors. The silvered glass is equally serviceable and less costly. See TELESCOPE.

Spedding, JAMES, was born at Mirehouse, near Bassenthwaite, in June 1808, the younger son of a Cumberland squire. From Bury St Edmunds, where he was head of the school, he proceeded in 1827 to Trinity College, Cambridge, of which he became a scholar, and of which too at his death he had long been an honorary fellow. Still, brilliant scholar though he was, his degree was only a second-class in classics and junior optime. From 1837 to 1841 he held a post at the Colonial Office; in 1842 he accompanied Lord Ashburton (q.v.) to America as private secretary; and in 1847 he might, had he chosen, have become Under-secretary of State, with £2000 a year. But he had already devoted himself to the task of his life—'to re-edit Bacon's Works, which did not want any such re-edition, and to vindicate his character, which could not be vindicated.' So writes Edward Fitz Gerald, the oldest of Spedding's many brilliant friends—Tennyson and Carlyle were also of the number—and he adds: 'He was the wisest man I have known; not the less so for plenty of the boy in him; a great sense of humour; a Socrates in life and death, which he faced with all serenity so long as consciousness lasted.' That death was in St George's Hospital, on 9th March 1881, Spedding having eight days before been run over by a cab.

His publications were *Works, Life, and Letters of Bacon* (14 vols. 1857-74); *Publishers and Authors* (1867); *Account of the Life and Times of Bacon* (2 vols. 1878); *Reviews and Discussions not relating to Bacon* (1879); *Studies in English History* (1881), in conjunction with J. Gairdner; and *Evenings with a Reviewer* (relating to Bacon, 2 vols. 1881). See the brief Memoir by G. S. Venables prefixed to the last, and also Fitz Gerald's *Letters* (1889).

Speech. See ADAM, DUMBNESS, PHILOLOGY, PHONETICS, VISIBLE SPEECH, VOICE.

Speed, JOHN, antiquary, was born at Farington in Cheshire in 1542, worked most of his days at London as a tailor, and died July 28, 1629, being buried in St Giles's, Cripplegate. All his life long he had been acquiring historical learning, and his extraordinary attainments at length gained him the acquaintance of Sir Fulke Greville and others, and hence opened up a door for the publication of the great works through which his name survives. These are *Maps* (54) *of England and Wales* (1608-10; incorporated into *The Theatre of the Empire of Great Britain*, 1611); *The History of Great Britain under the Conquests of the Romans, Saxons, Danes, and Normans* (1611). His theological writings are of no importance.

Speedwell (*Veronica*), a genus of plants of the natural order Scrophulariaceæ, distinguished by a four-cleft wheel-shaped corolla, with the lower segment narrower, two stamens, and a two-celled capsule. The species are very numerous, annual and perennial herbaceous plants and small shrubs, natives of temperate and cold climates in all parts of the globe. Some of them grow in wet ditches and in marshes, some only on the driest soils. They have generally very beautiful blue, white, or pink flowers. The number of British species is considerable, and few wild-flowers are more beautiful than the Germander Speedwell (*V. chamædrys*), or the alpine species, *V. alpina* and *V. saxatilis*. A number of species are very generally cultivated in flower-gardens. The bitter and astringent leaves of the Common Speedwell (*V. officinalis*), one of the most abundant British species, found also in almost all the northern parts of the world, are in some countries used as a tonic, sudorific, diuretic, and expectorant medicine. They are also employed, particularly in Sweden, as a substitute for tea, as are those of the Germander Speedwell. *V. virginica* is called *Culver's Physic* in North America; it is said to be actively diuretic, and a decoction of the fresh root is violently cathartic and emetic. Brooklime (q.v.) belongs to this genus. Several of the shrubby species of Veronica of peculiar and ornamental character, natives of the mountains of New Zealand, are now plentiful, and prove perfectly hardy, in British gardens.

Common Speedwell (*Veronica officinalis*).

Speier. See SPIRES.

Speiss. This name is given to the product first obtained (an arsenide of the metal) when arsenical ores are smelted. See NICKEL.

Speke, JOHN HANNING, an explorer of Africa, was born on 4th May 1827 at Jordans in Somersetshire, entered the Indian army when seventeen, and saw some active service in the Punjab. During peace he spent great part of his time in making shooting expeditions into the Himalayas, in the course of which he collected natural history specimens and did a good deal of route-plotting. In 1854 he joined Burton in an excursion into the Somali country, and barely got back with his life. Three years later the Royal Geographical Society sent out the same two travellers to search for the great equatorial lakes of Africa. Speke, whilst travelling alone, discovered the Victoria Nyanza, and was convinced that it was the head-waters of the Nile. In 1860 he returned in company with Captain J. A. Grant (q.v.; died 10th February 1892), and not only explored the western and northern shores of the large lake he had previously discovered, but followed the Nile far enough down its course to establish its identity with the great river of Egypt. Nevertheless his identification was disputed by Burton and others; and Speke was to hold a public discussion with Burton at the British Association meeting at Bath on 15th September 1864, when, on that very morning, he accidentally shot himself whilst out shooting near that city. He wrote *Journal of the Discovery of the Source of the Nile* (1863), and *What led to the Discovery of the Source of the Nile* (1864).

Spell. See INCANTATION.

Spelling is originally phonetic, its aim to convey to the eye the sound heard by the ear; but in modern English the usage of pronunciation has drifted far from the conventional forms established by a traditional orthography, with the result that the present spelling of our written speech is to a large extent a mere exercise of memory, full of confusing anomalies and imperfections, and involving an enormous and unnecessary strain on the faculties of learners. The modern English alphabet consists of twenty-six letters, of which five are vowels, and of these not even the consonants are consistent in sound, as may be readily seen in the current pronunciation of such words as *give, gin; cent, cant; thin, this; cough, dough; sough, hiccough, hough; loch, arch, patriarch.* Some again are superfluous, as hard *c, q, x,* their sounds being capable of being represented by other letters; while others remain silent in pronunciation, as seen in *through, plough, debt, knell, write, lamb, malign, demesne, trait.* Further anomalies appear in *walk, folk* as opposed to *malt, fault;* while a stranger series still appear in such words as *colonel, lieutenant, foreign, scent, island, scythe, scissors, rhyme, ache, sceptic.* Again, the same vowel or diphthong meets us in such varying forms as the following (from Mr Lounsbury's lists): the short *e* variously in met, sw*ea*t, *a*ny, s*ai*d, s*ay*s, j*eo*pardy; the long *e* in m*ee*t, mete, m*ea*t, mach*i*ne, gr*ie*f, rec*ei*ve, k*ey*, qu*ay*, p*eo*ple, *æ*gis. Again, take the varying forms of the same vowel-sound in r*u*de, r*ue*d, r*oo*d, r*ou*tine, rh*eu*m, dr*ew*, sh*oe*, m*o*ve, br*ui*se; while on the other hand six different sounds have the same form in *sour, pour, would, tour, sought, couple;* and five in *heat, sweat, great, heart, heard.* Groups of words like *man, lane, ask, salt* on the one side, and *why, wine, eye, lie,* or *air, heir, eyre, ere, e'er* on the other, show equally a violation of the fundamental principle of all rational spelling—viz. that of representing every sound by an invariable symbol.

Examples enough have been given to demonstrate the utterly unscientific character of English spelling; it now remains to ask how this has originated, and whether any measure of relief from such a burden is practicable. It was only slowly that this modern uniformity became rigid, and we may dismiss as completely without foundation the defence put forward by pre-scientific philologists like Trench that the modern spelling is valuable as preserving an index to the derivation. Even if this were true, are we justified in paying so great a price for an end so little? But when we look at the facts we find that if the conventional spelling in some few cases preserves a hint as to the ultimate origin, as in *aunt, newt, knave, debt,* it is far more often the case that it obscures the order of descent, or merely preserves the memory of some error through false analogy or sheer ignorance, as in words like *shamefaced, rhyme, comptroller, isinglass, whole, bridegroom, stark-naked, battledoor, belfry, taffrail, spruce-beer.* Again, the infallible writers for the press talk with indignation of being divorced from the tongue of Shakespeare and the Bible; but, as Dr Murray says, the slightest glance at 17th-century orthography will show what an immense amount of spelling reform has been done since then. Thus Psalm cvi., as printed in 1611, differs in 116 spellings from that printed in 1892; the first chapter of Genesis, in 135 spellings. One of the most important spelling reforms in English was that made about 1630 when *u* was made a vowel and *v* a consonant, for up to that time these were only forms of the same letter having a position-rank like long *ſ* and short *s*. From the 14th century onwards a fashion grew of adapting the spelling of words to their supposed Latin originals, with what confusion to the real history of the words may be imagined from the accidental or capricious errors of sciolists innocent of scientific method. But generally speaking up to the 16th century English spelling was mainly phonetic like the present German. The old scribes allowed themselves large liberty in the forms they adopted, to which Chaucer refers in the well-known lines, 'and for there is so great diversite in English, and in writing of our tong.' The *Ormulum* is an interesting example of a consistent attempt at a phonetic spelling. But as literature developed and the printing-press began to assert its authority the spelling became more and more fixed, till at last it became quite stationary, while the pronunciation continued to go on changing without intermission until, as Mr Sweet says, our present spelling does not represent the English we actually speak, but rather the language of the 16th century. This progress towards uniformity went on actively during the 17th century, but it was Johnson's *Dictionary* (1755) that gave universality to the currency. Meantime spoken language grew, and natural divergencies arose, resulting in the modern pronouncing dictionary, which Trench called with justice 'the absurdest of all books.'

Halliwell tells us Shakespeare spelt his name in some thirty different forms; the young Pretender writes of his father indifferently as Jems or Gems; Claverhouse, says Macaulay, spelt like a washerwoman; and the great Marlborough used the same freedoms as Thackeray's Jeames or the ordinary Englishman whose education stopped short for ever at the Fourth Standard. But we may remember that Will Honeycomb never liked pedantry in spelling, and spelt like a gentleman, not like a scholar. And we must not suppose that great as was Johnson's influence all his spellings have been accepted. His *musick, ambassadour, horrour, cimeter, waterfal, parsnep, skeptick, sackcloath,* have disappeared; but some of his strange pairs of inconsistencies survive: *moveable* and *immovable, chilifactory* and *chyle, bias* and *unbiassed.* Similar are *recognize* and *surprise, confer* and *conferred, worship* and *worshipper.* Webster in his 1828 edition gives us many original spellings, as *melasses, pretense, bridegoom,* all of which were swept away in the revision of 1864. Julius Hare and Thirlwall adopted such forms as *forein, soverein, cherisht, preacht,* from one-sided considerations of philology; Ritson's habit of adding *-ed* to the preterite of all verbs was but one among many of the whimsical notions of a half-crazy antiquary; Pinkerton's vagaries are beneath notice; the usages familiar to readers of Mr Furnivall's 'fore-words' belong to quite another category, and might be commended altogether, but for the saving caution of Mr Sweet that 'nothing can be done without unanimity, and until the majority of the community are convinced of the superiority of some one system unanimity is impossible.' For spelling reform must proceed by a wise moderation, and Englishmen as yet are far from being ready for such elaborate systems as the Glossic of Mr Ellis, the Romic of Mr Sweet, or even the Phonetik type which Mr Pitman has been bravely printing for fifty years. But to these scholars the cause owes all the progress it has made, and their names will live in honoured memory when rational principles at last prevail over the tremendous forces of inertia and prejudice. It is hard to reason men out of beliefs they have never been reasoned into, and it may yet be long before our children are relieved of an unnecessary burden too heavy to be borne. That we can still read Chaucer and *Piers Plowman* despite Johnson's *Dictionary* should dispose of the one specious difficulty objected to reform; another—viz. that uniformity would confound such homonyms as *write*, *rite*, *right*, and *wright*—is answered by the fact that the identity of sound troubles us little in speaking, and would trouble us still less in reading, with the help of the context before us. Meantime the true path of progress should follow such wisely moderate counsels as those of Dr Murray: the dropping of the final or inflexional silent *e;* the restoration of the historical *-t* after breath-consonants; uniformity in the employment of double consonants, as in the American *traveler*, &c.; the discarding of *ue* in words like *demagogue* and *catalogue;* the uniform levelling of the agent *-our* into *-or*, already so common in America; the making of *ea* = *ĕ* short into *e* and the long *ie* into *ee;* the restoration of *some, come, tongue*, to their old English forms, *sum, cum, tung;* a more extended use of *z* in the body of words, as *chozen, praize, raize;* and the correction of the worst individual monstrosities, as *foreign*, *scent*, *scythe*, *ache*, *debt*, *people*, *parliament*, *court*, *would*, *sceptic*, *phthisis*, *queue*, *schedule*, *twopence-halfpenny*, *yeoman*, *sieve*, *gauge*, *barque*, *buoy*, *yacht*, &c.

An encouraging success is the improvement of German spelling, introduced in 1880, the chief features of which are the omission of all superfluous signs indicating the lengthening of a syllable, the substitution of *f* for *ph*, the determination of the sound of *s* hard and soft, the use of *sz*, the doubling of consonants, the retention of *h* as indicating vowel-lengthening only in root-syllables: *Akt*, *Armut*, *Elefant*, *tot*, *Irrtum*, *Wert*.

Spelman, SIR HENRY, antiquary, was born in 1562, son of a gentleman of ancient family, at Congham in Norfolk. He was educated at Trinity College, Cambridge, whence he passed to Lincoln's Inn. He was high-sheriff of Norfolk in 1604, and was often employed in public affairs at home and in Ireland by James I. Knighted by the king, he retired in 1612 to prolonged private studies, and died in 1641. His ponderous *Glossarium Archæologicum*, of which he published A—L in 1626, was completed by his son, Sir John Spelman, and William Dugdale. His next great work, *Concilia, Decreta, Leges, Constitutiones in Re Ecclesiastica Orbis Britannici* (1639–64), he also left incomplete. His other works on Tithes, on Sacrilege, are no less learned, and exhibit his strong devotion to the Church of England. His *Reliquiæ Spelmannianæ* were edited, with a Life, by [Bishop] Edmund Gibson (1698).—His eldest son, SIR JOHN SPELMAN, inherited all his tastes and part of his learning. He was knighted in 1641, and died in 1643, author, besides other works, of a life of King Alfred (in Lat. trans. 1678; Spelman's Eng. original, edited by Thomas Hearne, 1709).

Spence, JOSEPH, anecdotist, was born at Kingsclere in Hants, 25th April 1699. A sickly boy, he went to Eton, but in a short time left it for Winchester, thence passing to New College, Oxford, in 1720, of which he became a fellow in 1722. He took orders in 1724, three years later became professor of Poetry, and was presented to the rectory of Birchanger in Essex. He travelled on the Continent with the Earl of Middlesex, afterwards second Duke of Dorset (1730–33), again with Mr Trevor (1737), and Henry, Earl of Lincoln, afterwards Duke of Newcastle (1739–42). Before first going abroad he had published his *Essay on Pope's Odyssey* (1726), which procured him the lasting friendship of the poet. Almost from the beginning of their intimacy he began to record Pope's conversation and the incidents of his life, to which gradually many curious particulars were added gathered from the conversation of other eminent men. In 1736 he edited *Gorboduc*, and in 1737 became rector of Great Harwood in Bucks, and regius professor of Modern History. In 1747 he published his *Polymetis*, which is said to have brought him £1500, great part of which he spent on landscape-gardening at Byfleet in Surrey. In 1754 he became a prebendary of Durham. He was accidentally drowned at Byfleet, August 20, 1768. He was a constant friend to Pope, Horace Walpole, Shenstone, and Lowth, and was noted for his large charity, a devoted love to his aged mother that rivalled Pope's own, and his kind patronage of such men as Stephen Duck, thresher and poet; Robert Hill, the learned tailor; Thomas Blacklock, the blind poet; and Robert Dodsley, footman before publisher.

His MS. collection of Anecdotes was given by his executors to the Duke of Newcastle, who did not approve of their being published. Some, however, reached the public through Warburton, Warton, Johnson, and Malone—in the case of the first two from Spence himself. Malone's edition (1820) was quickly superseded by that of S. W. Singer (1820; 2d ed. 1858), printed from the original papers, with notes and a memoir.

Spencer, a town of Massachusetts, 64 miles by rail W. by S. of Boston, with several manufactories of boots and woollens. Pop. (1890) 8747.

Spencer, a family which has given several statesmen to the service of their country, was founded by the Hon. John Spencer, youngest son of the third Earl of Sunderland, by Anne, daughter and co-heiress of the great Duke of Marlborough. He inherited much property from his grandmother, Sarah, Duchess of Marlborough, and his only son, JOHN (1734–83), was made Earl Spencer in 1765.—GEORGE JOHN, second Earl (1758–1834), was First Lord of the Admiralty under Pitt's administration (1794–1801), the period of the great naval victories of Camperdown, Cape St Vincent, and the Nile. He retired when Addington became premier, and was famous as a munificent collector of rare books and the first president of the Roxburghe Club. The Spencer Library, dispersed under the hammer in 1881–83, brought £50,581.—JOHN CHARLES, third Earl Spencer, better known under the courtesy title of Lord Althorp, was born in 1782, and educated at Harrow and Trinity College, Cambridge. He entered parliament in 1804 for Oakhampton, and became a junior Lord of the Treasury when in 1806 his father took office as Secretary of State for the Home Department in the Grenville-Fox ministry. He sat for Northamptonshire from this time till the Reform Bill, and in the Reformed parliament for the southern division of the county. He went out with the Whigs in 1807, and gave steady opposition during the long Tory reign thereafter. On the dissolution of the Wellington cabinet in November 1830 he became Chancellor of the Exchequer and leader of the House of Commons in the celebrated Reform ministry of Earl Grey. The Reform Bill was introduced by Lord John Russell, but the task of carrying the bill mainly devolved upon Spencer. In 1833 he brought in and carried the ministerial bill for reforming the Irish Church. In this memorable working session the curious statistician discovered that Spencer, who had, from his post of ministerial leader, naturally been the most frequent speaker, had addressed the House 1026 times, his speeches occupying 387 columns in the then *Mirror of Parliament*. When the Irish Coercion Bill was under consideration in the cabinet Spencer had opposed the clauses prohibiting public meetings, yet had given way rather than break up the ministry, but when the truth was elicited in debate by Mr O'Connell he resigned. He was considered and described by Earl Grey as his 'right-hand man,' and without his assistance the earl felt himself unable to carry on the government. The administration of Viscount Melbourne succeeded (July 1834), in which Spencer consented to resume his office. In November he was called by the death of his father to the House of Peers, which had the effect of bringing the Melbourne administration to an end. When the attempt of Sir Robert Peel to carry on the government failed Spencer declined to take office again. He devoted his time to agricultural pursuits, became president of the Smithfield Cattle Club, and suggested the formation of the Royal Agricultural Society, of which he was elected president in 1838. He died at his seat, Wiseton Hall, Notts, October 1, 1845, without issue, and was succeeded by his brother. During his political career his simplicity of character and integrity of purpose obtained for him the appellation of 'honest Lord Althorp.' He was very little of an orator, but he had a clear and practical intellect, and his influence over the Reformed House of Commons was supreme. Lord Brougham dedicated to him his work on *Natural Theology*; and his *Dialogues on Instinct* are also supposed to be carried on with Spencer, to whose cultivation of philosophy in the midst of his political and agricultural pursuits the author bears friendly testimony. See *Memoir* by Sir Denis Le Marchant, Bart. (1876), Walter Bagehot's *Biographical Studies* (1881), and Ernest Myers' *Lord Althorp* (1890).—JOHN POYNTZ SPENCER, fifth earl, was born October 27, 1835, and was educated at Harrow and Trinity College, Cambridge. He had sat but a few months in the House of Commons for South Northamptonshire when the death of his father in 1857 sent him to the House of Lords. He was Lord-lieutenant of Ireland from 1868 to 1874, in 1880 became Lord-president of the Council, and during 1882-85 was Lord-lieutenant of Ireland. In the short-lived government of 1886 he was again President of the Council. He embraced Mr Gladstone's Home Rule policy, having during his tenure of office at Dublin Castle come to the conclusion that coercion was a failure.

Spencer, HERBERT, who has attempted to work out a complete system of philosophy in harmony with evolution and the results of modern science, was born at Derby, 27th April 1820. His father was a schoolmaster in that town, and secretary of the Philosophical Society; and from him Spencer imbibed that love of natural science and wonderful faculty of observation so conspicuous in his works. The father was greatly interested in entomology; and Spencer himself used to collect, describe, and draw insects when a boy. Insurmountable aversion to linguistic studies put a Cambridge career out of the question, and at the age of seventeen he entered upon the profession of a railway engineer under Mr (afterwards Sir Charles) Fox, in London; but about eight years afterwards he gave up this profession, which lacked interest for him. He had already contributed various papers to the *Civil Engineers' and Architects' Journal*; and in the later half of 1842 he wrote a series of letters to the *Nonconformist* newspaper on 'The Proper Sphere of Government,' which were republished in pamphlet form in 1843. These letters imply a belief in human progress based on the modifiability of human nature through adaptation to its social surroundings, and maintain the tendency of these social arrangements 'of themselves to assume a condition of *stable* equilibrium.' From 1848 to 1853 he was sub-editor of the *Economist* newspaper; and at this time he developed the ethical and political consequences of the ideas he had already enunciated, and sought an independent basis for them. Hence his first important work, *Social Statics* (1850; abridged and revised, 1892). It is thus noticeable that Spencer's philosophical activity began with ethical and social questions. The conception of the evolution of man and society as determined by circumstances, and the idea that organic and social evolutions are under the same law, *preceded* the elaboration of those scientific ideas which, in the complete *System of Philosophy*, are made to serve as their basis. The truth anticipated by Harvey and Wolff, but first put into definite shape by Von Baer—'the truth that all organic development is a change from a state of homogeneity to a state of heterogeneity'—is regarded by Spencer as the organising principle of his subsequent beliefs. It was gradually developed and applied by him in a series of articles contributed in the following years to the *Leader*, the *North British*, *British Quarterly*, *Medico-Chirurgical*, *Westminster*, and other reviews.

In these essays, especially those on *The Development Hypothesis* (1852), *Manners and Fashion* (1854), *The Genesis of Science* (1854), and *Progress: its Law and Cause* (1857), and in the volume of *Principles of Psychology* (1855), the doctrine of evolution began to take definite form, and to be applied to various departments of inquiry. The publication of Darwin's *Origin of Species*, in 1859, gave a wide basis of scientific proof for what had hitherto been matter of speculation, and first showed the important part played by natural selection in the development of organisms.

In 1864 Spencer published an essay on the *Classification of the Sciences*, in which he criticised Comte's serial arrangement of the sciences according to generality, and substituted for it a classification according to abstractness: (1) *Abstract Science*, treating of the forms (space and time) in which phenomena are known to us—logic and mathematics; (2) *Abstract-concrete Science*, treating of the laws of the factors of the phenomena themselves—mechanics, physics, chemistry, &c.; (3) *Concrete Science*, treating of the phenomena in their totalities (the laws of the products)—astronomy, geology, biology, psychology, sociology, &c.

Upon this scheme of the sciences Spencer had now been working for several years. As early as 1860 he had announced the issue of a *System of Synthetic Philosophy*, already in course of preparation, which, beginning with the first principles of all knowledge, proposed to trace how the law of evolution was gradually realised in life, mind, society, and morality. In pursuance of this comprehensive design Spencer has published *First Principles* (1862); *Principles of Biology* (2 vols. 1864–67); *Principles of Psychology* (2d ed. 2 vols. 1870–72); *Principles of Sociology* (vol. i. 1876); 'Ceremonial Institutions' (1879), and 'Political Institutions' (1882), composing vol. ii.; 'Ecclesiastical Institutions,' being part i. of vol. iii. (1885); 'Data of Ethics,' being part i. of *Principles of Ethics* (1879); 'Justice,' being part iv. of the same work (1891); and parts ii. and iii. completing vol. i. (1892).

These works follow a different plan from his earlier writings. In his occasional essays already referred to he proceeded by means of observation and induction; and in them the law of evolution was the result of a generalisation. But the method of his *System* is deductive; though the deductions, large and small, are always accompanied by inductive verifications. Even the law of evolution only finds a place in it because it can be deduced from a higher and ultimate principle. Just as certain special sciences—mechanics, for example—have already entered into the deductive stage, so, in Spencer's *System*, completely coordinated knowledge, to which he gives the name of philosophy, becomes deductive. Hence the importance of determining what is the ultimate test of truth. This, according to him, is the mental inconceivability of the negation of the proposition by the individual thinker. The validity of this test is supported, according to him, by two considerations: first, because no other test is obtainable, and secondly, by the consideration that mental inconceivability is the result of certain uniformities in our experience which are due to uniformities in nature. His appeal to this test, and the way in which he employs it, formed the subject of a controversy with J. S. Mill, and brings out the distinction between his method and principles and those of the empirical philosophy.

Metaphysically, Spencer's system is founded on the doctrine of relativity deduced by Hamilton and Mansel from Kant, but carried by him, as he says, a step further. Along with the definite consciousness of things known in relation to one another there is implied an indefinite consciousness of an absolute existence, in the recognition of which as inscrutable science and religion find their reconciliation. All definite consciousness or knowledge is of the manifestations of this unknowable power; and knowledge, completely unified, is philosophy. The data of philosophy are necessarily those organised components of our intelligence without which philosophising could not go on. 'Our postulates are: an unknowable power; the existence of knowable likenesses and differences among the manifestations of that power; and a resulting segregation of the manifestations into those of subject and object.' Within each segregated mass there are likenesses and differences involving secondary segregations. The modes of cohesion under which manifestations are invariably presented are called, when contemplated apart, space and time; when contemplated along with their manifestations, matter and motion. All these are traceable to experiences of that mode of consciousness whose reality is shown by its persistence—to force. By the 'persistence of force' is meant the unchanging quantity both of that mode of force which is revealed to us only by opposition to our own powers, and is not a worker of change, and of that mode which is a worker of change actual or potential, and is specifically termed energy. The persistence of force—i.e. the persistence of some cause which transcends our knowledge and conception—is the truth which all other truths imply, and from which they all (including the law of evolution) are derived. From the fact that force can neither arise out of nor lapse into nothing follows the uniformity of law. Force never disappears; it is only transformed. Motion follows the line of least resistance, and is perpetually reversed within limits—is rhythmical. So far of the factors of phenomena. The phenomena themselves must be under a law of the concomitant redistribution of matter and motion, which holds of every change. The law of the entire cycle of changes passed through by every existence is loss of motion and consequent integration—i.e. evolution, eventually followed by gain of motion and consequent disintegration—i.e. dissolution. In its complete shape the 'formula of evolution' is thus stated: '*Evolution is an integration of matter and* concomitant dissipation of motion; during which the matter passes from an indefinite incoherent homogeneity to a definite coherent heterogeneity; and during which the retained motion undergoes a parallel transformation.' This law of evolution applies equally to all orders of phenomena—'astronomic, geologic, biologic, psychologic, sociologic, &c.'—since these are all component parts of one cosmos, though distinguished from one another by conventional groupings. So long as evolution is merely established by induction it does not belong to philosophy. It must be deduced from the persistence of force. And this can be done. For any finite aggregate being unequally exposed to surrounding forces will become more diverse in structure; every differentiated part will become the parent of further differences; at the same time, dissimilar units in the aggregate tend to separate, and those which are similar to cluster together ('segregation'); and this subdivision and dissipation of forces, so long as there are any forces unbalanced by opposite forces, must end at last in rest; the penultimate stage of this process, 'in which the extremest multiformity and most complex moving equilibrium are established,' being the highest conceivable state.

The various derivative laws of phenomenal changes are thus deducible from the persistence of force, and it remains to apply them to inorganic, organic, and super-organic existences. The detailed treatment of inorganic evolution is omitted from Spencer's plan (which is, he remarks, even too extensive without it), and he proceeds 'to interpret the phenomena of life, mind, and society, in terms of matter, motion, and force.'

It is impossible to give here any but the most general idea of the contents of the volumes in which the law of evolution is applied to these different departments. It is not only made to account for the phenomena within each group, but also for the connection between one science and another. The researches of Darwin had accumulated ample material for showing the continuity of development, structural and functional, in plants and animals; and Spencer's view of biology, and the definition of life he proposes ('the definite combination of heterogeneous changes both simultaneous and successive in correspondence with external co-existences and sequences'), are meant to show its connection both with inorganic changes on the one hand and with mind on the other. Now, just as biology has to deal with the connection between phenomena in the organism, and as physical science treats of the connection between phenomena in the environment, so psychology has to do with the connection between these two connections. For this is said to be the objective aspect of what states of consciousness are subjectively. The functions dealt with by the psychologist are more special than those dealt with by the biologist; but they belong to psychology, not merely because they are more special, but also because they are the counterparts of the states of consciousness dealt with by the science of subjective psychology.

Objectively, an attempt is made to trace the evolution of mind from reflex action through instinct to reason, memory, feeling, and will, by the inter-action of the nervous system with its environment. Subjectively, mental states are analysed, and it is contended that all of them—including those primary scientific ideas, the perceptions of matter, motion, space, and time, assumed in the *First Principles*—can be analysed into a primitive element of consciousness, something which can only be defined as analogous to a nervous shock. These perceptions have now become innate in the individual. They may be called—as Kant called space and time—forms of intuition; but they have been acquired empirically by the race, through the persistence of the corresponding phenomena in the environment, and from the accumulated experiences of each individual being transmitted in the form of modified structure to his descendants.

This principle of heredity is one of the laws by which individuals are connected with one another into an organic whole; and we thus pass quite naturally to what Spencer calls super-organic evolution, implying the co-ordinated actions of many individuals, and giving rise to the science of sociology. Society, like an individual man, is shown to be an organism from the fact and laws of its growth, the nature of its activities, and the inter-dependence of its parts; though it is distinguished from the individual organism in this, that it is discrete, while the latter is concrete: 'there is no social sensorium.' As societies progress in size and structure, they work on one another profound metamorphoses, now by war-struggles and now by industrial intercourse.

Assisted by a series of elaborate ethnographical charts (*Descriptive Sociology*) prepared under his direction, Spencer has attempted to trace the development of human ideas, customs, ceremonial usages, and political institutions. The genesis of religion is traced to Ancestor-worship (q.v.), or generally to worship of the dead. The notion of another life—from which the notions of gods and God are gradually evolved—is originated mainly by 'such phenomena as shadows, reflections, and echoes'—these being looked upon as indications of a 'double' or other self, which is not extinguished with the death of the first self. It is this fear of the dead which is the root of the religious control, just as it is the fear of the living which is the root of the political control. Ceremonies and institutions alike have their root in this fear of the stronger and submission to the conqueror. Thus, early communities being of the predatory or militant type, tended to centralised control; while industrial communities, which are now most frequent, should tend to free institutions and to the restriction of the sphere of government to the negative duty of preventing the interference of one individual with his neighbour's liberty. This principle of government—commonly expressed by the maxim *laissez faire*—is energetically enforced by Spencer, against the tendency of much recent legislation. A still higher type than the industrial is possible in the future, by inverting the belief that life is for work into the belief that work is for life; just as the industrial type inverts the belief that individuals exist for the state into the belief that the state exists for individuals.

The principles of morality are looked on by Spencer as the copestone of his system, all his other investigations being only preliminary to them. Ethics, he holds, has its root in physical, biological, psychological, and social phenomena, for by them the conditions of human activity are prescribed and supplied. The best conduct is that which most fully realises evolution—which promotes the greatest totality of life in self, offspring, and the race—the balance of egoism and altruism being attained by a compromise between these contending principles. The measure of life is said to be pleasure, but the Utilitarian school are at fault in assuming that the end (greatest happiness) is better known than the means to it (morality); and in ignoring the fact that accumulated experiences of utility have become consolidated in the superior races into a moral sense.

In the above summary it has been impossible to give any idea of either the strength or weakness of the proof by which this elaborate system is supported. In general, it may be said that its strength lies in the author's brilliant power of generalisation, his acquaintance with many departments of science, and his unsurpassed wealth of illustration. The wide knowledge which all his writings display of physical science, and his constant endeavour to illustrate and support his system by connecting its positions with scientific facts and laws, have given his philosophy great currency among men of science—more so, indeed, than among philosophical experts. At the same time, not only have the development and application he has given to the theory of evolution profoundly influenced contemporary speculation and the recent developments of psychology and ethics, but he must also be regarded as one of the very few modern thinkers who have carried out the attempt to give a systematic account of the universe in its totality. The high opinion of his writings formed by foreign contemporaries has led to many academic honours being pressed upon him, which have, however, all alike been declined.

Spencer's most popular works have been a small volume on *Education* (1861), which has been translated into many languages, and *The Study of Sociology* (1872), which points out to the unscientific reader the difficulties of a social science. He has also written *The Man versus the State* (1884), and *The Factors of Organic Evolution* (1887). His occasional papers have been collected and published in three volumes of *Essays: Scientific, Political, and Speculative. An Epitome of the Synthetic Philosophy*, by F. Howard Collins, was published with Mr Spencer's authority in 1889 (1 vol.); there are criticisms of the system by Guthrie (1879 and 1882) and M'Cosh (New York, 1885); and the *Outlines of Cosmic Philosophy*, by John Fiske (2 vols. Boston, 1874), is based on Spencer's system. See also Fischer, *Ueber das Gesetz der Entwickelung mit Rücksicht auf Herbert Spencer* (1875); Michelet, *Spencers System der Philosophie* (1882); and *Spencers Lehre von dem Unerkennbaren* (Leip. 1891).

Spencer, WILLIAM ROBERT, minor poet, was second son of Lord Charles Spencer, himself the second son of that Charles Spencer, fifth Earl of Sunderland, who succeeded as third Duke of Marlborough in 1733. He was born in 1770, was educated at Harrow and Oxford, held a Commissionership of Stamps, spent his last ten years in Paris, and died there in 1834. Among his children were Aubrey-George Spencer, Bishop of Jamaica, and George-John-Trevor, Bishop of Madras. He was long a fashionable writer of *vers de société* and such like, but his fashionable verse is clean forgotten, and his name lives alone in a few simple songs and ballads, the chief 'Beth Gêlert, or the Grave of the Greyhound.' Yet even these are but commonplace. His poems were collected, with a brief Memoir, in 1835.

Spencer Gulf, a deep inlet on the coast of South Australia, between Eyre's Peninsula on the W. and Yorke Peninsula on the E. It is 180 miles in length, by 90 in greatest breadth.

Spence's Metal is made by melting together a metallic sulphide, such as sulphide of iron (iron pyrites), along with sulphur. The result is a grayish-black substance, without metallic lustre, which takes a good polish. It can be coloured to imitate bronze and other metals, and as it melts at 320° F. it can readily be cast into moulds from which it takes a sharp impression. Busts, medallions, &c. have been made of it, and it is also used like lead for the joints of pipes. It is but slightly acted on by acids. First made in 1879, it is more of the nature of a hard cement than a metal.

Spener, Philipp Jakob, an illustrious German reformer, and the founder of the movement known as *Pietism*, was born at Rappoltsweiler in Upper Alsace, January 13, 1635. Pious from his cradle, he studied at Strasburg, where in Johann Schmid he found his 'father in Christ.' Next he studied under the younger Buxtorf at Basel, afterwards visiting Geneva, Stuttgart, and Tübingen. In 1663 he became a preacher at Strasburg, and three years later was transferred to Frankfort, and here he laboured with the most devoted zeal to reawaken the dormant and mechanical Christianity of the day by constant catechising and earnest preaching based on Scripture and Christian experience. Yet Spener was the very opposite of what is commonly called a mystic. The devotion which he sought to excite was not to show itself in transcendental ecstasies, but in acts of piety, humility, and charity. He had a strong aversion to formal theology, which he considered a hateful caricature of the free word of life; and he commenced in the year 1670, at his house, meetings for the cultivation of evangelical morality. Out of these grew the famous *collegia pietatis*, whose influence for good on the German character, in those days of stony and barren orthodoxy, cannot easily be overvalued. His earnest and plain-spoken *Pia Desideria* (1675) spread the movement far beyond the range of his personal influence, but aroused the enmity of many in high places. In 1686 he became court preacher at Dresden and member of the Upper Consistory. Here he infused new life into the theological teaching of the university of Leipzig, despite the opposition of Carpzov and others; but, having in 1689 rebuked the Elector Johann Georg III. for his vices, he soon found his position so intolerable that he gladly accepted an invitation to Berlin to become Provost of the church of St Nicholas and consistorial inspector, offices which he retained to the end of his life. The Elector of Brandenburg encouraged his efforts after religious reform, and entrusted theological instruction in the new university of Halle to Franke, Breithaupt, Anton, and other disciples of Spener—the later leaders of the pietistic movement. This excited great irritation in the theological faculties of Wittenberg and Leipzig, which formally censured in 1695 as heretical no less than 264 propositions drawn from Spener's writings. Spener died at Berlin, February 5, 1705, leaving behind a reputation for piety, wisdom, and practical Christian energy which all the excesses of the later pietists have not obscured. Indeed Ritschl (*Gesch. des Pietismus*) maintains that he himself was not a Pietist, having no part in their characteristic quietist and separatist instincts.

His writings are numerous; the chief are *Pia Desideria* (1675), *Das geistliche Priesterthum* (1677), *Christliche Leichenpredigten* (13 vols. 1677), *Des thätigen Christenthums Nothwendigkeit* (1679), *Klagen über das verdorbene Christenthum* (1684), *Evangelische Glaubenslehre* (1688), and *Theologische Bedenken* (5 vols. 1700-2). See J. G. Walch, *Religions-streitigkeiten der Lutherischen Kirche* (5 vols. 1730-39); the Life by Hossbach (1828; 3d ed. 1861); the study by Thilo (1841); and the Life by Wildenhahn (1842-47; trans. by Wenzel, Phila. 1881).

Spennymoor, a town of Durham, 4 miles NE. of Bishop Auckland, with iron-foundries and coal-pits. Pop. (1851) 659; (1891) 6041.

Spenser, Edmund, one of the chief Elizabethan poets, was, as we learn from the *Prothalamion* (one of his minor poems), born in London, probably in East Smithfield near the Tower. From one of his *Amoretti* the date of his birth can with fair certainty be concluded to be 1552. As to his family, there are many indications that he was well connected, though his circumstances were poor. He speaks of himself as taking his name from 'an house of ancient fame,' and also of 'the noble familie, of which I meanest boast myself to be.' This noble family was that of the Spencers of Althorp. With the ladies of it he associates several of his poems. Thus in the dedication of *The Teares of the Muses* to the Lady Strange (in honour of whom in her old age it is interesting to notice Milton's *Arcades* was composed) he writes: 'The causes for which ye have thus deserved of me to be honoured (if honour it be at all) are both your particular bounties, and also some private bands of affinitie, which it hath pleased your Ladiship to acknowledge.' But in what degree he was connected with the Althorp Spencers has not yet been ascertained; it seems clear it was not a close relationship. What is fairly certain is that the poet's branch of the family belonged to the neighbourhood of Burnley in east Lancashire. Possibly his father came from Hurstwood, near Burnley. Gabriel Harvey, an intimate friend of Spenser's, speaks of Lancashire as Spenser's county; and there is much corroborative evidence of that statement to be drawn from the poet's own works as well as from the Burnley parish registers. But, however 'good' his family, Spenser's father was by no means well-to-do. It is conjectured that he was at one time 'a free journeyman' in the 'arte or mysterie of clothmakynge.' It is certain that his pecuniary means were so limited that in the education of his son, or sons, he was glad of assistance, and that even with assistance the poet went up to the university as a 'sizar.' So from the beginning Spenser did not enjoy worldly prosperity; from the beginning the saying of one of his admirers applies: 'Poorly, poor man, he lived; poorly, poor man, he died.' Of his mother nothing whatever is at present known, except that her Christian name was Elizabeth (*Amoretti*, lxxiv.).

His life appears to have been spent in London till his going up to Cambridge in 1569. The publication of 'The Spending of the Money of Robert Nowell of Reade Hall, Lancashire, brother of Dean Alexander Powell, 1568-1580,' has informed us that he was sent to the Merchant Taylors' School, then newly founded. He is first mentioned in those accounts as one of six 'poor scholars' of the Merchant Taylors' School, to whom the generous squire gave stuff for gowns. Thus Spenser would be a pupil of Mulcaster, though it was certainly not from him he learned to write English—unless indeed Mulcaster's theory was a great deal better than his practice, the style of his *Positions* being singularly affected and discommendable.

The Merchant Taylors' School was directly associated with Pembroke Hall (now College) at Cambridge; and in May 1569 Spenser duly proceeded from one to the other. Nowell's beneficence still attended him. Both at 'his going to Pembroke Hall' and twice at least while there he received presents. And these with the benefits of a sizarship must have reduced his university expenses to an amount which can have been no great burden to his father and family. As a scholar he does not seem to have specially distinguished himself at Cambridge. Perhaps, like Wordsworth two centuries later, he did not feel himself 'of that hour or that place.' There are traces of some friction between him and the authorities. But it is evident from his works that by the time he quitted the university in 1576 he had obtained a considerable acquaintance with both Latin and Greek literature. And he had made friends of note, who highly appreciated his genius; amongst them Gabriel Harvey and Edward Kirke.

And now what to do? He seems to have had no definite programme or prospect. He stayed for some months at least—perhaps for some two years—with his relations near Burnley, probably waiting on fortune. But this time was not all wasted; he had the experience of an unsuccessful love-suit; he pondered many questions of the day; and he perfected his metrical skill. The *Shepheards Calendar* was the result. And its publication in 1579 made an epoch in English literature. It was the first clear note of the great Elizabethan poetry. His contemporaries heard it with delight, and at once acknowledged its freshness and its charm.

Probably the year before its publication, or even in 1577—if, as words of his own seem certainly to prove, he was in Ireland that year—Spenser had gone south again, and had won the friendship of Sir Philip Sidney, to whom it was dedicated. How exactly he passed into the Sidney circle and became at home at Penshurst has not yet been made out. Possibly Gabriel Harvey was able to introduce him to the Earl of Leicester, who was Sir Philip's uncle. However this may be, Leicester and Sidney proved good patrons, and his friendship with the latter was one of the great events of his life (see *Astrophel*, *Ruins of Time*, &c.). And no doubt it was through Leicester's influence that in 1580 Spenser, long anxious for some employment or 'place,' was appointed private secretary to Arthur Lord Grey de Wilton, himself just appointed Lord Deputy of Ireland.

Ireland was thenceforward to be his home, little probably as such an issue of his secretaryship was expected, and eager as were his hopes and efforts to obtain some preferment in England. We cannot wonder that Spenser was ill content with his lot. The country was in rebellion when he arrived in it. The special mission of Lord Grey was to suppress the combined insurrection of the O'Neils in the north and the Fitzgeralds in the south, assisted by certain Spaniards who had lately fortified themselves at Smerwick in Kerry, a mission executed with a severity so merciless as to lead to his recall in 1582. Strange and fearful sights were presented to the young poet's eyes, of massacre, of desolation, of utter misery. The evil condition of things is vividly illustrated in Spenser's *View of the Present State of Ireland*—a work of ripe, however bitter, experience, and inspired by long and shrewd observation, written probably in the second decade of his Irish residence, and largely circulated in MS., though not printed till 1633. He strongly advocated the policy of strict repression and suppression. No wonder the natives loved Spenser as little as Spenser loved them. To this day, it is said, the peasants of Cork county remember him with detestation. However, it was in Ireland the unfortunate man was to pass his life, except for some two visits and a terror-stricken flight to England. Before his patron's recall he was already forming fresh connections with the country. In 1581 he was appointed Clerk of Degrees and Recognisances in the Irish Court of Chancery. In 1588 he became Clerk to the Council in Munster. Probably in this latter year he took up his abode at Kilcolman Castle near Doneraile, County Cork, though the grant of it and adjacent lands is dated October 26, 1591. He was certainly settled there in 1589, as we learn from himself in his *Colin Clout's Come Home Again*. His occupancy of a part of the forfeited estates of the Earl of Desmond must have stimulated the native hatred towards him; and it was probably already keen. Certainly he did much to further excite it by the rigour with which he pressed his rights or supposed rights. In one case at least it would seem that he pressed them too far. 'Edmond Spenser of Kilcolman, gentleman,' was ordered by the Lord Chancellor of Ireland to retire from 'three ploughlands, parcel of *Ballingerath*,' which he had 'entered,' disseising Lord Roche, Viscount Fermoy, thereof, and making 'great waste of the wood of the said land,' and converting 'a great deal of corn growing thereupon to his proper use, to the damage of the complainant of two hundred pounds sterling' (some £900 of our money).

But all this time, amidst all these enmities and horrors, Spenser was going on with this great poem, which, as we know from a letter of Gabriel Harvey's, had been begun before he crossed St George's Channel. The ninth canto of the second book is the first passage that pretty certainly points to his being in Ireland; and all the rest of it that was written was written in Ireland. In his sonnet to Lord Grey he describes his great work as

> Rude rymes the which a rustick Muse did weave
> In savadge soil far from Parnasso Mount,
> And roughly wrought in an unlearned loome.

In an interesting account given by his friend Lodovick Briskett of a party assembled at his cottage near Dublin in or about the year 1586, Spenser is reported as mentioning that he had already undertaken a work of ethical purpose 'which is in heroical verse under the title of a *Faerie Queene*,' and that he has 'already well entered into' it. By the year 1589 the first three books were finished, and in that year were shown to Sir Walter Raleigh, whose acquaintance Spenser had probably made some years before (they had certainly met at Smerwick in 1580, if not earlier), and who at this time was in some sort a neighbour, he too having a share (a large one) in the Desmond forfeiture and residing just then at Youghal. Of Raleigh's visit to Kilcolman in 1589 and its result in a journey to England and the English court Spenser gives a charming account in his *Colin Clout's Come Home Again*, written immediately after his return in 1591, though not published till 1595, and then slightly revised that it might be in its allusions more nearly 'up to date.' He and his poem were warmly welcomed. In 1590 the three books were published, and there arose a demand for other works of his, which was presently met by the publication of *Sundry Poems*, nine in number, some probably of early composition (as *Prosopopoia or Mother Hubberds Tale*, and in the main *Bellay's Visions* and *Petrarch's*), others written quite recently (as *The Ruins of Time* and *The Tears of the Muses*). But no place was found for him at the court or in London. Lord Leicester and Sir Philip Sidney were no longer on the scene to support him; and so once more to Ireland.

However, immense fame was his, if nothing of official or pecuniary advantage; and he devoted himself anew to his great work. Its course was interrupted by another great love-passion, of which he describes the various stages from despair to hope and to triumph in his *Amoretti* and his *Epithalamion*. The lady's Christian name was Elizabeth, as we learn from one of the courtship sonnets; her surname is very plausibly conjectured to have been Boyle. His happiness overflows even into the *Faerie Queene*. In book vi. canto x. his lady-love is introduced as a fourth Grace, and is described with much rapture. Finishing now the second three books, and perhaps proudly accompanied by his bride, he paid another visit to England. In 1596 was published the second and last instalment of the *Faerie Queene*, except a fragment consisting of two cantos and two stanzas. For a time he was the guest of Lord Essex; and under his roof, once that of Lord Leicester, he composed what is probably his last complete poem, *The Prothalamion, or a Spousal Verse.* Even in this song of congratulation and joy his anxiety and distress find expression. He speaks of himself as one

> Whom sullen care,
> Through discontent of my long fruitless stay
> In Prince's Court, and expectation vain
> Of idle hopes which still do fly away
> Like empty shadows, did afflict my brain

(his emotion overpowering his grammar), and of his 'friendless case.' But again his suit obtained no success; and again he turned his face to the country, not of his choice, but of his necessity.

Meanwhile in that unhappy island a fresh storm had been gathering, and in 1598 burst furiously on the head of the unpopular occupant of Kilcolman. One of the first exploits of the new insurrection (that under Hugh O'Neil) was to fire Spenser's castle; and he and his had to flee for their lives. About the close of 1598 or the beginning of 1599 he reached London homeless, destitute, exhausted. On January the 13th (not the 16th, as is usually said; see John Chamberlain to Sir Dudley Carlton, January 17. 1599) he died at a tavern in King Street, Westminster, certainly in distressed circumstances, if not, as Ben Jonson stated to Drummond, and we would fain not believe, 'for lack of bread.' At least in his last resting-place he was happy; he was laid by Chaucer—by him who taught him his songs, as he was proud to say—in the south transept of Westminster Abbey. And, if admiration and fame were or are any compensation for his adverse fortunes, such compensation was and is his in no slight measure. His wealth of language, his fine sense of melody, his abundance of fancy, his ardent patriotism, his profound sympathy with all things lovely and of good report gave him at once and have retained for him a foremost position in English literature. It is his special and his supreme distinction to be known, and with good reason, as the 'Poet's Poet.'

See editions by Todd (8 vols. 1805) and A. B Grosart (10 vols. 1882-84); of the Poems, the Aldine edition, with Life by Collier, and the Globe edition, with Memoir by the present writer; Dean Church's *Spenser* and J. A. Symonds' *Sidney* in 'English Men of Letters;' Craik's *Spenser and his Poetry* (3 vols. 1845); Sir John Pope Hennessy's *Sir Walter Raleigh in Ireland* (1883); Dean Kitchin's *Faerie Queene* (books i. and ii.).—The 'Spenser Society,' founded 1867-68, has printed works of Heywood, Taylor the Water-poet, Wither, Drayton, &c.

Spermaceti is a waxy matter obtained mixed with oil from the head of the sperm-whale, *Physeter macrocephalus.* The mass obtained from an ordinary sized whale would fill twelve barrels. It is purified by draining off the oil and repeatedly washing with hot water and weak boiling potash-lye. It is in white, pearly, semi-transparent masses, somewhat unctuous to the touch, lighter than water, and melting a little above 100° (38° C.). It is insoluble in water, but soluble in ether, chloroform, &c. Medicinally it is no longer given internally, but it is an ingredient of many ointments, to which it gives a crystalline appearance. Chemically it is almost pure cetyl palmitate, but contains small quantities of other fats. See WHALE.

Spermatozoa, the male reproductive cells of animals, the physiological complements of the egg-cells or ova. See EMBRYOLOGY, REPRODUCTION.

Sperrylite, the name given to an arsenide of platinum ($PtAs_2$) discovered in 1888 in the province of Ontario, Canada.

Speusippus (B.C. 394–336?), an Athenian philosopher, who, after the death of his uncle Plato, became head of the Platonic school or Older Academy. Of his philosophical works, in which he taught a doctrine differing but little from Plato's, nothing is left but titles and fragments.

Spey, a river of Scotland, rising at an altitude of 1500 feet above sea-level and running 107 miles north-eastward through or along the boundary of Inverness, Elgin, and Banff shires, until it falls into the Moray Firth at Kingston between Lossiemouth and Portknockie. The Dulnain and Avon are its principal tributaries. The salmon-fisheries, belonging to the Duke of Richmond, at its mouth, above which comparatively few fish penetrate, have a yearly value of from £8000 to £10,000; else the Spey is almost without value, nor can it generally be called a picturesque stream. It has the swiftest current of all the large rivers in Britain, and is subject to sudden and violent freshets, resulting at times in disastrous inundations. See Sir Thomas Dick Lauder's *Moray Floods* (1830); and A. E. Knox, *Autumns on the Spey* (1882).

Speyer. See SPIRES.

Spezia, the principal naval port of Italy, stands near the head of a deep and commodious bay on the west side of the peninsula, 56 miles SE. of Genoa by rail. It was Napoleon I. who first recognised the suitability of this bay for the purposes to which the Italians, instigated thereto by Cavour, have now put it. An artificial breakwater (built in 1860), 2400 feet long, covers the entrance; whilst formidable batteries of the heaviest artillery (supplemented by torpedo appliances) bristle on the hills that overlook the bay and on the island of Palmeria that guards its entrance. Here the Italians have constructed the great national arsenal, and build their large warships, and have their ship-repairing yards and docks, and their naval victualling yards, storehouses, and so forth. Some of these, however, are at San Bartolomeo, on the opposite shore of the bay. There are also in the town large barracks, a military hospital, schools of navigation, an iron-foundry, and manufactures of cables, sail-cloth, and white-lead. The adjacent country produces excellent olive-oil. The beauty of the bay and the lovely climate cause Spezia to be much frequented as a seaside resort. It was on the shores of this bay that Shelley spent the last few months of his life, while at the town of Spezia Charles Lever lived and wrote for some years. Pop. (1861) 6105; (1881) 19,864.

Spezzia (or *Spetsai;* ancient *Pityussa*), a Greek island at the entrance to the Gulf of Nauplia. Area, 6½ sq. m.; pop. 6899, engaged chiefly in commercial pursuits. The town of Spezzia has a good harbour and 6494 inhabitants.

Sphæro-siderite, the name given to impure or earthy and frequently concretionary varieties of carbonate of iron.

Sphagnum, a genus of Mosses, whose spore-case is an urn closed by a deciduous lid, and its brim toothless, the calyptra irregularly torn. Several species are natives of Britain, and are common in bogs, from which they derive their popular name, *Bog Moss.* They are remarkable for the whitish colour of their leaves. They are very elegant plants. They often grow in considerable masses, absorbing water like a sponge, but becoming friable when dry. They contribute much to the formation of peat. Gardeners employ them in preference to other mosses for covering the roots of plants and keeping them moist, as they have in a high degree the property of absorbing moisture from the atmosphere. They have been used as food in barbarous countries, but are very slightly nutritive. The cells of the leaves are remarkable for their spiral structure, and for large pores in their sides. See MOSSES; and Braithwaite, *The Sphagnaceæ* (1880).

Sphene. See TITANITE.

Sphenodon, or HATTERIA, a remarkable reptile, often called the New Zealand Lizard, but deserving, on account of its peculiarities, to be ranked as the only living representative of a distinct order—Rhynchocephalia—which in Permian and Triassic times included several genera. Now, however, there is only one species—*Sphenodon,* or perhaps better *Hatteria, punctata*—the Tuatara of the Maoris. It was formerly abundant along the coasts of New Zealand, but is now restricted to a few small islands in the Bay of Plenty, both the Maoris and the hogs being blamed for its rapidly increasing rarity. In all likelihood it will soon be exterminated, and one of the most interesting of 'living fossils' will be lost.

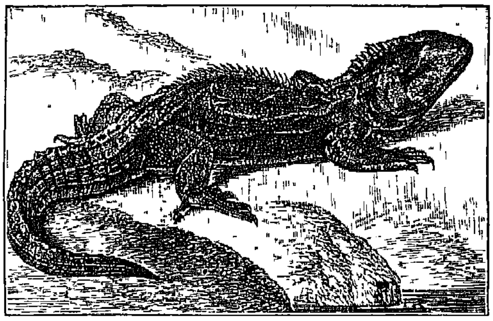

Fig. 1.—Sphenodon (*Hatteria punctata*).

In appearance the Hatteria is like an Iguana; on the upper surface the general colour is 'dull olive-green spotted with yellow,' on the under surface whitish; the tail is compressed from side to side and dorsally crested, brittle and replaceable as in many of the genuine lizards. The maximum length of the animal seems to be about two feet, but smaller forms are commoner. Nocturnal in its habits, the Hatteria lives in holes among the rocks or in small burrows, and feeds on small animals.

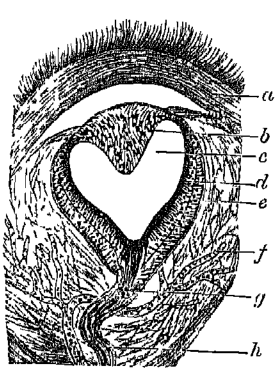

Fig. 2.—Section of Pineal Eye of Hatteria (after Baldwin Spencer):
a, a connective-tissue capsule beneath the skin; *b*, the lens; *c*, the cavity of the eye; *d*, *e*, layers of the retina; *f*, blood-vessels; *g*, *h*, stalk.

But the chief peculiarities of this old-fashioned reptile are internal, and cannot be stated except in technical language. The vertebræ are biconcave like those of most fishes, as is also the case in geckos among lizards and in many extinct reptiles. Some of the ribs bear uncinate processes as in birds and crocodiles. As in crocodiles there are 'abdominal ribs,' or ossifications in the fibrous tissue beneath the skin of the abdomen. The skull, unlike that of any lizard, has an ossified quadrato-jugal, and therefore a complete infra-temporal arcade; the quadrate is immovably united to pterygoid, squamosal, and quadrato-jugal; the pterygoids meet the vomer and separate the palatines. There are teeth on the palatine in a single longitudinal row, parallel with those on maxilla and mandible, and the three sets seem to wear one another away; there is also a single tooth on each side of a sort of beak formed from the premaxillæ.

It was in Hatteria first that Baldwin Spencer discovered what seems to be the secret of the pineal body. This structure occurs in all Vertebrates, except the very lowest, at the end of an upgrowth from the 'tween brain or optic thalami. Its import remained for long an enigma. But in Hatteria the pineal body reaches the skin on the top of the head, and retains distinct traces of an eye-like structure—for instance a complex retina. As the same vestigial hint of eye structure has since been seen in several lizards, many naturalists are confident that the pineal body should be called a pineal or parietal eye, and regarded as a persistent vestige of a median, unpaired, upward-looking sense-organ. See PINEAL GLAND.

Near the living Hatteria the Permian Palæohatteria, the Triassic Hyperodapedon, and some other important extinct types must be ranked. Nearly allied too is the remarkable Proterosaurus from the Permian. There is no doubt that the order Rhynchocephalia once included several generalised types, of which Hatteria now alone remains. It is much to be desired that the development of this animal be studied before it also disappears.

Sphenoid Bone. See SKULL.

Sphere, a surface of which every point is equally distant from a definite point known as the centre. It may be described by the rotation of a semicircle (or circle) about its diameter. From every aspect a sphere has the same appearance. Every plane section is a circle—a *great circle* if the cutting plane contains the centre of the sphere, a *small circle* in all other cases. The shortest line that can be drawn on the surface so as to join any two points must be an arc of the great circle passing through these two points. If r is the radius of the sphere its volume is $\frac{4}{3}\pi r^3$ and its surface is $4\pi r^2$. These are intimately related to the volume and curved portion of the surface of the circumscribing cylinder, whose height is equal to the diameter of the sphere. The volumes are as two to three, and the surface areas, so defined, are equal.

Spheroid is a species of Ellipsoid (q.v.), and is represented by the same equation. If an ellipse be made to revolve round one of its axes, the curved outline of the ellipse describes the spheroid. Should the major or longer axis be the axis of revolution the spheroid is said to be *prolate*, but if the minor or shorter axis, *oblate*. The Earth (q.v.) is very approximately an oblate spheroid.

Spherometer is an instrument for measuring the sphericity of portions of spherical surfaces—for example, lenses. It rests on three pointed legs, whose points form an equilateral triangle. Midway between these is a fourth leg, which can be screwed up or down as desired through a distance measured by the number of turns given to it. After the spherometer is adjusted on any spherical surface till the four legs are all in contact with the surface it is lifted on to a plane surface and the middle leg screwed up or down until the four legs all lie on the plane. Thus we measure the height of the segment whose base is the circle passing through the equilateral triangle mentioned above, and can by a simple calculation find the radius of the spherical surface. The instrument may also be applied to measure the thicknesses of plates small enough to be pushed within the legs.

Spherical Aberration. See LENSES, and MIRROR.

Spheroidal Condition of liquids is the name usually given to a series of very singular phenomena discovered by Leidenfrost (1715-94), but first carefully investigated by Boutigny (1858). Indeed one, at least, of those phenomena has been popularly known for a very long time, being the foundation of the rough practical method of determining whether or not a flat-iron is so hot as to be likely to singe the linen to which it is to be applied. The test consists simply in letting a drop of water fall upon the iron. The drop will either glance off the surface without wetting it or will spread over the surface and evaporate, according as the iron is or is not too hot.

The common experimental method of exhibiting the spheroidal condition is easily performed thus: A metallic disc, slightly concave, like a watch-glass, is heated by a lamp, and water is cautiously dropped on it from a pipette. If this be done before the disc is sufficiently heated the water boils almost explosively, and is dispersed at once in vapour. But when the disc is hot enough the water remains suspended, as shown in the cut, *above* the surface; and the drop, when small, takes nearly the form of an oblate spheroid. The most curious fact connected with the experiment is that the water does *not* boil. In fact it evaporates so freely that the heat carried off from it, as latent heat, by the vapour which is constantly formed keeps its temperature somewhere about 206° F only. *Boiling* water, dropped on a red-hot plate of metal, instantly assumes the spheroidal state, and is *cooled* six degrees below boiling. Other liquids, and even some bodies which are solid at ordinary temperatures, can be easily brought into the spheroidal state—the lowest requisite temperature of the disc being dependent on the boiling-point of the substance. A good example of a solid entering this state is furnished by dropping crystals of iodine on a hot platinum disc. It is not necessary that a metal plate be used. For example, a watch-glass will suffice for the experiment; but *hot* water must be dropped on it, else the glass will crack. Also we may obtain ether, and even water, in the spheroidal state over the surface of hot oil. The explanation of the phenomenon is to be sought for in the existence of a cushion of vapour between the hot plate and the drop. The high temperature of the plate causes a rapid evaporation of the lower surface of the drop. The vapour particles coming into contact with the hot plate are raised in temperature, that is, have their kinetic energy increased. They tend to rebound with increased energy back upon the drop, whose weight they are thus able to support.

An interesting illustration of the spheroidal state is the fact that the hand may be dipped for a short time with impunity into melted lead, and even into melted copper. The vapour instantly raised from the moisture of the skin prevents, so long as that moisture lasts, more than an endurable amount of radiant heat from reaching the hand, and also prevents direct contact.

Spherulitic Structure. See PETROGRAPHY.

Sphex, a genus of hymenopterous insects of the family Sphegidæ, closely allied to the true Wasps (Vespidæ). The Sphex wasps are solitary in habit, and there are no workers as in the social forms. The female hollows out, at the end of a long passage, three or four chambers, in each of which she deposits an egg and a store of food for the larva she will never see. The food consists of grasshoppers or other insects, and Fabre gives a minute account of the way in which the Sphex attacks her victim, and, after a long and violent struggle, throws it on its back and stings it in the neck and between the thorax and abdomen, each time piercing a ganglion. The insect, completely paralysed, but alive, and therefore not liable to putrefaction, is then dragged to the mouth of the nest, where it is relinquished for a short time, while the wasp enters alone to see that all is right. So automatic is this habit of reconnoitring that if the grasshopper be removed to a little distance the wasp drags it back to the same spot and again enters alone. This was tested by the observer forty times in succession, and each time the wasp paid her preliminary visit of inspection. But, in proof that she is not wholly the slave of habit, it should be noted that when Fabre substituted a fresh grasshopper for the paralysed one she at once perceived the difference, and proceeded to attack and sting her recalcitrant victim. Four paralysed insects are placed in each chamber, which is sealed up as it is finished. When all are full the mouth of the passage is also closed, and the nest is abandoned. See WASP.

Sphincter Muscles (Gr. *sphinktēr*, 'that which binds tight') surround an opening or canal which, by their action, they are able to close or diminish in size. They are found round the mouth, the opening between the eyelids, round the pupil of the eye, the pylorus of the stomach, the outlet of the urinary bladder, and the anus. It is to the presence of these muscles that the higher animals owe the power of retaining for a considerable period the excrementitious matters collected in the bladder and rectum, and of discharging them at intervals, the sphincter muscles being, like those engaged in the process of respiration, mainly, but not entirely, under the control of the will.

Sphinx, a Greek word signifying the 'strangler,' applied to certain symbolical forms of Egyptian origin, having the body of a lion, a human or an animal head, and two wings. Various other combinations of animal forms have been called by this name, although they are rather griffins or chimæras. Human headed sphinxes have been called androsphinxes; that with the head of a ram, a criosphinx; and that with a hawk's head, a hieracosphinx. The form when complete had the wings added at the sides; but these are of a later period, and seem to have originated with the Babylonians or Assyrians. In the Egyptian hieroglyphics the wingless Sphinx bears the name of *Neb*, or Lord, and *Akar*, or Intelligence, corresponding to the account of Clement that this emblematic figure depicted intellect and force. Others see in it the idea of resurrection, symbolised by the triumph of the dawn over the darkness of night. The idea that it allegorised the overflow of the Nile when the sun was in the constellations Leo and Virgo appears to be unfounded. In Egypt the Sphinx also occurs as the symbolical form of the monarch considered as a conqueror, the head of the reigning king being placed upon a lion's body, the face bearded, and the usual head-dress. Thus used, the Sphinx was generally male; but in the case of female rulers the figure has a female head and the body of a lioness.

The most remarkable Sphinx is the Great Sphinx at Gizeh (Gîza), a colossal form hewn out of the natural rock, and lying about a quarter of a mile south-east of the Great Pyramid. It is sculptured out of a spur of the rock itself, to which masonry has been added in certain places to complete the shape, and it measures 172 feet 6 inches long by 56 feet high (Vyse, *Pyramids*, iii. 107). Immediately in front of the breast Caviglia found in 1816 a small naos or chapel, formed of three hieroglyphic tablets, dedicated by Thothmes III. and Rameses

II. to the Sphinx, whom they adore under the name of Haremkhu, or Harmachis, as the Greek inscriptions found at the same place call it—i.e. the Sun on the Horizon. These tablets formed three walls of the chapel; the fourth, in front, had a door in the centre and two couchant lions over it. A small lion was found on the pavement, and an altar between its fore-paws, apparently for sacrifices offered to it in the time of the Romans. Before the altar was a paved causeway or dromos, leading to a walled staircase of thirty steps, repaired in the reign of M. Aurelius and L. Verus on the 10th May 166 A.D. In the reigns of Severus and his sons, 199-200 A.D., another dromos, in the same line as the first, and a diverging staircase were constructed, while some additions had been made to the parts between the two staircases in the reign of Nero. Votive inscriptions of the Roman period, some as late as the 3d century, were discovered in the walls and constructions; and on the second digit of the left claw of the Sphinx an inscription in pentameter Greek verses, by one Arrian, probably of the time of Severus, was discovered. In addition to these walls of unburnt brick, galleries and shafts were found in the rear of the Sphinx extending northwards. The excavations of M. Mariette in 1852 threw further light on the Sphinx, discovering that it was surrounded by a peribolos or outer wall; and showing that the head only was sculptured; that the sand which had accumulated round it was brought by the hands of man and was not an encroachment of the desert; and that the masonry of the belly was supported by a kind of abutment. To the south of the Sphinx Mariette found a dromos which led to a temple of the time of the fourth dynasty, built of huge blocks of alabaster and red granite. In the midst of the great chamber of this temple were found seven diorite statues, five mutilated and two entire, of the monarch Chafra or Chephren, which are fine examples of the oldest Egyptian sculpture. While the dignity and grandeur of the Great Sphinx have often attracted the admiration of travellers (see SCULPTURE, p. 264), its age has always remained a subject of doubt; but these later discoveries prove it to have been a monument of at least the age of the 4th dynasty, or contemporary with the pyramids, and Maspero regards it as anterior even to Menes.

Great Sphinx at Gizeh

Besides the Great Sphinx, avenues of Sphinxes have been discovered at Sakkara, forming an approach to the Serapeum of Memphis and elsewhere. Sphinxes of the time of the Shepherd dynasty have been found at Tanis, and another of the same age is in the Louvre; while a granite Sphinx, found behind the 'vocal Memnon,' and inscribed with the name of Amenophis III., is at St Petersburg. An avenue of criosphinxes, each about 17 feet long, is still seen at Karnak, and belongs to the time of Horus, one of the last monarchs of the 18th dynasty. Various small Sphinxes are in the different collections of Europe, but seldom are of any very great antiquity.

The Theban Sphinx of Greek legend, whose myth first appears in Hesiod (*Theog.* 326), is described as having a lion's body, female head, bird's wings, and serpent's tail, ideas probably derived from Phœnician sources. She was said to be the issue of Orthros, the two headed dog of Geryon, by Chimæra, or of Typhon and Echidna, and was sent from Ethiopia to Thebes by Hera to punish the transgression of Laius, or, according to other accounts, by Dionysus or Ares (see ŒDIPUS). The Sphinx was a favourite subject of ancient art, and appears in reliefs, on coins of Chios and other towns, and often as a decoration of arms and furniture. In Assyria and Babylonia representations of Sphinxes have been found, and the same are not uncommon on Phœnician works of art.

Sphinx. See HAWK-MOTH.

Sphygmograph, an instrument for indicating changes of tension in the blood in an artery; practically a pulse-recorder. It was invented by Vierordt, and perfected in 1863 by M. E. J. Marey of Paris. When the instrument is applied to an artery a moving point traces a record on a band of paper moved by clockwork. A sphygmophone is a sphygmograph combined with a microphone. A sphygmoscope renders the pulsations visible. See works by J. B. Sanderson (1867), Dudgeon (1882), Bramwell (1883), and Keyt (1887).

Spice Islands. See MOLUCCAS.

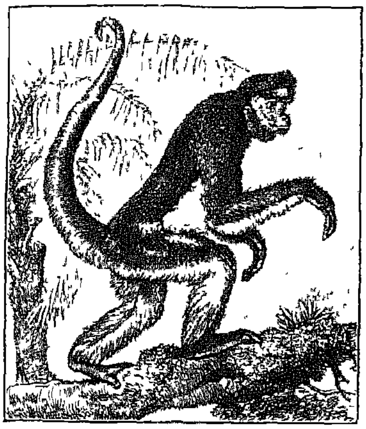
Spices (Lat. *species*, 'kinds;' in later Latin, kinds of goods, or produce in general; and then the most highly prized kind of goods, the aromatic productions of the East), aromatic and pungent vegetable substances used as condiments and for flavouring food. They are almost exclusively the productions of tropical countries. In ancient times and throughout the middle ages all the spices known in Europe were brought from the East; and Arabia was regarded as the land of spices, but rather because they came through it or were brought by its merchants than because they were produced in it, for they were really derived from the farther east. They owe their aroma and pungency chiefly to essential oils which they contain. They are yielded by different parts of plants; some, as pepper, cayenne pepper, pimento, nutmeg, mace, and vanilla, being the fruit or particular parts of the fruit; whilst some, as ginger, are the root stock; and others, as cinnamon and cassia, are the bark. Tropical America produces some of the spices, being the native region of cayenne pepper, pimento, and vanilla; but the greater number are from the East.

Spicheren, or SPEICHERN, a village on the frontiers of Prussia and Lorraine, 2 miles S. of Saarbrück. Here on 6th August 1870 was fought a bloody battle between the French and Germans, in which the former were defeated. See FRANCE, Vol. IV. p. 782; and the work on the battle by Major Henderson (1892).

Spider-crab. See CRAB.

Spider-fly (*Ornithomyia*), a genus of dipterous insects closely allied to the Forest-fly, but parasitic on birds, not on quadrupeds. Thus, *O. avicularia* frequently infests the common fowl, the blackcock, and other birds in Britain. It is greenish yellow, with smoke-coloured wings.

Spider-monkey, a name given to an American genus of monkeys, Ateles. These monkeys have no thumb, or it is rudimentary. They occur only in South America, Mexico, and Central America. The popular name has been given to them on account of their long, slender limbs. Like other New-World monkeys (Platyrrhini), they have a prehensile tail, and are naturally purely arboreal in habit. Although denizens of the tropical forests of the New World, they can, like the tropical apes of the Old World, endure a very considerable amount of cold. One species, *A. vellerosus*, lives in large companies in forests at a height of 7000 feet in Mexico. The Coaita is the *A. paniscus*. About fourteen species of the genus are known.



Spider-monkey (*Ateles Bartlettii*).

Spiders (*Araneidæ*) form an order within the heterogeneous class Arachnida. The name, which seems to be a corruption of *spinther*, refers to the well-known spinning powers which these animals so cleverly exercise. They are found almost everywhere upon the earth, especially in warm countries, and are of much importance in checking the multiplication of insects. A few tropical forms, notably the bird-catching spiders, exceed two inches in length of body, but the majority measure only some fraction of an inch.

Structure and Functions.—The body is divided into two distinct parts—an unsegmented cephalothorax, bearing six pairs of appendages, and a soft unsegmented abdomen, at the end of which are the spinnerets. On the skin there are hairs of various kinds, some being specialised as sensitive structures. The colours, which are often very brilliant, are due in part to pigments occurring in the tissues, or diffused on the skin, or concentrated in special chromatophores, in part also to the way in which the light is reflected from the hairs and skin. They vary with age and sex, with food and environment, and, as we shall see, are often of importance in courtship and in protective adaptations. Soon after the young spider is hatched it casts its cuticle, and this moulting is repeated at intervals until the full size is reached. It is probable that the Attidæ moult from seven to eleven times before reaching maturity. As this moulting proceeds, the colour, which in young spiders is generally bright yellow or green, whitish or livid, gradually becomes in tints and markings that which is characteristic of the species.

There are six pairs of appendages: (1) the clawed cheliceræ or falces, of which the last joint works against the second last and contains a poison gland; (2) the leg-like pedipalps, the terminal joint of which is modified in the male for copulatory purposes; (3–6) four pairs of walking-legs, of which the foremost pair are much used as feelers. The embryo has four pairs of abdominal legs which abort. Near the anus are situated two, three, or four pairs of closely approximated spinnerets, and on each of these there are numerous 'spinning-spools,' out of which oozes the viscid fluid which hardens into the silken thread. A figure is given of the foot of the hindmost leg in the Garden Spider, showing the claws and spines, which are of use in drawing out the silken secretion. Among other external characters are the simple eyes, of which a variable number, most frequently eight, occur on the head; the openings or stigmata of the respiratory sacs or tubes; the opening of the reproductive ducts between the anterior stigmata; and (in the female) the adjacent but separate aperture or apertures of the receptacula seminis.

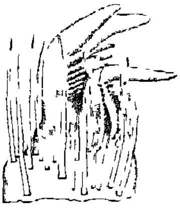


Fig 1.—Foot of Garden Spider.

The nervous system conforms to the usual Arthropod type, consisting of a dorsal brain, a ring round the gullet, and a ventral nerve-cord; but the ventral ganglia are concentrated in a single ganglionic mass in the thorax, giving off nerves to the limbs and other parts.

As regards the senses of spiders, it seems that few have much power of precise vision. Some discern rapid movements of objects, but seem unable to see their cocoon though it be but a few inches off. The hunting Saltigrades, however, have been observed to stalk prey from a distance of 10 inches, but that this is regarded as exceptional shows how limited the ordinary power of vision is believed to be. In many cases it has been experimentally proved that spiders exhibit an apparent preference (perhaps dependent on sexual associations) for certain colours, and it is certain that the males of some kinds (e.g. Attidæ) display their bright colours before their desired mates. The limited nature of visual power is in great part compensated for by the exquisite delicacy of the sense of touch, for the lurking spinner feels rather than sees the insect tangled in its snare or web. Vibrations such as those caused by the whizzing of insects' wings or by a tuning-fork are propagated along the taut lines of the web and interpreted by the spider. According to some observers, the courtship is sometimes conducted in this telephonic fashion. This tactile sensitiveness seems to be in great part diffused over the body, but the hairs towards the ends of the legs are specially sensitive. We know little with regard to the sense of hearing in spiders. That some males, e.g. of Theridium and Mygale, are able to produce a stridulating noise, suggests that their mates can hear, but the evidence is not conclusive. Nor are the numerous accounts of spiders which descend chandeliers and the like to listen to music, for spiders often do this when there is no music, and are especially likely to do this of an evening, and it is difficult to abstract the influence of vibrations other than those of sound-waves. Many, however, believe that spiders really hear, and it may be that careful experiments will prove that what are described as 'auditory hairs' on the palps and legs are really such. The sense of smell seems to be slight, though marked for certain strongly-scented substances, and there is a sensory structure, perhaps olfactory or gustatory, on the basal joint of the pedipalps.

All spiders are predaceous and feed on insects, which they entangle in their snares and webs, or stalk, or catch after patient lurking. In most cases they kill their prey with their poisonous falces. The mouth is small, and behind the gullet there is a powerful suctorial region which acts as a suction-pump. From the mid-gut five paired outgrowths extend into the bases of the pedipalps and legs. There are also large tubular digestive outgrowths, and two excretory Malpighian tubes grow out from the hind gut. The heart lies dorsally in the abdomen, and has three chambers with three pairs of valved openings. In one set (Tetrapneumones, e.g. the bird-catching Mygale; see BIRD-CATCHING SPIDER) there are four pulmonary sacs like those of the scorpion; in the great majority (Dipneumones) there are two pulmonary sacs and two main tracheal tubes.

The sexes are separate except in a few casual hermaphrodites, and the males are often fewer in number, always smaller in size, and usually more brightly coloured than the females. In most cases, as we shall afterwards see, the courtship is elaborate, and is often attended with considerable danger to the males. The fertilised egg segments peripherally, like that of insects, around a central core of yolk. A cocoon is usually formed around the eggs, and this is hidden or carried about by the female, who exhibits much maternal solicitude.

The fertility of spiders varies in different species within wide limits. Thus, as Mrs Peckham notes, one species may lay 800 or 1000 eggs, while another, equally common, lays only fifty. In the family Epeiridæ *Argiope cophinaria* lays 500 to 2200 eggs, while *Tetragnatha laboriosa* lays only 34; in the family Attidæ *Phidippus morsitans* lays about 180 eggs, while *Synageles picata* lays only three. While the rate of multiplication is immediately dependent on the constitution of the different species, it also bears some relation to the rate of mortality, or, what comes almost to the same thing, to the efficiency of the protective adaptations by which spiders are saved from their enemies. Those with a low birth-rate are usually protected very efficiently, and have consequently a low rate of mortality.

In many cases female spiders are savage and quarrelsome, fighting with one another, and frequently destroying the smaller males when these offer them amatory attentions. 'Ridiculously small and weak in build, the males of many species can only conduct the rites of marriage with their enormous and voracious brides by a process of active manœuvring, which, if unsuccessful, is certain to cost them their lives.' In a great number of cases, e.g. in at least two-fifths of all the species of Attidæ, the males are more brilliantly coloured than the females, and that this is in part related to sexual selection is rendered almost certain by the observations of Professor and Mrs Peckham, who often worked four or five hours a day for a week in getting a fair idea of the habits of a single species. They describe among many species of Attidæ the manner of the wooing, the cautious circling dances of the ardent males, the strange attitudes by which they display their charms of colour, the occasional wooing by vibrations of the web-lines, the captious irritability of the females, who often bring the courtship to a tragic end, the quarrelsomeness of rival males in presence of the females. 'The males vie with each other in making an elaborate display, not only of their grace and agility but also of their beauty, before the females, who, after attentively watching the dances and tournaments which have been executed for their gratification, select for their mates the males which they find most pleasing' (see SEXUAL SELECTION).

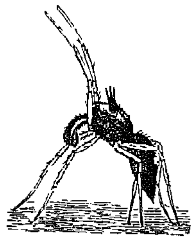

Fig. 2.—*Astia vittata*, male 'displaying his charms.'
(After G. W. and E. G. Peckham.)

Spinning-work.—On each of the spinnerets—of which in the majority there are six—there are numerous, usually sixty to seventy, 'spinning-spools,' out of which there flows a viscid secretion formed in the numerous internal glands. The resultant thread into which the secretion hardens, though of a delicacy hardly rivalled except by quartz fibres, is from the nature of its origin a complex structure. Its texture is not always the same; it may be covered with minute adhesive beads, or be stronger and unbeaded, or very light and filmy as in gossamer. In some spiders there is a special chitinous plate—called the cribellum—lying in front of the spinnerets and perforated by the ducts of numerous glands. 'Its presence is correlated with that of the calamistrum, a single or double row of long wavy hairs on the dorsal aspect of the second last tarsal joint of the fourth pair of walking-legs. One of the calamistra is rapidly vibrated over the cribellum, and draws out the secretion from the glands in the form of threads, used to strengthen the web, to assist in forming the cocoon for the eggs, and sometimes perhaps in making a domicile.'

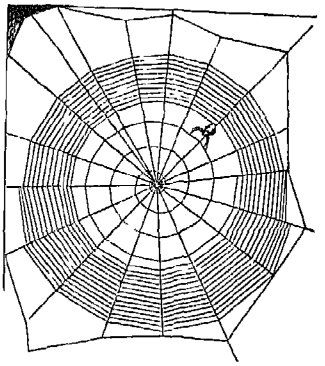

Fig. 3.—Garden Spider spinning her web.
(From 'Riverside' *Natural History*.)

The webs of spiders vary as much as do the nests of birds, but as a single example of their making we may take that of the Common Garden Orb-weaver (*Epeira diadema*). The spinner first lays down a number of firm foundation-lines, which may be disposed 'by hand' if the situation admits of this, but are more frequently blown fortuitously by air-currents. Having secured a number of these foundation-lines enclosing the area for the web, the spider forms the radii which intersect in the centre. This done, she begins from the centre and stepping outwards in a wide spiral lays down the spiral scaffolding. Finally, beginning at the circumference and working inwards, the spider lays down the delicate viscid spirals on which the efficiency of the web depends. The primary spirals simply form a scaffolding, and are undone, in fact eaten up, as they are replaced. But the web of the garden spider is a comparatively simple case; we have to distinguish 'orb-webs,' 'ribboned orbs,' 'composite snares and sectional orbs,' 'horizontal snares and domed orbs,' 'unbeaded orbs and spring snares,' and so on, as Dr McCook, in his incomparable work on American spiders, has pointed out.

No structures made by animals—not even the nests of birds, the homes of bees, the hills of the Termites—are more marvellous than the webs and snares of spiders. The framework is so delicate yet so effectively firm, so clever in its construction, so sensitive, we may almost say, in its mechanism, that we must rank it highest among works of instinctive art. Instinctive, for each species of weaver has its characteristic web, and there is no reason to suppose that the art of making this is the result of education. Yet the mode of construction is not rigidly fixed, but varies a little according to the site, according to the wind, and even, it is said, in relation to the abundance of insects in the neighbourhood. We see the strength of the web when it remains unbroken in the wind, and when it is laden with drops of dew, but sometimes it is much stronger than such sights suggest. Mosely tells how Willemoes Suhm on the *Challenger* expedition found a Glossy Starling (*Calornis metallica*) hopelessly entangled in a spider's web, and other naturalists relate the same of humming-birds and other small creatures. Thus a snake, nine inches long, has been found hanging in a web; and Dr McCook, whose carefulness as an observer is worthy of all praise, relates how a young living mouse was in some manner securely entangled in the snare of a spider, how the spinner, by means of silken threads two or three feet long, hoisted the mouse up four inches, and how the mouse after living for ten hours at length succumbed. A spider three-quarters of an inch in length has been seen to land a fish about three inches in length, but perhaps the raising of a mouse in a web is more wonderful. Mr Wallace and other exploring naturalists also tell of spider-webs strong enough to be a serious obstacle to travellers in the woods, and in other reports fancy has magnified this strength tenfold. As to the intelligence involved in modifying the web in various conditions it is not easy to form an accurate estimate. On a long hedge we may see scores of webs disposed so as best to stand the stress of the prevailing wind, but we must remember that the foundation-lines of the web are in most cases wind-blown. Often in the geometric webs there are interesting irregularities which show that equal precision is not always attained. On the other hand fractured snares are sometimes mended by skilfully disposed trusses. Many observers have described cases where small stones were found hung from the web, as if to weight them against the force of the wind. But McCook maintains, and we would agree with him, that it is most likely that these stones have been raised from off the ground by the shrinkage of the web, and that the alleged advantage—which, if foreseen, involves a complex inference—is simply accidental.

The threads which the spiders spin are used not only in fashioning webs and snares, but in many different ways. Behind them, as they move where a footing is insecure, there trails a drag-line, perhaps the rudiment of all their weaving, and this is of special use when they drop from a height. Jonathan Edwards long ago (1716) observed that spiders in order to cross an unbridged gap will form a sort of swinging basket, and he also noticed their exceedingly strange habit of ballooning. Raising themselves on tiptoe and with upturned abdomen on some point of vantage, they allow long threads of gossamer to float out in the air until these acquire sufficient momentum to carry the spider aloft. In this way they have been known to cross considerable sheets of water. 'To this mode of diversion young spiders of several families are very much addicted, especially in the fine days of autumn. Sometimes the flying threads are excessively numerous, and on their descent cover everything: they are particularly striking on hedges, and constitute, at all events, one of the causes of the phenomenon well known in the country as gossamer.' And again, the threads may help to form the cocoon for the eggs, or may be used to bind leaf to leaf and form a well-hidden nest.

Enemies and Protective Adaptations.—While spiders are the fatal enemies of many insects, they are in turn frequent victims. 'To feed the hungry maw of a stronger, more skilful, or more fortunate fellow Araneid; to be paralysed and entombed within a clay sarcophagus by a mother wasp, and serve as food for a growing waspling worm (see SPHEX); to be snapped up as a delicate titbit by birds, toads, and other creatures—these are some of the ways in which the spider meets its doom.' Among birds the chief enemies of spiders are the humming-birds, among insects the wasps. The ichneumon flies often lay their eggs—with destructive results—in the cocoons of spiders. Small monkeys prey upon spiders a good deal, and so do some insectivorous mammals. Between different kinds of hunting and running spiders there is much keen warfare.

Many spiders hide in crevices or in bivouacs of leaves which they roll up or bind together. McCook describes the nest of the Purse web Spider (*Atypus abbotii*), a purse-shaped tube attached to the bark of trees, with the outer surface dark and covered with sand. The nests of the trap-door spiders have lids which fit accurately, and are covered with moss, earth, and lichen; in fact the nests of a great number of species believed to be trap-door spiders have never been found. In many cases the vibratory sensitiveness of the web is such that an approaching enemy finds the spider forewarned. When *Argiope cophinaria* has not time to drop from her web to the ground, 'she makes use of another power—she will render herself invisible. The web begins to sway backward and forward; the rapidity of the motion increases; the outlines become indistinct, and within a few seconds of the first movement spider, web, and all have vanished from sight! Others, such as *Pholcus atlanticus*, hang by the legs, and whirl the body rapidly with the same bewildering result.' Mr Herbert Smith suggests that the sideways movement of the *Laterigradæ* has a protective value, since the enemies are likely to allow for a forward movement of their prey. Many Epeiridæ and other spiders drop to the ground when danger threatens, and remain motionless on a surface which they often resemble in colour. McCook seems inclined to regard this death-feint as a trick, not as fear paralysis or catalepsy. The cocoons are hidden in crevices, or covered with web and debris, or carried about by the mother—sometimes attached to the abdomen, sometimes in the jaws. For further examples of the thousands of protective habits, see the works of the Peckhams and Dr McCook.

Often the forms and colours of spiders have a protective resemblance to pieces of plants or to dead things. The species of Uloborus are like small pieces of bark; *Hyptioides cavatus* resembles a bit of dirt or the ends of the dead pine branches among which it lives; *Cyrtophora conica* is hardly distinguishable from the pieces of light rubbish which it accumulates in its web; *Cærostris mitralis* resembles a woody knot on the branch on which it rests; *Thomisus foka*, a species much dreaded in Madagascar, has a very strange,

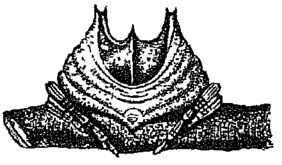

Fig. 4.—*Cærostris mitralis* on a branch (after E. G. Peckham).

crab-like form, and resembles in colour and general appearance the fruit of *Hymenæa verrucosa*, a tree common in the forests where this spider is found; *Drapetisca socialis* is very like the bark of birches and other trees on which it lives; among the Lycosidæ there are scores of dull-coloured species that live on the ground; Dr McCook describes one form which has a tint like that of the water upon which it is constantly found; about a dozen species which live on leaves are recorded as protectively green; many Thomisidæ are coloured like the flowers on which they await their victims; *Ornithoscatoides decipiens*, first described by Forbes, is, as its name suggests, most deceptively like bird-excrement, so that the discoverer actually plucked the leaf on which the spider was resting, and looked at it for some moments before he discerned his captive. In short, what Mr Wallace said about the leaf-like butterfly is often true of spiders: ‘Size, colour, form, markings, and habits all combine to produce a disguise which may be said to be absolutely perfect.’

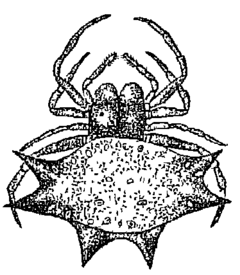

Fig. 5.
Gasteracantha rufospinosa, female, mag. 2½ diameters.
(After E. G. Peckham.)

Again, there are spiders which are rendered inedible by an armature of spines and plates, and many of these (e.g. some Gasteracanthidæ) are very brilliantly coloured. It is possible that their conspicuousness impresses their enemies with the fact that they are better left alone.

Lastly, there are spiders which exhibit a protective mimicry of animal forms. ‘Spiders most commonly mimic ants,’ Mrs Peckham says; ‘but we hear also of their imitating beetles, snail-shells, ichneumon and horse flies. There is also a curious Madagascar species which looks exactly like a little scorpion, the resemblance being heightened by the habit of curving its flexible tail up over its back when irritated.’ Nearly all the species of Coccorhestes and Homalattus resemble beetles; Cytarachne is like a snail-shell; *Synagelcs picata* and *Synemosyna formica* are good examples of those which have a mimetic likeness to ants.

Classification.—Spiders of the Bird-catcher (Mygale) type differ from all the others in having four pulmonary sacs (Tetrapneumones). The Dipneumones, which form the vast majority, including several thousand species, are conveniently classified according to their habits whether sedentary or wanderers, and according to their spinning-work, this physiological classification being also justified anatomically. Another fact of some importance is the presence or absence of a cribellum. Thus we distinguish

‘Sedentary’
Sub-order—TETRAPNEUMONES.
Tribe I.—Territelariæ: Tunnel-weavers.
Sub-order—DIPNEUMONES.
Tribe II.—Tubitelariæ: Tube-weavers, including Ecribellatæ and Cribellatæ.
Tribe III.—Retitelariæ: Line-weavers.
Tribe IV.—Orbitellariæ: Orb-weavers, including Ecribellatæ and Cribellatæ.
‘Wanderers’
Tribe V.—Laterigradæ.
Tribe VI.—Citigradæ.
Tribe VII.—Saltigradæ.

Numerous extinct species of spiders have been obtained from Tertiary deposits, especially from amber. The oldest known form (Protolycosa) occurs in Carboniferous strata.

British Species.—Among the British species the following may be noted: The Common Garden Spider (*Epeira diadema*), and other species of this genus; the House-spiders (*Tegenaria domestica* and *T. civilis*); *Agelena labyrinthica*, which makes large cobwebs, very abundant on heaths; the Water Spider (*Argyroneta aquatica*), which inflates its sub-aquatic dome-shaped web with air brought from the surface entangled among the hairs of the spider's body; the Green Crab-spider (*Sparassus smaragdulus*), whose young are fond of ballooning in autumn evenings; a few Wolf-spiders, such as *Lycosa piratica* and *Dolomedes fimbriatus*; *Salticus scenicus*, exceedingly common on walls and fences, and *Atypus sulzeri*, the only British representative of the Trap-door Spiders (see Systematic List: P. Cambridge, *Proc. Linn. Soc.*, xxx. 1875).

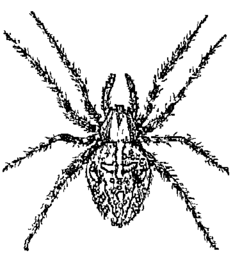

Fig. 6.—The Garden Spider (*Epeira diadema*).

Relations to Man.—The wide-spread prejudice against spiders is not scientifically justifiable. We must admire their dexterity, their instinctive aptitudes, their intelligence, the beauty of their architecture, the elaborateness of their courtship (tragic as it sometimes is for the suitor), and their maternal care. Although there are countless tales of ‘black spiders,’ rarely preserved for identification, which are alleged to have given dangerously poisonous bites, this is not true except in regard to the famous Tarantula (*Lycosa tarantula*), and even the effects of its bite have been grossly exaggerated both by evil intention and credulous superstition. Of a not uncommon line-weaver (*Lathrodectus oculatus*), which has a very bad reputation as a venomous biter, one of the authorities on spiders says that he repeatedly allowed himself to be bitten and suffered no inconvenience. In fact, if we except the Tarantula, there are few spiders more dreadful than are fleas. In old medical practice a spider was sometimes applied to the wrist in cases of fever, and another custom of applying *the web to staunch bleeding* is still practised by schoolboys, who are happily ignorant of antiseptic precautions. The great value of spiders is the obvious one that they destroy so many insects; thus, McCook counted thirty-six mosquitoes *on* a single web.

See especially McCook, *North American Spiders and their Spinning-work* (2 vols. Phila. 1889-90); also Bertkau, numerous papers trans. in *Annals and Magazine of Natural History*; Blackwall, *British Spiders* (Lond. 1861-64); E. Blanchard, *Arachnides* (Paris, 1853-61); P. Spiegeleisen. See BESSEMER STEEL.

Spielberg. See BRÜNN.

Spielhagen, FRIEDRICH, German novelist, was born at Magdeburg on 24th February 1829, but passed all his youth at Stralsund. From the gymnasium there he proceeded in 1847 to the universities successively of Bonn, Berlin, and Greifswald, afterwards settling at Leipzig in 1854 as a *docent*, at Hanover in 1859, and at Berlin in 1862, in the last two places till 1884 as a newspaper editor. His works, of which eight have been translated into English, are some thirty in number, in upwards of fifty vols., and include (besides poems, books of travel, translations, and novelettes) *Problematische Naturen* (1860), *Durch Nacht zum Licht* (1861), *Die von Hohenstein* (1863), *In Reih und Glied* (1866), *Hammer und Amboss* (1868), *Sturmflut* (1876), *Uhlenhans* (1884), *Was will das werden?* (1886), &c. Mostly 'novels with a purpose,' dealing with burning questions of the day, these have a vigour and interest, in spite of their sometimes portentous length, that too often are missing in modern German fiction. A complete edition of his works has been published since 1875.

See his autobiographical *Erinnerungen* (1889 *et seq*.), and Karpeles' *Friedrich Spielhagen* (Leip. 1889).

Spigelia, a genus of plants of the natural order Loganiaceæ, having a calyx glandular inside, a long slender valvate corolla, long filaments, and a capsule of two *cocci*, splitting around at the base. *S. marilandica*, often called Worm Grass and Carolina Pink, is a native of the southern United States, a perennial plant with a simple quadrangular stem. The root (Pink Root) is purgative, narcotic, and poisonous, but is a powerful vermifuge, and is very commonly employed in the United States. *S. anthelmia*, an annual, native of tropical America, with very small purplish flowers, in spike like racemes, possesses similar properties. The efficacy of both is, however, impaired by keeping; and they are apt to produce unpleasant symptoms when used as medicines. Other species are also known as poisons.

Spike, in Botany, that kind of inflorescence in which sessile flowers, or flowers having very short stalks, are arranged around an axis, as in the greater plantain, common vervain, common lavender, and some species of sedge. In rye, wheat, barley, darnel, and many other grasses there is a sort of compound spike—i.e. the flowers or fruits are arranged together in spikelets upon short stalks, which again surround the top of the culm in the form of a spike. The catkin, the spadix, and the cone may be regarded as varieties of the spike.

Spikenard, or NARD (Gr. *Nardos*), a perfume highly prized by the ancients, and used both in baths and at feasts. It was brought from India, and was very costly. The plant which produces it is the *Nardostachys Jatamansi*, a small plant of the natural order Valerianaceæ, a native of the Himalaya Mountains of the north of India, and found at least as far south as the Deccan. The odour is not, however, generally agreeable to Europeans. Spikenard is popularly believed to have the power of promoting the growth and blackness of the hair, and to be an antidote for poisons. It is now more used medicinally than as a perfume. The aromatic hairy tap-root, which is from 3 to 12 inches long, sends up many stems with little spikes of purple flowers, which have four stamens. The name spikenard was given by the ancients to many perfumes used as substitutes for the true or Indian spikenard, some of which were derived from the roots of plants of the same natural order, the kind called Gallic or Celtic spikenard from those of *Valeriana celtica* and *V. saliunca*, which are still used in the East for perfuming baths, and that called Cretan spikenard from those of *V. tuberosa*, and *V. Phu*. All of these grow on the Alps and other mountains of the south of Europe, and the peasantry of Styria and Carinthia collect them from rocks on the borders of perpetual snow. They are tied in bundles, and sold at a very low price to merchants, who sell them at a great profit in Turkey and Egypt, from which a proportion is transmitted even to India.

Spiking is the operation of quickly rendering a muzzle-loading gun useless, resorted to by troops compelled to abandon their own pieces or unable to remove those of the enemy which they have captured. The process consists in driving a cast-iron spike into the vent or touch-hole and then breaking it off short with a hammer. A spiking party of artillerymen always accompanied a storming party. To render a spiked gun again serviceable it was generally necessary to drill a fresh vent. Breech-loading guns are best rendered temporarily unserviceable by removing part of the breech mechanism.

Spilsby, a market-town of Lincolnshire, 10 miles by rail NE. of Boston, stands on the edge of the Wolds. The church contains interesting monuments of the Willoughby family (1348–1610), and the market-place has a bronze statue of Sir John Franklin, a native of the town. Pop. 1482.

Spinach, or SPINAGE (*Spinacia*), a genus of herbaceous plants of the natural order Chenopodiaceæ; *diœcious, the male flowers consisting of a* four-parted perianth, and four stamens; the female, of a two to three cleft perianth, and an ovary with four styles; the perianth hardening around the fruit as it ripens; the fruit an achenium. Common Spinach, or Garden Spinach (*S. oleracea*), is in general cultivation for the sake of its young leaves, which are a favourite and wholesome vegetable, prepared either by boiling or by frying with a little butter. Two very distinct varieties are cultivated—Prickly Spinach, which has the leaves somewhat triangular and arrow-headed, and the fruit rough with prickle-like projections; and Smooth Spinach, or Round Spinach (*S. glabra* of some botanists), with the leaves more round and blunt, and the fruit smooth. Spinach is an annual. Its stem rises to the height of from 2 to 4 feet; the male flowers are in long spikes, the female in clusters close to the stem. After the stem begins to be developed the leaves become bitter and unfit for use. This bitterness appears also at an earlier period in dry weather or in poor soil; and the more luxuriantly spinach grows the better it is. It is sown in spring, and is ready for use in a very short time; or it is sown in autumn, thinned out, and used early in spring. The smooth spinach

Common Garden Spinach (*Spinacia oleracea*).

is very generally preferred for the former purpose, and the prickly kind for the latter; but a somewhat intermediate variety called Flanders Spinach, in the seed trade named Viroffley Spinach, is now often used for both, being particularly esteemed for the large size of its leaves. The native country of spinach is not well known, but is believed to be some part of Asia, as the plant was introduced by the Arabs into Spain, and thence diffused over Europe. Another species (*S. tetrandra*) is cultivated and much esteemed in India. The name spinach is also given to a number of other plants of very different botanical characters, but which have the same bland and nutritious qualities, and are used in the same way. New Zealand Spinach is *Tetragonia expansa*, a plant of the natural order Mesembryaceæ, sub-order Tetragonieæ (natural order Tetragoniaceæ of Lindley), a trailing, succulent annual, spreading widely over the surface of the ground, and producing a great abundance of stalked ovate-rhomboid leaves. The young stems and leaves of this plant are much used in New Zealand, and have now come into very general use also in other parts of the world as a kind of spinach. It is cultivated in the middle and south of Europe and in Britain, succeeding well even in Scotland with the slightest aid of a hotbed in spring, and is found particularly useful in light dry soils, in which in summer it is difficult to maintain supplies of the common spinach. Patience Dock, or Garden Patience (*Rumex Patientia*; see DOCK), is called in Germany English Spinach, and was formerly much cultivated in England, but is now neglected.

Spinal Column and Spinal Cord. The spine or spinal column is the most important and characteristic part of the Skeleton (q.v.) of the highest division of the animal kingdom. It is composed of a series of bones placed one above, or in front of another, and called vertebræ; and hence these animals, having this distinguishing characteristic in common, are all included in the term *Vertebrates*. The vertebræ vary greatly in number in different animals, and even in members of the same class, and the number bears no apparent relation to the other organs of the animal. Moreover, in their shape they differ extremely even in different parts of the same spine, in accordance with their special functions. In man the number of vertebræ which collectively form the spinal column is 7 in the neck (cervical vertebræ), 12 in the back (dorsal vertebræ), 5 in the loins (lumbar vertebræ), all of which are capable of being detached from one another, and are termed *true* vertebræ; and 5 vertebræ ossified together and forming the sacrum, and 4 or 5 similarly united forming the termination of the column, and constituting the bone called the coccyx, which are known as *false* vertebræ. However long or short the neck may be, every mammal has 7 cervical vertebræ, excepting the three-toed sloth which has 9, and the sea-cow which has 6. In the other regions of the spine no such uniformity exists. Each vertebra is attached to the two between which it lies by numerous strong and more or less elastic ligaments, and between each pair of vertebræ there is interposed a lenticular disc of fibro-cartilage, which acts as a buffer. By these arrangements the spinal column is rendered highly elastic, the communication of jars or shocks is prevented, and a very considerable general range of movement permitted, although the motion between any two adjacent vertebræ is slight. The elasticity of the column is further increased by the component vertebræ being arranged in curves instead of being placed perpendicularly. The curves should be exactly in the antero-posterior direction, any well-marked lateral deviation from the perpendicular being abnormal; but a very slight lateral curvature with the convexity to the right may often be detected in the upper and middle parts of the back, and is supposed to be dependent on the more frequent use and greater strength of the right arm as compared with the left. From their position they are termed the cervical, dorsal, lumbar, and pelvic curves. The dorsal and pelvic curves have their concavities in front, and thus enlarge the spaces in which the thoracic and pelvic viscera are contained; the two other curves are convex anteriorly, and thus afford support to the parts above them. The upper three curves are so arranged that their cords are in the same vertical line in the erect position of the body, and this vertical line corresponds with the line of gravity of the head. The cause of these curves is to be sought for partly in the shape of the vertebral bodies, and partly in that of the intervertebral substance. Amongst the uses of these curves it may be mentioned (1) that they enable the spine to bear a greater vertical weight than it could otherwise maintain; it is calculated that nine times as great a vertical force is required to bend it as if it had been straight; (2) that they facilitate the movements of the body, especially in the act of running; and (3) that they are so disposed as to protect the cord in movements of the spine. Similar curves are seen in the spine of other mammals (see ANTHROPOID APES), though the degree of flexure is liable to great deviations. The lumbar curve, which has especial reference to the erect position, is always much less marked than in man.

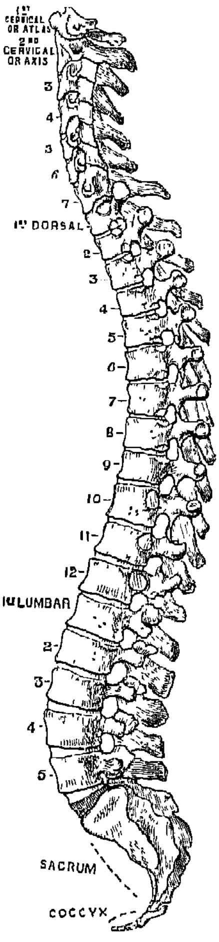

Fig. 1.—Spinal Column.

The vertebral canal formed by the apposition of the spinal foramina or neural arches, and containing and protecting the spinal cord, varies in its size at different parts of the column. It is largest in its antero-posterior diameter in the neck and loins (measuring at the last lumbar vertebra ⅞ of an inch), where the antero-posterior movements of the spine are greatest, and where the cord is least closely attached to the vertebræ; while in its lateral diameter it is greatest at the atlas, where it measures nearly an inch and a half. A transverse section of the canal is nearly circular through the greater part of the back. The intervertebral foramina through which the nerves emerge vary in shape and position in different parts, but are always of sufficient size to prevent injurious pressure on the nerves during movement of the spine; and in the dorsal region, which is the ordinary seat of angular curvature, the nerves are so protected by bony arches that they may escape injury, even when the bodies of several dorsal vertebræ have been destroyed by ulceration.

The *spinal cord* is that part of the central nervous axis which is contained within the vertebral or spinal canal. In man it extends from the foramen magnum, where it becomes continuous with the medulla oblongata, as far down as the lower border of the first lumbar vertebra. Below this point it is continued as a narrow thread containing little nervous matter, the *filum terminale*. The cord is, like the brain, encased in a triple sheath of membranes, the pia, arachnoid, and dura mater, the last two of which are less closely opposed to the cord and the vertebral column than they are to the brain and the cranium. The cord is a somewhat flattened cylinder or column of a whitish colour. It is divided into two lateral halves by an anterior median fissure and a posterior median septum. The former is less deep but wider than the latter, which is merely a process of pia mater. From each side of the cord thirty-one pairs of spinal nerves arise, each by an anterior and a posterior root (see NERVOUS SYSTEM). The cord is not of uniform circumference throughout. There is a slight thickening where the brachial nerves, and another where the lumbar nerves, arise. These are termed the brachial or cervical and *lumbar enlargements* respectively. The nerve roots in the cervical and dorsal regions pass nearly transversely outwards through the intervertebral foramina; but the lumbar and sacral nerves are directed downwards to attain their points of exit, in such a manner as to obtain the name of *Cauda Equina*.

The cord is seen to be composed of white and gray matter. On a transverse section the gray matter is found in the centre to present the appearance of a double crescent, concave outwards, with a commissural band between the two sides, so that the whole somewhat resembles the letter H. In the gray commissure is the *central canal*, which extends throughout the whole length of the cord and becomes continuous above with the fourth ventricle. The gray matter is divided into an anterior and a posterior horn. It is composed of a basis of connective tissue in which are a fine felt-work of nerve-fibres and nerve-cells. In the anterior horn, which becomes specially developed in the brachial and lumbar enlargements, the cells are of the multipolar type. They send a well-marked axis cylinder process into the anterior nerve root, and by their other processes are connected with fibres which descend from the cerebrum and from the posterior roots and other sources. In the posterior horn the nerve-cells are smaller, rounded, or spindle-shaped, and possess no axis cylinder process. They are probably connected with the posterior roots.

The white matter of the cord is composed of nerve-fibres, united by a small amount of connective tissue. The fibres have mostly a longitudinal direction, with the exception of a small strand which crosses from one side to the other at the bottom of the anterior median fissure—the anterior white commissure. Each half of the cord is divided by the anterior and posterior roots into three columns, named anterior, lateral, and posterior. Though these look almost exactly alike both to the naked eye and under the microscope, they can, by taking advantage of the facts that their component fibres are not all developed simultaneously, and that as the result of injury they do not 'degenerate' in the same direction or to the same extent, be further subdivided. Thus the posterior column is composed of two tracts—a postero-median and a postero-lateral. In the lateral column there can be distinguished five tracts: a direct cerebellar, an ascending antero-lateral tract, a crossed pyramidal tract, a lateral limiting layer, and a lateral mixed zone; while the anterior column consists of a direct pyramidal tract and an anterior mixed zone. The relations of these tracts have been fairly definitely established. The postero-median column is nearly entirely composed of fibres of the posterior roots which, after entering the cord and passing for a short distance in the postero-external column, are continued upwards as high as the medulla oblongata, where they end. This column then will form a direct path of connection of the posterior roots with the medulla oblongata. The direct cerebellar tract connects a column of nerve-cells in the posterior horn of the lumbar and dorsal regions of the cord (which is termed Clarke's vesicular column) with the middle lobe of the cerebellum. The antero-lateral tract appears to connect the nerve-cells in the posterior horn of one side of the cord with the medulla oblongata of the opposite side.

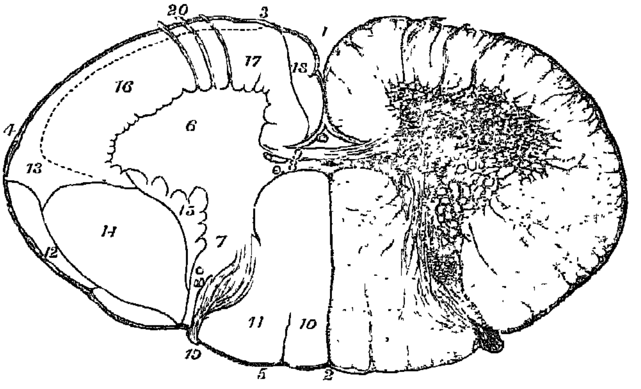

Fig. 2.—Section of Spinal Cord (outline of tracts shown on left side):
1, anterior median fissure; 2, posterior median septum; 3, 4, 5, anterior, lateral, and posterior white columns; 6, 7, anterior and posterior horn of gray matter; 8, 9, anterior and posterior commissures; 10, posterior median column; 11, posterior lateral column; 12, direct cerebellar tract; 13, antero-lateral ascending tract; 14, crossed pyramidal tract; 15, lateral limiting layer; 16, 17, lateral and anterior mixed zone; 18, anterior pyramidal tract; 19, posterior, and 20, anterior roots.

All these tracts degenerate, and presumably also conduct nervous impulses in an upward direction. The direct and crossed pyramidal tracts form the downward continuation of the 'motor'-fibres from the surface of the brain to the cells in the anterior cornu of the cord. At the lower end of the medulla oblongata (see BRAIN, fig. 7) the greater part of the fibres of the anterior pyramids cross the middle line and descend in the crossed pyramidal tract of the cord to become connected with the motor-cells in the anterior horn. The direct pyramidal tract represents a small remnant of the fibres which descend in the cord without crossing to the opposite side. They cannot as a rule be traced further than the cervical region. Both of these tracts are undoubtedly concerned in the transmission of voluntary motor impulses from the brain. Their degeneration always accompanies paralysis of cerebral origin.

The tracts which lie in immediate contact with the gray matter, the antero-lateral mixed zone, the lateral limiting layer, and the postero-external column, probably form connections between different levels of the cord. Thus the postero-external column is in great part formed of fibres of the posterior roots passing upwards or downwards for a certain distance in it before entering the postero-internal column; while the antero-lateral mixed zone contains fibres which connect either nerve-cells at different levels, or more probably nerve-cells of one level with fibres which enter the anterior roots at another.

Functions.—The spinal cord provides paths for the conduction of afferent and efferent impulses to and from the brain, and also between different portions of its own substance, as well as arrangements for co-ordination of movements of the muscles of the trunk and limbs, and centres for the regulation of certain of the 'organic' functions of the body.

The efferent impulses are motor, vasomotor, and secretory. The path for the first of these is perfectly well known. It passes from the cerebral cortex (motor area) through the internal capsule and the anterior pyramids of the medulla mainly to the crossed pyramidal tract of the opposite side, and thence, as described, to the cells in the anterior cornu. It is not yet known whether the ultimate destination of the fibres of the direct pyramidal tract is the cells of the anterior horn of the same or those of the opposite side. The fibres from the vasomotor centre in the medulla in all probability pass down in the crossed pyramidal tract and leave the cord by the anterior roots. Division of their path leads to paralysis of the muscular walls and dilatation of the arteries. This is only temporary, as there are probably also centres in the cord which can act independently of those in the medulla. The other efferent paths are unknown.

The afferent paths transmit the various forms of sensory impulses; but, though we may perhaps assume that those which degenerate upwards also conduct in the same direction, it is remarkable how little is known definitely about these. It is generally held that impulses from the muscles pass up the same side of the cord either in the postero-median or direct cerebellar tracts; while the other sensory paths cross the cord as soon as they enter it, and are continued upwards along the other side. It is not determined whether the crossing is complete, or whether the path is in the white or gray matter or in both. Probably it is not identical for each variety of sensation. There is some reason to believe that impulses which give rise to painful sensations travel up the ascending antero-lateral tract.

The cord also has in its anterior cornu cells which, when stimulated either from the brain or from the sensory nerves, originate voluntary or reflex muscular movements. These cells fulfil too the function of keeping up the general tone of the muscles and also their nutrition, for when they are destroyed the nerves and muscles connected with them waste and disappear. In certain regions of the cord these cells form centres for various of the organic functions. These are found mostly in the lower dorsal and lumbar regions. Recent experimental research by Ferrier and Yeo has determined the levels in the cord of the centres for the various movements of the limbs and trunk, and has already given valuable results in practical surgery.

See Quain's *Anatomy*, Obersteiner's *Anatomy of the Central Nervous Organs* (Hill's trans.), Landois and Stirling's *Physiology*, and Foster's *Physiology*.

CURVATURE OF THE SPINE.—There are two main forms of this disease, which are due to different causes—viz. Angular Curvature or Pott's Curvature, and Lateral Curvature.

Angular curvature, which was first described by the famous surgeon Percival Pott (1713-88), and is hence often named after him, is due to disease of the bodies of the vertebræ and of the intervertebral discs. It usually takes the form of a tubercular disease of the bones, which become carious and destroyed, and of ulceration of the discs between them. The result is that the bodies of the diseased vertebræ give way and the column becomes bent forward on itself, while the spinous processes form a backward projection opposite the diseased part—hence the name angular curvature. This projection is most marked when the disease is in the dorsal region of the spine. If the disease is arrested the bones become firmly united, and the curve of the spine becomes permanent. In unfavourable cases abscesses may develop in the neighbourhood, and either press on the spinal cord or on the spinal nerves, or burrow in various directions, notably in the lumbar region (psoas abscess). The disease is often set up by an injury which may be severe, such as the falling of a heavy weight on the back, or in children may be some trifling twist or fall, such as may occur during rough play or from falling out of bed or from a chair. It most often occurs in delicate children with a tubercular family history, but it is by no means unknown in those whose family and personal history is quite unexceptionable, and it may even affect adults. Its early symptoms are often obscure, and consequently may be overlooked at a time when treatment is of most avail. There is at first little or no deformity, but there may be pain on percussing the spine of the affected vertebræ. There is also usually an avoidance of all movements which may lead to jarring of the spinal column or to painful pressure on the nerves. If the vertebræ of the neck are affected the child often supports its chin by the hands, and does not willingly turn its head round. Disease of the dorsal or lumbar vertebræ is generally indicated by cautious movements, especially in coming down a stair, the avoidance of stooping or bending, or sudden twisting of the body. A child will thus get down on its knees to pick anything off the floor rather than stoop.

The treatment requires to be both local and constitutional. It is always protracted for months or even years. The general treatment is mainly that required for strumous constitutions, such as codliver-oil, iron, hypophosphite of lime, &c. The local treatment involves absolute rest in the recumbent position in the early stage, with counter irritation over the spine in the neighbourhood of the disease. In later stages mechanical supports are also required to keep the vertebræ from pressing on each other. The kind of support needed varies with the region affected; one very valuable form for hospital practice consists in the application, during the suspension of the patient, of a plaster of Paris jacket to the body. The more carefully rest in the recumbent position and mechanical support are carried out, the less, as a rule, will be the resulting deformity, the greater the prospect of avoiding complications and of obtaining permanent cure.

Lateral curvature consists in a twisting of the bodies of the vertebræ on each other round their vertical axis. It is sometimes a result of rickets, but is far more frequently developed in growing girls of feeble muscular development and general health, between the ages of ten and sixteen. It is produced in the first instance by the continued maintenance of asymmetrical positions of the body, such as by sitting sideways or cross-legged before a school-desk, or by carrying a weight on one arm. This curvature is usually to the right in the dorsal region with a corresponding twist to the left in the lumbar region. One shoulder, usually the right, becomes elevated, and the scapula projects, while the right side of the chest becomes rounded and the left side flattened. The lungs and liver become compressed and subject to disease, and the gait becomes awkward. This disease is due in the first instance to rotation of the bodies of the vertebræ on each other as the result of the irregular pressure. Later the ligaments and articular processes of the vertebræ undergo permanent changes, while the muscles may atrophy or undergo fatty degeneration. The ribs also become distorted, those at the side of the convexity of the curve bending at the angles, those at the other side becoming flattened.

The treatment of this form differs entirely from that of angular curvature. As the disease is due to the continuance of asymmetrical positions of the body, combined with muscular and general debility, general tonics, fresh air, and gymnastic exercise specially directed to the strengthening of the weakened muscles must be adopted. In the later stages, when the deformity has become more confirmed, mechanical supports may be required as an adjuvant to the above.

SPINA BIFIDA is a congenital malformation occurring perhaps more frequently than any other except hare lip, and arising like it from arrest of development. It may be regarded as a congenital hernia of the membranes of the spinal cord through a fissure in the wall of the bony canal. A tumour is thus formed, which is usually of a roundish shape varying in size from that of an egg to that of an adult head, lying in the middle line of the back, fluctuating, and adhering to the adjacent vertebræ either directly or by a pedicle. The usual termination of the disease is death. As the size of the tumour increases, fatal convulsions ensue; or the skin investing the tumour may ulcerate and the contents escape, in which case palsy or convulsion produces death. Occasional cases are, however, recorded in which patients with this affection have survived till middle life. Surgical treatment has, until quite recently, been unsatisfactory; but with improved modern methods successful results have in many cases been obtained. Moderate support by means of a hollow truss, or a well-padded concave shield, may tend to keep the disease stationary; and any interference beyond this is, in the great majority of cases, unadvisable. For other diseases connected with the spine, see MENINGITIS, MYELITIS, LOCOMOTOR ATAXIA, &c.

Spinazzola, a city of Southern Italy, 30 miles SW. of Bari. It was the birthplace of Pope Innocent XII. Pop. 10,353.

Spindle-tree (*Euonymus*), a genus of plants of the natural order Celastraceæ. This order contains about 260 known species, all small trees or shrubs. The genus Euonymus has a lobed capsule and seeds surrounded by an aril, which in some of the species is remarkable for its brilliancy of colour. The Common Spindle-tree (*E. europæus*), a native of Britain, chiefly of the southern parts, and of great part of Europe, is very ornamental when in fruit, and its aril is of a fine orange colour. It is a shrub rather than a tree. The wood is hard and fine-grained. It is used for the finer articles of turnery and for skewers. It was formerly used for making musical instruments and for spindles, whence the name of the shrub. In Germany the shoots are bored for stems of tobacco-pipes. Charcoal made of it is much valued for crayons.

Spinel is a mineral composed chiefly of magnesia and alumina, and crystallising in octahedra. There are several varieties, which differ in chemical composition owing to isomorphous substitution, sometimes of the protoxides, but usually of the sesquioxides. *Ruby* or *Magnesia Spinel* is clear red or reddish, and contains little or no iron; *Pleonaste* (*Ceylonite*), or *Iron-magnesia Spinel*, is dark green to black, containing iron; *Picotite*, or *Chrome Spinel*, is black, containing chromium oxide; *Gahnite*, or *Zinc Spinel*, is green to brown, containing zinc; *Hercynite*, or *Iron Spinel*, is black, and occurs massive, in this variety ferrous oxide replacing magnesia. Ruby spinel occurs as crystals imbedded in granular limestone, also with calcite in serpentine and in various crystalline schists, as also in the alluvial sands, &c. derived from the disintegration of these rocks. Pleonaste is an occasional constituent of eruptive rocks, and also of certain rocks which have undergone alterations from contact with eruptive masses. Picotite has been met with in basalt, but is more commonly seen in peridotite. Gahnite is of sparing occurrence in certain crystalline schists, while Hercynite is occasionally found in such rocks as granulite. The finer varieties of spinel are prized as gems—the red coloured ones being commonly called rubies. See RUBY.

Spinello Aretino, an Italian painter, was born at Arezzo about 1330, his father being a Ghibelline exile from Florence. The painter spent nearly all his life between his birthplace and his father's city, and died at Arezzo about 1410. His principal frescoes were done for the sacristy of the church of St Miniatus near Florence, for the *campo santo* (cemetery) of Pisa, and for the municipal buildings of Sienna (a series illustrating the Italian wars of Frederick Barbarossa), with several others in and near Arezzo. Spinello enjoyed a great reputation in his own day, being compared, and by some preferred, to Giotto, whose style his own in some respects resembles. Unfortunately his frescoes have mostly disappeared; and his panel and easel pictures, of which there are several in the galleries of Europe, do not equal his frescoes in excellence.

Spines. See THORNS.

Spinet. See HARPSICHORD.

Spinifex, or PORCUPINE GRASS (*Triodia irritans*), a very coarse, hard, and spiny grass which grows in tussocks, and in some interior parts of Australia covers hundreds of square miles at a stretch. This grass cannot be eaten by any animal, and as the clumps are three or four feet high they make exploring and travelling very laborious. Horses are badly lamed by the wounds from the spinifex.

Spinning is the art of twisting fibrous substances into rounded strands of yarn fitted for weaving, or for thread or rope making. To form such strands two operations are essential—(1) the drawing out of uniform quantities of fibre in a continuous manner, and (2) twisting the material so drawn out to give it coherency and strain-resisting power. The earliest and for ages the only spinning apparatus was the spindle with the distaff. The latter was a stick or staff upon which a bundle of the fibre to be spun was loosely bound, and it was either held in the left hand or stuck in the belt. The spindle (fig. 1) was a smaller tapering rod, the rotation of which gave the twist, and around which the thread was wound as it was twisted. The twist was given by causing the spindle to rotate against the person, and allowing it to fall towards the ground whilst spinning around. To give the spindle increased momentum it was weighted with a whorl (fig. 1) of stone or metal, but as the weight of the yarn on it increased this make-weight

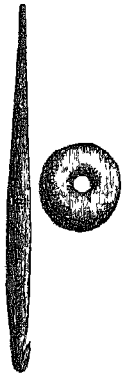

Fig. 1.—Spindle and Whorl.

was removed. A graphic description of this method of spinning is given by a Scotch rhymester of the 18th century.

> To save their plaiding coats some had
> Upo' the haunch a bonnet braid
> Or an auld wecht or kaiding skin
> To rub and gar the spindle rin
> Down to the ground wi' twirling speed
> An' twine upo' the floor the thread.

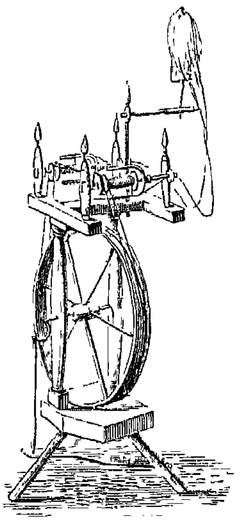

Fig. 2.—Two-handed Spinning-wheel.

Simple as it is, the spindle has continued in use from prehistoric times to the present day. In some outlying regions of the Scottish Highlands and Islands, according to Sir Arthur Mitchell (*The Past in the Present*, Rhind Lectures, Edin. 1880), yarn is still made with it, and in the East Indies the exceedingly delicate yarn for Dacca (q.v.) muslins is made on the spindle. The first improvement on this simple apparatus consisted in fixing the spindle in bearings and causing it to rotate by a belt passed over a wheel. Next came the fitting on the spindle of a separate bobbin to receive the spun yarn, and this in effect constitutes the charka or spinning-wheel of the East, which has there been used from time immemorial, and also the 'muckle wheel,' the use of which continued in Scotland till recent times. This simple wheel was known in Europe as early as the 14th century, but the greatly improved small or Saxon wheel (fig. 2), with a treadle motion giving continuous rotation to the spindle and allowing the spinner to sit with both hands free, was not known till much later times. In the spinning-wheel in its improved form a bobbin or pirn with a separate motion was placed on the spindle (fig. 3), which had two bent arms, the flyer or flight, for winding the yarn on the bobbin. The bobbin and flyer revolved at different rates—the revolutions of the spindle giving the twists and the difference of rotation causing the winding on. In such wheels it was possible to have two spindles and pirns a little apart (the two-handed wheel, fig. 2), with distaff or rock between them, and on these the spinster produced thread with each hand. The introduction of mechanical spinning towards the end of the 18th century gave a death-blow to this great domestic industry, but in the Northern and Western Highlands of Scotland a good deal of worsted yarn still continues to be made for local manufactures on spinning-wheels.

The series of inventions which overthrew hand-spinning may be said to have been begun by Lewis Paul in 1738, when he patented the important principle of drawing out and attenuating a sliver or loose coil of fibre by passing it between successive pairs of rollers revolving at increasing rates of velocity. This principle of drawing out fibres by accelerated motion was developed in the spinning-frame or throstle invented by Arkwright in 1767, and it forms a fundamental feature of all modern spinning machinery. About 1764 James Hargreaves at Standhill, near Blackburn, invented his *spinning-jenny* (fig. 4), an apparatus by which eight threads could be spun at once, and this was soon improved upon until eighty could be produced as easily. In this apparatus a number of large reels filled with thickish coils of fibre called rovings were set on upright fixed spindles, and the end of these rovings was passed between two small movable bars of wood placed horizontally and under the control of the spinner, who could thus make them press more or less on the roving, and consequently increase or decrease the draw upon it from the spinning-spindles, which were set in a row at the other end of the frame. These spinning-spindles gave the twist to the rovings when they were fully drawn out, and thereafter wound on themselves the twisted yarn by being moved in the frame towards the bobbins of roving whilst they continued to rotate. The principle of the jenny was important and, developed in the spinning-mule of Crompton in 1779, it is the basis of the second of the two great methods of machine-spinning now in use.

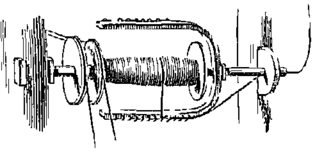

Fig. 3.—Spindle, Bobbin, and Flyer of fig. 2 on larger scale.

While the operation of spinning is one of the simplest of all arts, requiring as we have seen only the aid of two short pieces of stick, its modern developments have produced more delicate and varied mechanical devices, and have called forth more inventive ingenuity, than any other industrial operation. To convey an adequate idea of the variety of machines used in any single branch of the spinning trade, and of their highly complicated structure, would require much more space than can be here afforded. Different kinds of fibre require different treatment and special machines; and, moreover, yarns of the same fibrous material may be prepared and spun in several different ways according to the uses for which they are intended and other circumstances. Spinning thus becomes a complicated and delicate art, varying widely according to the material treated and the purpose to which the yarn is to be devoted. Dealing with wool, for example, the treatment of that fibre for the production of worsted and of woollen yarns is diametrically opposite. For worsted yarns long staple wools are employed. These are combed so

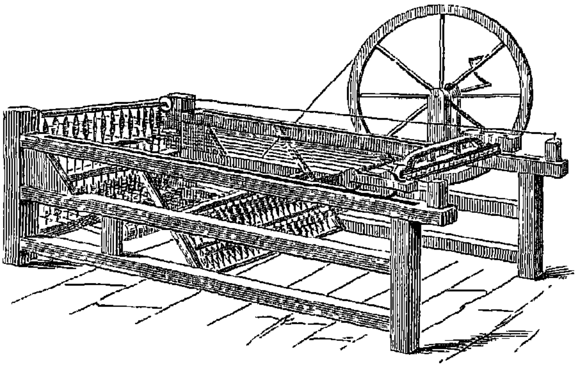

Fig. 4.—Hargreaves' Jenny.

as to separate the short fibres—the 'noils'—from the long or 'top' fibres. The 'top' afterwards passes through a long series of operations, the principal object of which is to lay every single fibre as nearly as possible parallel and level with its neighbour. For woollen yarn, on the other hand, short staple and wavy wools are used. These are carded together so that the fibres may as far as possible cross each other and interlace before being spun, and these peculiarities form the essential distinction between woollens and worsteds. Apart from worsteds, however, there is a general sequence in the treatment of all fibres which may be here briefly outlined.

The object of all operations preliminary to the actual spinning is (1) to free the fibres from all extraneous matter; (2) to lay them side by side in level parallel order; (3) to pull them out in a continuous strand or sliver of uniform thickness; and (4) to attenuate this sliver till the quantity required to form the yarn is reached. The operations necessary for these purposes, combined with a properly regulated amount of twist, constitute the conditions necessary to produce sound, level, and uniform yarn.

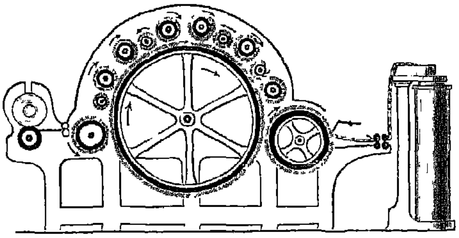

Fig. 5.—Sections of Carding-engine.

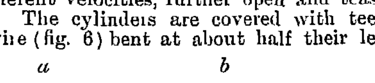

Fig. 6.
a, card wire, b, card setting.

Taking the case of cotton, the opening and partial cleaning of the matted fibres are secured by passing the material through two machines called *respectively the opener and the scutcher*. In these machines are cylinders revolving at a high rate of speed, with their surfaces studded with stout teeth which seize separate flocks of the fibre and carrying it round form a broad uniform teased mass which is called a lap. In the first of these machines it is also submitted to a strong current of air which blows dust and dirt out of the cotton. From the scutcher a well opened and spread lap of the fibre is delivered to the carding-engine (fig. 5), in which a series of cylinders of various sizes, and rotating at different velocities, further open and tease the fibre. The cylinders are covered with teeth of fine wire (fig. 6) bent at about half their length, of which there may be from six to seven millions in a single machine. According to the direction in which the cylinders rotate, and the rate of their revolution, the wire points may meet each other, or the points and flat sides of the wires may meet and pass; and in this way certain cylinders lift the fibres from their neighbours and pass it on to others, so that the fibre is gradually teased, brushed, and spread out in a uniform manner. From the carding-engine the fibre is delivered in a broad lap; but by passing it through a ring or tube it is compressed into a soft rounded coil or sliver. This sliver is taken to the drawing frame, which consists of say four successive pairs of rollers, each pair in succession going at a greatly accelerated rate, so that the last pair may be going six times quicker than the front pair. In this way a sliver is drawn out six times its original length, and six slivers fed in come out the thickness of one. This drawing out ultimately brings the slivers to a very uniform thickness, and places the fibres in a parallel order. It may be repeated many times, and thereby the fibres which lay together in the original strand may be drawn out to a great length. Thus, passing a sliver of one yard three times through the drawing frame elongates it 6 × 6 × 6 = 216 yd., or four times passed through it is stretched out to 1296 yd. For fine yarns this drawing out frequently repeated may represent an elongation many thousandfold. In the slubbing-frame comes the beginning of the spinning process: the sliver being here further drawn out and twisted sufficiently to enable it to be wound on a bobbin. The intermediate frame draws out two slubbings to the thickness of one, again slightly twists it, and winds it on a bobbin. In the roving-frame the slubbing is drawn out further, slightly twisted, and wound on a bobbin. The rovings or bobbins of rove are then ready for the spinning-frame, which in the case of heavy stout yarns is invariably the throstle, but when fine counts are spun the spinning is done on the mule. In throstle-spinning the roving is attenuated by passing between rollers increasing in speed till the desired tenuity is attained, at which point the final twist is given, and the yarn is wound on the bobbin or pirn ready to receive it.

There are three methods of twisting practised in throstle-spinning. The first and oldest is with spindle, bobbin, and flyer, in principle precisely the same as the arrangement in the spinning-wheel. The second method is cop-spinning, in which the spindle is stationary, but the bobbin which revolves around it is caused at once to give the twist and wind the yarn on its own surface. This is effected by fitting over the bobbin a steel cop or cover of sufficient dimensions to cover a filled bobbin. The cop has a smooth steel edge which keeps the yarn free from the bobbin while the twist is being put on, and which by its motion up and down regulates the winding of the finished yarn on the bobbin. The third and most recent development of throstle spinning is the ring and traveller frame. In this both spindle and bobbin revolve together and give the twist; but the yarn passes to the bobbin through a traveller or eye of steel set on a flanged steel ring which encompasses the spindle and bobbin. The traveller keeps the yarn free from the bobbin while the twist is being put in, and being carried round by the bobbin it winds the yarn on the bobbin, the filling of which is regulated by an up-and-down motion communicated to the rail on which ring and traveller are fastened. In mule-spinning the bobbins of rove are mounted on a fixed frame, and corresponding yarn bobbins or paper cops are attached to the spindles, which are mounted on a carriage made to travel back and forward over a space of two yards or thereby. The spinning in this apparatus is intermittent. The drawing rollers at the fixed frame give out a certain length of roving; and simultaneously the carriage begins to move away, and the spindles rotating rapidly put twist on the rove. At a certain point the rollers cease to give off roving, but, the carriage still travelling backward and the spindles rotating, the yarn is further drawn out and correspondingly more twist is imparted. The twist becomes hardest at the points where the yarn is weakest, the drawing power of the carriage is exercised most on the thickest portions of the yarn, and thus twisting and drawing so compensate each other that yarn of great regularity is produced. When the carriage reaches its full stretch the yarn is completely spun, and in returning towards the frame the separate strands are lowered so that they are wound around the cops by their rotation. Then the operations are repeated, and go on doing to perhaps 200 strands of yarn by mechanical agency precisely the series of operations which for ages mankind with a single spindle did for a single strand of yarn—viz. drawing out, twisting, and ultimately winding up the finished yarn. Previous to the invention of the mule few spinners could make yarn of 200 hanks to the pound (the hank being always 840 yards). At the same time the natives of India were weaving yarn of numbers ranging between 300 and 400 (i.e. 400 hanks to the pound). Now, however, our manufacturers have reached such extraordinary perfection that Manchester spinners have made No. 700, which was woven by a French firm. No. 10,000, a pound of which would reach 4770 miles, has been made to test machinery.

Spinola, AMBROSIO, MARQUIS OF, one of the greatest captains of his time, was born at Genoa in 1571. With his younger brother Frederick, already a soldier of fortune under Philip III. of Spain, he raised in 1602 a force of 9000 men, whom he maintained, like the old *condottieri*, at his own expense. In the same year he entered the Netherlands, serving at first under Mendoza. His first exploit was the reduction of Ostend, which the Archduke Albert had been besieging for more than two years. This spread his reputation over Europe, and led to his being placed at the head of the whole Spanish and Italian troops in the Netherlands. Now began a long struggle with Prince Maurice of Nassau, in which neither could gain any decided advantage over the other. The destruction of the Spanish fleet near Gibraltar induced the court of Madrid to conclude in 1609 an armistice for twelve years. At its termination the war began anew, and Spinola found himself once more pitched against his great opponent, who, however, died before the walls of Breda of a marsh-fever caught during his attempts to raise the siege. The town opened its gates in the May of 1625, after having sustained a siege of ten months. This was Spinola's last achievement, his health now obliging him to resign the command. He had spent his whole fortune in the maintenance of his troops, but his pecuniary claims were shamefully neglected by the Spanish government, and his acute vexation at this hastened his death, which took place in Piedmont, 25th September 1630.

Spinoza, BENEDICT (*Benedictus* being a translation of the Hebrew *Baruch*), one of the greatest philosophers of modern times, was born at Amsterdam on the 24th of November 1632. His parents were rich Spanish or Portuguese Jews, whose name (also spelt D'Espinoza and Despinoza) seems to have been derived from a village called Espinoza in Leon. They had their son diligently instructed in the Bible and its commentaries, and the Talmud; but after having mastered both, and imbibed the philosophical spirit of such commentators as Aben Ezra, he was allowed—the more readily that his sickly constitution unfitted him for a commercial career—to devote himself entirely to a life of study. Physical sciences and the writings of Descartes, to which he turned first of all, very soon drew him away from the rigid belief and practices of the synagogue; and Saul Levi Morteira, his Talmudical teacher, who had built the fondest hopes upon the genius of his pupil, was the first to threaten him with the direst punishment if he did not retract the rank heresies that he began openly to utter. Spinoza, after a time, entirely withdrew from the community of his brethren, who formally excommunicated him (1656). A fanatic even attempted to frighten him by an either real or feigned attack upon him as he left the synagogue one night. At that period the young truth-seeker made the acquaintance of the young and beautiful daughter of Van den Ende, his master in Greek and Latin, and fell passionately in love with her, but was rejected. From that time forth Philosophy became the sole aim and object of his life. In accordance with the teachings of the sages of the Mishna, Spinoza had, apart from his studies, made himself master of a mechanical craft; he had learned the art of polishing lenses, and this now became the means of his subsistence.

When twenty-eight years old he left Amsterdam, and went to Rijnsburg, near Leyden, then the headquarters of a sect of the Remonstrants or Arminians, known as *Collegiants*, with one of whom he lived; and there he wrote the *Abridgment of the Meditations of Descartes*, with an Appendix—the latter being the first draft, so to say, of his *Ethics.* The year following he removed to Voorburg, a suburb of the Hague, and shortly afterwards, yielding to the solicitations of his, by this time, numerous friends, he removed to the Hague itself. The Elector Palatine, Charles Louis, next offered him a vacant chair at the university of Heidelberg, with full 'liberty of teaching,' provided he would not say aught to prejudice the established religion—i.e. Christianity; but Spinoza declined the lucrative and honourable professorship. His small pittance was enough to satisfy his wants. Similarly he refused generous offers made to him by wealthy friends, like Simon de Vries, who intended to bestow a large sum of money upon him; all he could be prevailed upon to accept was a small annuity of a few hundred florins. An offer of a pension, on the condition of his dedicating a work to Louis XIV., he rejected with scorn. His domestic accounts, found after his death, show that he preferred to live on a few pence a day rather than be indebted to another's bounty. He died, forty-four years old, on the 21st of February 1677. Throughout his life of study, of abstemiousness, of bodily and mental suffering—for his constitution was no less undermined by consumption and overwork than his sensitive mind was wrought upon by the violent severance of all natural ties of affection, to say nothing of the misery of occasional want and of perpetual persecution—no complaint ever passed his lips. Simplicity and heroic forbearance, coupled with an antique stoicism and a childlike, warm, sympathising heart, were the outstanding features of him who was nicknamed epicurean and atheist by his contemporaries.

Spinoza's philosophical system developed itself on the basis of Descartes (q.v.), who, dissatisfied with both the dogma and the scepticism around him, cleared the ground by first doubting everything, and then laying a new foundation in *Cogito, ergo sum.* Spinoza, however, took his 'I think, therefore I am' merely as a starting-point to establish not (as with Descartes) an unreconciled dualism of spirit and matter, but a pure Monism, of which the sole foundation is Substance—'that which is in itself and is conceived through itself;' with an infinite number of Attributes, of which thought and extension, or spirit and matter, are alone dealt with. Spinoza's one Substance, *causa sui,* he expressly calls God; yet this term is not to be understood in the ordinary sense, for Spinoza's God neither thinks nor creates. There is no real difference, he holds, between mind, as represented by God, and matter, as represented by Nature; they are One, and, according to the light under which they are viewed, may be called either God or Nature. The visible world is not distinct from him. It is only his visible manifestation, flowing out of him, who is the first fountain of life and essence, as a finite from the infinite, variety from unity—a unity, moreover, in which all varieties merge again. Extension and thought, which with Descartes had been two Substances, with Spinoza become Attributes—that which the mind perceives as constituting Substance. Extension is visible Thought; Thought is invisible Extension. And this explains the relation between body and mind, and the perfect harmony between them. The mind is the idea of the body—i.e. the same thing considered under the attribute of thought. Substance as thought falls into an infinite number of Ideas, and as extension into an infinite number of Bodies. These Spinoza calls Modes. The *modus* or *accidens* is only the varying form of Substance. Like the curling waves of the ocean, the modes have no independent existence; they are simply the ever-varying shapes of the Substance. Substance thus is the only really existing, all embracing essence, to which belongs every thing perceptible to our senses, and every thing not perceptible. Thus, every thought, wish, or feeling is a Mode of God's Attribute of thought; every thing visible is a Mode of God's Attribute of extension. God is the 'immanent idea,' the One and All, the *natura naturans*; World, *natura naturata*, is one complex whole and one peculiar aspect of God's infinite Attribute of extension. The variety we behold in things is a mere product of our faulty conceptions, particularly of what Spinoza terms our 'imagination,' which perceives unity as a complex of multiplicity. The connection of things is the same as the connection of ideas; we attain the truth only when, looking away from the multiplicity of ideas and of things, we behold God *sub specie æternitatis*.

His system is mainly contained in his *Ethica*, which is not a treatise of Ethics, but a complete philosophy. The *Ethica* he deduces in a mathematical form, after the method of Euclid, but with a stringency much more apparent than real. Chief doctrines are: The absence of free-will in man—himself only a *Modus* dependent on causes without, and not within him. Will and Liberty belong only to God, who is not limited by any other Substance. Good and Evil are relative notions, and sin is a mere negative; for nothing can be done against God's will, and there is no idea of Evil in him. Utility alone, in its highest sense, must determine the good and the evil in our mind. Good, or useful, is that which leads us to greater reality, which preserves and exalts our existence. Our real existence is knowledge. Highest knowledge is the knowledge of God. From this arises the highest delight of the spirit. Happiness is not the reward of virtue, but virtue itself; and this is to be attained by a diligent following in God's ways. Sin, evil, negation, &c. are merely things that retard and obstruct this supreme happiness. Spinoza's Pantheism was long regarded as 'the most iniquitous and blasphemous human invention,' and had few followers even in Holland. But in the 18th century it attracted the admiration of men such as Lessing, Herder, and Goethe, and became with Fichte, Schelling, and Hegel the acknowledged basis of much of modern German philosophy; and pious theologians like Schleiermacher did not hesitate to apply to Spinoza the epithet of 'pious, virtuous, God-intoxicated.'

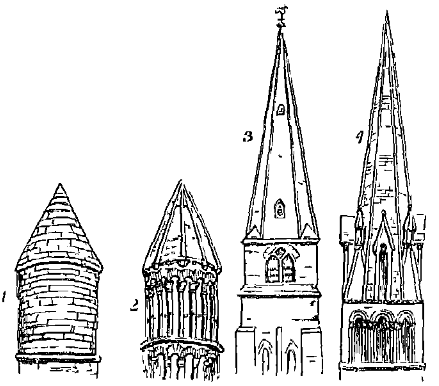
Spinoza's principal works are *Renati Descartes Principia Philosophiæ More Geometrico Demonstrata* (Amsterdam, 1663); *Tractatus Theologico-politicus* (anonymous, 1670); and, published as *Opera Posthuma*, in the year of Spinoza's death by Ludwig Meyer: *Ethica Ordine Geometrico Demonstrata* (written in its essentials in 1662 65), *Tractatus Politicus*, *Tractatus de Intellectus Emendatione*, *Epistolæ*, *Compendium Grammatices Linguæ Hebrææ*. Several minor treatises are lost; but the *Tractatus de Deo et Homine*, published in 1862, is a most valuable addition to our materials for tracing the development of Spinoza's system. The *Tractatus Theologico-politicus* contains an acute and rationalistic view of revelation, and in his biblical criticism Spinoza shows much more directly the influence of Maimonides than in his ethics. In his politics he has many *points common with Hobbes. The literature on the* Spinozistic philosophy is very copious, especially in Germany; Spinoza's life has even been made by Auerbach the subject of a romance. There are editions of Spinoza's works by Paulus (1803), Bruder (1846), and especially Van Vloten and Land (2 vols. 1882–83). There are translations of Spinoza's chief works by Elwes (1884), and of the *Ethic* by W. H. White (1883), as also by H. Smith (with an essay, *Spinoza and his Environment*, Cincinnati, 1886). There are English monographs on Spinoza by Sir F. Pollock (1880), Dr Martineau (1882), and Principal Caird (1888); works in German by Sigwart (1839), Thomas (1840), Camerer (1877), and Baltzer (1888); in French by Saintes (1842). See, besides Ueberweg and the other histories of philosophy, the bibliography by Van der Linde (Hague, 1871). A monument to Spinoza was erected at the Hague in 1880.

Spiræa, a genus of plants of the natural order Rosaceæ, and of the sub-order Spiræeæ, in which the fruit consists of five or fewer capsular carpels. The genus Spiræa has one or more follicular, many-seeded carpels. It contains a large number of species, natives of Europe, Asia, and America, herbaceous plants and low deciduous shrubs; of the herbaceous species two are natives of Britain, Dropwort (*S. filipendula*) and Meadow Sweet or Queen of the Meadow (*S. ulmaria*), both with interruptedly pinnate leaves and flowers in cymes. Dropwort is a native of dry upland pastures; it is tonic and fragrant; and its tubers, which are somewhat nutritious, are in Sweden ground and made into bread. Meadow Sweet is well known for the powerful fragrance of its flowers. A fragrant distilled water is prepared from them. A North American species (*S. tomentosa*), called Hardhack in the United States, is there used as a tonic and astringent. Many of the shrubby species are frequently planted for ornament.

Spiræa aruncus.

Spiral Vessels. See STEM.

Spire, a very acute pyramidal roof in common use over the towers of churches. The history of spires is somewhat obscure, but there is no doubt that the earliest examples of anything of the kind are the pyramidal roofs of the turrets of Norman date. Those of St Peter's, Oxford (fig. 1), and Rochester Cathedral (fig. 2) are good specimens of circular and octagonal pointed roofs, or spires in an *embryo condition. Spires of this early period* are much less acute than those of later date. The Early English style has spires of sharply pointed form over the larger towers. They are generally octagonal and what are termed broach spires—i.e. the slopes spring from the cornice of the tower without any parapet, and at the point where the square changes to the octagon there is a small set-off or separate roof (fig. 3). Sometimes the angles at top of towers were occupied with pinnacles or sloping masses of masonry, as at Bayeux *Cathedral, Normandy (fig. 4).*



1, Turret, St Peter's Church, Oxford; 2, Turret, Rochester Cathedral; 3, St Mary's Church, Cheltenham; 4, Bayeux Cathedral, Normandy.

In the Decorated style the spires were more ornamented, having generally *a parapet and* pinnacles at the top of the tower, crockets on the angles, and enriched windows. The spires of the Perpendicular and Flamboyant styles are still more enriched, with flying buttresses at the angles, &c. They are sometimes perforated, and the sides of the spire filled entirely with tracery. Such spires are common in Germany, those of Strasburg and Freiburg on the Rhine being very fine examples, *as also* that of St Stephen's, Vienna. As in the later styles generally, the character and beauty of the spire give *place to dexterity in* masonry, and many examples exist of traceried spires more wonderful than beautiful (see GOTHIC ARCHITECTURE). Spires are most frequently constructed of stone, but they are also occasionally made of wood, and covered with lead, copper, slates, or shingles. These are chiefly to be found in localities where stone is scarce. Among famous spires may be mentioned those of Ulm (530 feet), Cologne (q.v., 515), Rouen (of cast-iron, 487½), St Nicholas, Hamburg (482), Strasburg (465), Chartres (q.v., 371), *and Salisbury* (q.v., 404), the highest in England, as St Mary's Cathedral, Edinburgh (275), is the highest in *Scotland, and* St Patrick's Cathedral, New York (328), in America. With these heights may be compared the Eiffel Tower (985 feet), the Washington obelisk (555), the Forth Bridge (361), and the domes of St Peter's at Rome (330) and St Paul's in London (215).

Spires (Ger. *Speier*), the capital of the Bavarian Palatinate, stands on the left bank of the Rhine, 19 miles S. of Mannheim. The most noteworthy edifice is the Romanesque cathedral, built of red sandstone, which has had a very chequered history. Begun by Conrad II. in 1030 and finished in 1061, it suffered from fire in the 12th, 13th, and 16th centuries, and in 1689 was stripped to the bare walls and even set fire to by the French, who also exhumed and scattered the bones of eight emperors of Germany (from Conrad II. to Albert I.) who lay buried in its crypt. Reconstructed in 1782, it was again desecrated by the French in 1794, but was once *more rebuilt in* 1797–1822. The interior walls are covered with more than thirty large frescoes by Schrandolph; *statues of the eight* emperors by Fernkorn (1858) adorn the vestibule; and in front of the west façade is the ancient 'Domnapf,' or cathedral basin. The town itself was also demolished by the French in 1689, and having been rebuilt since that date has broad though irregular streets, but very few ancient buildings, except the gateway or clock-tower (*alta porta*), dating from before 1246, and a few fragments of the imperial palace (Retscher), in which several diets were held. There are a museum, picture-gallery, *botanical* garden, and library. Pop. 16,064. There is some industry in cloth, paper, tobacco, sugar, &c. *Spires was known* in Roman times as *Augusta Nemetum* and *Noviomagus*, but was known as *Spira* from the 7th century. Previous to that, however, it had experienced repeated disasters at the hands of the successive barbarian armies that swept westwards. The early emperors showed it considerable favour, and in the 13th century it became a free imperial city. Several imperial diets were held within its walls, especially *that of 1529, at* which the reformers first acquired the name of Protestants; and from 1513 *to 1689 it was the seat of the supreme law-court* of the empire. But the repeated devastations it endured in the Thirty Years' War *and from* the French (see above) ruined its prosperity. It was the capital of a department of France between 1801 and 1814, and in 1815 passed to Bavaria. See works by Remling (1858-61), Weiss (1877), and Hilgard (1885).

Spirifer, a polyzoon of the Carboniferous System (q.v.).

Spirit, a name of very general application to fluids, mostly of a lighter specific character than water, and obtained by distillation. Thus, the essential oil of turpentine is called Spirit of Turpentine; a looser usage extended the name to Spirit of Nitre (nitric acid) and Spirit of Salt (hydrochloric acid). But in a stricter sense the term spirit is *understood to mean* Alcohol (q.v.) in its potable condition, of which there are very numerous varieties, *deriving their special characters from* the substances used in their production.

Spirit, HOLY, or HOLY GHOST, the third Person of the Trinity. The doctrine of the Spirit follows *and depends on that of the Son in Scripture* and in the development of dogma. It is significant for the whole subject that *ruach* and *pneuma,* Hebrew and Greek for spirit, literally mean 'wind' or 'breath.'

In the Old Testament 'the Spirit of God' is first the principle of life in creation (Gen. i. 2), in particular of man's life (ii. 7). Then to the Spirit are traced the special gifts, intellectual and even bodily, of the instruments of the theocracy, as Moses, Bezalel, Samson, and above all the prophets, who are the men of the Spirit. *At length in the* later writings—e.g. Ps. li. 11, cxliii. 10—the Spirit is called 'holy' *and* 'good,' and the agency comes to be spoken of chiefly as moral. But there is nothing at all decisive as to personality, and the action is temporary and external, and is not general except in predictions of the period to be introduced by the spirit-anointed Servant of the Lord, when the Spirit is to be poured out on all (Joel, ii. 28).

In the New Testament the Spirit is throughout 'the Holy Spirit,' and is now also the 'Spirit of Christ,' the doctrine being conditioned by the two great facts, the coming of Christ, and His return to the Father. The Synoptists deal almost exclusively with the Spirit's influence on Christ Himself, especially in the miraculous conception of His humanity, and in the descent at His baptism, by which He is equipped for His office. But the fulfilment of the predicted baptism by Christ with the Holy Spirit (Matt. iii. 16, &c.; cf. Joel, ii. 28) is found in the Acts in the outpouring of the Spirit at Pentecost, and subsequently, by which not only the apostles, but disciples generally, are endowed with 'tongues' and other miraculous gifts of witness-bearing to Christ. All this, and the similar teaching of Peter and the author of the Hebrews, still runs largely on Old Testament lines. But in Paul and John, along with these representations, distinct developments are found. All the epistles of Paul contain his characteristic doctrine of the Spirit as the principle of the new life, in its beginning and progress. As such, the Spirit is the witness of sonship, the ground of fellowship with Christ, and of every Christian grace, and the earnest of complete salvation. Those so consecrated form the church, the temple of God, the body of Christ. John touches on Paul's view (John, iii. 5). But his special contribution is the farewell words of Christ (xiv. 16, 17, 26; xv. 26; xvi. 7-14), where the Spirit as the Paraclete (Advocate or Comforter) is first expressly presented as a person, proceeding from the Father, and to be sent after Christ's departure, that as the Spirit of truth He may confirm and complete the revelation already given in the Son. Thus, while the personality is implied in the baptismal formula (Matt. xxviii. 19) and the apostolic benediction (2 Cor. xiii. 14, and other passages), it comes clearly out only in the 'He' of this latest writer of the New Testament.

After apostolic times the church's faith in the Spirit was for long simply that of the baptismal formula held without dogmatic definition. Montanism, with its conception of the Spirit as still operating in the manner of the apostolic age, called attention to the subject. But it was as complementary to the doctrine of the person of Christ, the starting-point of the Trinitarian dogma, that the Spirit doctrine was elaborated, at first incidentally, then directly. The reply to the Gnostic emanation theories, and to the Sabellian view of the Trinity as merely modes of God's manifestation, helped to draw out the church's mind on the Spirit's essential deity and personality, though, in distinguishing the persons, Origen and others unduly subordinated the Son, and especially the Spirit. The doctrine was directly handled after the middle of the 4th century, when Arianism, which carried this subordination to the extreme in denying the deity of the Son, was explicitly extended to the Spirit by Eunomius, and diverted thereto by the Semi-Arians, hence called Pneumatomachi. Against their view that the Spirit is only a creature Athanasius and others brought the consubstantiality of the Spirit into line with that of the Son, and in 381 the Council of Constantinople added to the bare Nicene profession of faith in the Holy Spirit—'the Lord, and giver of life, who proceedeth from the Father, who with the Father and Son together is worshipped and glorified, who spake by the prophets.' From that day to this almost all the divergencies from the church doctrine of the person have been of the Sabellian order. It remained to define the essential relation of the Spirit to the Son. Western theology tended to emphasise the unity of essence in the Trinity, Eastern the Father as the fountain of godhead. Accordingly the doctrine of the Spirit's eternal procession from the Father and the Son (*Filioque*), fully developed by Augustine, rooted itself in the West, while in the East the procession was held to be from the Father only, or from the Father through the Son. At or before the Synod of Toledo in 589 the *Filioque* was inserted in the Creed of Constantinople, and this interpolation became one of the main causes of the schism between East and West. The churches of the Reformation accepted the procession from the Son, which as recently as 1875 was discussed at the Bonn conference between Easterns, Anglicans, and Old Catholics. But Protestantism was long naturally occupied rather with the Spirit's work. From strong interest in the latter peculiar views have sometimes emerged, not least in the religious movements of the 19th century, which has seen Montanism revived in Irvingitism.

The dogmatics of the Spirit, in its two divisions of the person and the work, encounters the two great problems of theology. In exhibiting the Spirit's work in conviction, regeneration, and sanctification, and also in inspiration, the relation of the Spirit's activity to man's falls to be determined. See CALVIN, ARMINIUS, JANSEN, WILL, and INSPIRATION. All progressive dogmatics not rationalistic addresses itself more and more to a thorough-going recognition of both factors. As for the Trinitarian problem, which has come again to the front, a stricter biblical theology has somewhat narrowed the basis of dogmatics, so far as the Scripture evidence of the Spirit's personality is concerned. And it is now more clearly recognised that not the ontological or essential, but the economic, Trinity—i.e. the Trinity in relation to man—is presented in Scripture, even the 'proceedeth' of John, xv. 26, being understood as temporal, not eternal. All the more does theology feel called upon to rise to the ontological Trinity, and labours, especially in Germany, to deduce it from the idea of the Divine self-consciousness, the Divine love, &c. Philosophy itself takes similar paths. Many, however, who call themselves Trinitarian are so only in a pantheistic or Sabellian sense, and regard the Spirit as merely a divine energy, or, with Schleiermacher, as God operative in the church.

Literature.—(1) Patristic: Athanasius, *Epistolæ ad Serapionem*; Didymus Alex., Basil the Great, and Ambrose, *De Spiritu Sancto*; Gregory Nazianzen, *Orationes de Theologia*, v.; Augustine, *De Trinitate*, iv. v. xv., *Tractatus in S. Joannem*, and *Contra Maximinum*. (2) Modern: Owen, *Pneumatologia* (1674), still, though prolix, the profoundest of the numerous English works; Heber, *Personality and Office of the Comforter* (Bampton Lectures, 1816); Burton, *Testimonies of the Anti-Nicene Fathers to the Divinity of the Holy Ghost* (Works, vol. ii. 1831); Hare, *Mission of the Comforter* (1846; 4th ed. 1877); Kahnis, *Die Lehre vom Heiligen Geiste* (Halle, 1847—historical); Cardinal Manning, *Temporal Mission of the Holy Ghost* (1865) and *Internal Mission of the Holy Ghost* (1877); Swete, *Early History of the Doctrine of the Holy Spirit* (Camb. 1873) and *History of the Doctrine of the Procession* (1876); Smeaton, *Doctrine of the Holy Spirit* (Cunningham Lectures, 1882). For the different departments of the subject reference should also be made to the standard works on biblical theology, the history of doctrines, and dogmatics. See also the articles CHRIST, TRINITY.

Spirit-fresco. See MURAL DECORATION.

Spirit-level. See LEVELLING.

Spiritualism (on the Continent usually termed Spiritism) is the name applied to a great and varied series of abnormal or preter-normal phenomena purporting to be for the most part caused by spiritual beings, together with the belief thence arising of the intercommunion of the living and

Copyright 1892 in U.S. by J. B. Lippincott Company.

the so-called dead. The following is a definition given in the London *Spiritual Magazine*, for many years the best exponent of the subject in Great Britain: 'Spiritualism is a science based solely on facts; it is neither speculative nor fanciful. On facts and facts alone, open to the whole world through an extensive and probably unlimited system of mediumship, it builds up a substantial psychology on the ground of strictest logical induction. Its cardinal truth, imperishably established on the experiments and experiences of millions of sane men and women, of all countries and creeds, is that of a world of spirits, and the continuity of the existence of the individual spirit through the momentary eclipse of death; as it disappears on earth reappearing in that spiritual world, and becoming an inhabitant amid the ever-augmenting population of the spiritual universe.'

The movement known as 'modern spiritualism' is usually considered to have commenced in the year 1848, with certain mysterious noises and movements occurring in a house temporarily occupied by Mr Fox and family at Hydeville in the state of New York; and his two daughters, Margaret and Kate, aged twelve and nine years respectively, were the first individuals recognised as mediums, in whose presence the phenomena more particularly occurred. It must not be supposed that the phenomena themselves were at all new. Throughout all history there are records of similar occurrences. Such were the disturbances at the ancient palace of Woodstock in 1649; at Mr Mompesson's at Tedworth in 1661; at Epworth parsonage in 1716, in the family of Mr Wesley, the father of the founder of Methodism; the Cock Lane ghost in London investigated by Dr Johnson, Bishop Percy, and other gentlemen; the extraordinary occurrences in the house of Mr Jobson in Sunderland in 1839, which were investigated and published by Dr Clanny, F.R.S., and authenticated by sixteen witnesses, including five physicians and surgeons; and numerous less important cases recorded in the works of William Howitt, Robert Dale Owen, Dr Eugene Crowell, and many older writers. But none of these occurrences attracted much attention or led to any systematic investigation of the subject. What especially distinguishes the year 1848 is that it was the starting-point of a movement which has grown and spread continuously, till, in spite of ridicule, misrepresentation, and persecution, it has gained converts in every grade of society and in every civilised portion of the globe. Spiritualism is now to be found as frequently among the highest aristocracy as among the middle classes and the poor. It has its full proportion of believers in the foremost ranks of science, literature, and art, and in all the learned professions. In every European country, in America, and in Australia there are numerous periodicals which diffuse a knowledge of its phenomena, its teachings, and its philosophy; while it claims to have profoundly modified the teaching of some among our clergy as to the nature and purpose of the future life. These facts and characteristics broadly distinguish modern spiritualism as being very different from anything that has preceded it, and claim for it a respectful consideration.

When the knockings and movements of furniture were first heard and seen they were assumed to be due to some trick or other natural cause, and there was in every case and throughout the whole course of the movement a strong prejudice against any other explanation of them. When the Fox family could not detect this cause the neighbours were called in, but equally without result. It was soon observed that the more violent sounds or motions occurred in the presence or in the immediate vicinity of one or other of the little girls, and every precaution was taken against possible trick on their part. They were closely watched, were held hand and foot, were tied in bags or put to stand barefooted on pillows, but all in vain. The raps or loud knockings on doors or tables, on floor or ceiling, occurred just the same. But this was only a part of the phenomena. It was observed that the noises occurred at request, or as if in reply to observations. Then the alphabet was used, and questions were answered by raps at certain letters which, when written down, formed connected words and sentences. In this way the statement was elicited that the sounds were made by the spirit of a man who had been murdered in the house and buried in the cellar. After several explorations human bones with charcoal and lime were discovered there. Some confirmatory evidence as to this murder was obtained, and some of the previous dwellers in the house stated that they also had been disturbed by unaccountable noises. The excitement caused by these occurrences was so great that in order to satisfy the curiosity of visitors the Fox family were obliged to submit to public exhibitions and tests of the remarkable phenomena occurring in the presence of their children, and thus public mediumship began. But at the same time other mediums were discovered in different parts of the country, as if a special development of this abnormal power were then occurring. A few of the more remarkable of these mediums may be here briefly referred to.

In 1845 an altogether illiterate youth, Andrew Jackson Davis, the son of a poor weaver and apprenticed to a shoemaker at Poughkeepsie, New York, began to exhibit remarkable powers as a trance speaker and a clairvoyant healer of diseases. During his trances he exhibited such extensive knowledge of subjects quite beyond his waking abilities or acquirements as to attract the attention of learned men, and under their auspices he delivered in New York 157 lectures which were afterwards published in a volume of 800 pages. These powers have continued to be exerted during a long life. One of his disciples was Thomas Lake Harris (q.v.), whose *Lyric of the Golden Age*, a poem of 384 pages, was dictated in ninety-four hours, and in the opinion of William Howitt deserves the praise that has been given it of possessing almost Miltonic grandeur. Just about the same time (1846-50) the Davenport brothers began to exhibit the remarkable physical phenomena that puzzled so many observers in every part of the world; and it was about the year 1846 that the celebrated medium Home, then thirteen years old, had his first vision of a boy friend, 300 miles away, who intimated to him that he had died three days before at a certain hour, which was afterwards found to be perfectly correct.

Nature and Range of the Phenomena.—In almost every case the medium is a person who in youth sees visions and hears voices which often communicate intelligence of distant and sometimes future events quite unknown to himself or family. Following such phenomena, and apparently to attract the attention of other persons, noises usually occur; sometimes voices are heard, and sometimes musical sounds. Then follow movements of material objects, either visibly or more often in the dark, or in such a way that the result only is seen. Rooms and even houses are sometimes shaken; bells sometimes ring violently without material cause; flowers, fruits, or other objects are brought from a distance into closed rooms, sometimes of particular kinds as desired at the moment by those present. Another curious phenomenon is the tying and untying of knots. Sometimes the medium is tied in such a manner that it is plainly impossible he could have so tied himself; sometimes when tied by other persons, and the knots and ends of the cords out of his reach, he is almost instantaneously released. Knots are sometimes tied on endless cords in a manner impossible by human agency, as in the experiments of Professor Zollner.

A frequent phenomenon is the playing on musical instruments without human agency, as on an accordion held by the medium by one hand, and sometimes when held by spectators. Closed pianos are sometimes played on, while accordions or tambourines are, as it were, floated in the air and played upon at the same time.

Writing or drawing is often performed without human agency. Sometimes the writing occurs on papers held or thrown under the table, or when placed in locked drawers, or enclosed between slates tied or screwed together. Sometimes the writing thus obtained is in answer to questions which may be spoken or written, and either known or unknown to the medium. The drawings are of various kinds. Some are on slates with pencil or chalks, some on paper. Very effective drawings in crayons, water-colours, or oils are produced with extreme rapidity and under conditions which render normal human agency impossible. A Scottish medium was accustomed to produce small landscapes in oils on cards privately marked by the witnesses and in total darkness, the result being seen with the paints still wet. These were usually effective and artistic works. In another case the space under a table was enclosed by a large shawl hanging to the ground. Marked cards were thrown underneath, and in from ten to fifteen seconds the drawings were complete. A number of these drawings were in the possession of the late Mr Benjamin Coleman, and were shown to the present writer. One in particular was on paper marked by Mr Coleman with two pin-holes by pins which were stuck through a small strip of paper which was kept as a proof of the identity of the paper so marked. The drawing that was made on this paper consisted of two birds holding a garland of flowers in their bills, and was so executed that the two pin-holes which had been made on the paper formed the eyes of the two birds, while their exact correspondence with the strip kept with the pins in it showed that the very paper Mr Coleman had so marked had been used. Lord Borthwick was present when these drawings were described, and confirmed Mr Coleman's account of them before the committee of the Dialectical Society in 1869.

One of the most striking of the physical phenomena is the levitation of the human body, which has occurred with many mediums, but has never been more thoroughly tested than with the late Mr Home. The extraordinary elongation of his body was also tested by many competent observers; while in his presence, as in that of some other mediums, heavy tables were often raised to a considerable height, or inclined at an angle of nearly 45°, without the numerous objects on the table, as books, glasses, lamps, &c., falling off.

A very marvellous phenomenon exhibited by Mr Home, and a very few other mediums, is the power of neutralising the action of fire, both in their own persons and in that of some of the spectators. Lord Lindsay (since 1880 Earl of Crawford) made the following statement before the Dialectical Society: 'I have frequently seen Home when in a trance go to the fire and take out large red-hot coals and carry them about in his hands, put them inside his shirt, &c. Eight times I have myself held a red-hot coal in my hands without injury, when it scorched my face on raising my hand. . . . A few weeks ago I was at a séance with eight others. Of these seven held a red-hot coal without pain, and the two others could not bear the approach of it.' Lord Adare, Mr Jencken, and several others saw Mr Home stir the fire with his hands and then put his face right among the burning coals, moving it about as though bathing it in water. Mrs S. C. Hall, the Earl of Crawford, and several others saw Mr Home place a large lump of burning coal on Mr S. C. Hall's head and draw up his white hair over the red coal. It remained there several minutes. After it was taken away it burned the fingers of some who attempted to touch it. A number of other persons of the highest character have testified to similar occurrences with Mr Home.

Even more extraordinary, and still more remote from the normal powers of mankind, is the production of visible and tangible hands—which lift objects, and sometimes write, and then dissolve away—of faces, and even of entire figures, all under conditions which render imposture impossible. Both visible and invisible phantoms have had their objectivity proved by being photographed, and this has been done by experts who are above suspicion and under conditions which render the reality of the phenomena demonstrable. Both hands, feet, and faces of these phantom forms have produced moulds in melted paraffin, again under conditions which render imposture on the part of the mediums out of the question.

Yet another and final series of phenomena, which may be termed psychological or spiritual, are the seeing of spirits or spiritual forms invisible to others, hearing their voices, and by this means obtaining knowledge of circumstances occurring at a distance; or of facts unknown to any one present, but afterwards verified; or of future events which afterwards happen as predicted—of all of which there is ample evidence. Persons gifted with this power often give long and eloquent addresses, or have elaborate essays written through their hands, but without any conscious mental agency on their part; and it is from these communications that we acquire our most complete knowledge of the teaching and philosophy of modern spiritualism.

Some Characteristics of Mediums.—These numerous distinct classes of phenomena exhibit endless modifications in detail with different mediums, and there are several important considerations which are inconsistent with their being, to any considerable extent, due to imposture. In the first place, almost every medium exhibits his powers in youth or even in childhood without any opportunity of learning the methods employed by professional conjurers. In the second place, each medium exhibits considerable individuality, and rarely, perhaps never, offers an exact reproduction of the phenomena occurring with other mediums. In the third place, all the phenomena occur sometimes in private houses, to which the medium comes without any apparatus whatever. In the fourth place, every class of phenomena has occurred with unpaid mediums, as well as with those who make mediumship a profession. And lastly, many of the most remarkable mediums have submitted to elaborate and careful tests by scientific and intelligent observers with results wholly beyond the powers of professional conjurers.

Notable Investigators of the Phenomena.—In order to appreciate the important bearing of such investigations on the theory that the whole body of spiritualistic phenomena are due to delusion or imposture, a few of the best known of these inquirers must be referred to. Perhaps the earliest scientific investigator was Dr Robert Hare (*q.v.*) of Philadelphia, an eminent chemist, especially known for his invention of ingenious apparatus. He, like all other earnest and patient inquirers, began under the impression that he would be able to expose a delusion; but all his experiments and tests, with apparatus of his own devising, proved that he had to deal with a great reality. He accordingly tried to induce the legislature to appoint a committee to examine and report on the experiments, and failing to succeed in this published his results in a volume entitled *Experimental Examination of the Spiritual Manifestations.*

Judge Edmonds, one of the most acute and painstaking of American lawyers, devoted years to a thorough examination of the phenomena, with the assistance of the most intelligent men of science and education among his acquaintance. He himself became a medium, as did his daughter; and this young lady, though possessing only the ordinary American school acquirements, was able when in a trance to speak many foreign languages, including modern Greek, and to hold conversations in them with natives.

Professors Mapes and Loomis, both chemists, assisted by two physicians and other friends, tested the Davenport brothers, and found that the phenomena occurring with them were in no way due to conjuring. This verdict was confirmed by many inquirers in England, among others by the late Sir Richard Burton, the last man to be imposed upon by conjuring, and to endorse it as reality. Yet he says, in a published letter, 'I have now witnessed four of the so-called dark séances. These were all in private houses—one of them in my own lodgings. We rejected all believers, and chose the most sceptical and hard-headed of our friends and acquaintances, some of whom had prepared the severest tests. We provided carefully against all possibility of confederates, and brought our own cords, sealing-wax, tape, diachylon, musical instruments, and so forth. . . . Sparks of red and pale fire have fallen from the ceiling, sometimes perpendicularly, at other times crossing the room. Mr Fay's coat was removed whilst he was securely fastened hand and foot, and a lucifer match was struck at the same instant showing us the two gentlemen fast bound and the coat in the air on its way to the other end of the room. . . . I have spent a great part of my life in oriental lands, and have seen there many magicians. . . . I have read and listened to every explanation of the Davenport "tricks" hitherto placed before the public, and if anything would make me take that tremendous leap "from matter to spirit," it is the utter and complete unreason of the reasons by which the manifestations are explained.'

Among other investigators of known integrity and ability are Robert Dale Owen and Dr Robert Chambers, who investigated the phenomena with Kate Fox in New York, while the latter was the friend of Home, and wrote for him the introductory chapter and the appendix to his *Incidents of my Life.* Dr George Sexton, an earnest secularist teacher and lecturer, was converted by phenomena occurring in his own house and through mediums who were members of his own family or personal friends; and he afterwards investigated the materialisation phenomena occurring through Miss Cook. Mr Cromwell Varley, the electrician, tested the same phenomena by means of electrical apparatus. Dr Lockhart Robinson, after a long experience in the treatment of the insane, and having been a violent opponent of spiritualism as wholly founded on imposture and delusion, was converted by phenomena occurring in his own house in the presence of the American medium Squire. Professor Zöllner of Leipzig, in his work *Transcendental Physics,* has described the most marvellous phenomena occurring in his own study and under the strictest test conditions, in the presence of the medium Slade with some of his fellow-professors as witnesses. And lastly, we have Mr William Crookes, one of the first chemists and physicists in Europe, who for several years (from 1870 to 1874) devoted a considerable portion of his time to the investigation of the phenomena, and had the courage to make public these experiments and their results. With several different mediums, in his own house and subject to the conditions of scientific experiment, he satisfied himself of the reality of the whole range of the phenomena here briefly described. So recently as 1889 he has published his notes of several séances with Mr Home, in the introductory observations to which he makes this important statement: 'Their publication will at any rate show that I have not changed my mind; that on dispassionate review of statements put forth by me nearly twenty years ago I find nothing to retract or to alter. I have discovered no flaw in the experiments then made, or in the reasoning I based upon them.'

The Value of these Phenomena.—In view of this long series of investigations by men of special training in science and of the highest reputation, spiritualists urge that the facts on which their beliefs are based are proved to be realities beyond all reasonable doubt. It may be asked, however, as many do ask, what is the meaning or the use of these strange phenomena? We feel no interest in moving furniture, floating bodies, fire-tests, or slate-writing. The answer is that to a very large number of minds these physical phenomena, however low and trivial they may seem, are the most effectual and often the only means of compelling attention to the subject, and this is more particularly the case with those imbued with the teachings of modern science. The moment such persons are really convinced that physical phenomena occur which they have always held and declared to be impossible, they see that there is something more in the matter than imposture or delusion, and further inquiry shows them that this class of facts constitute the mere outskirts of the subject. Almost all the agnostics and students of physical science who have become spiritualists—and they are to be counted by hundreds in every civilised country—have begun the investigation because they have been convinced that some of these lower physical phenomena are realities; and this fact is a complete answer to those who urge that such phenomena are trivial, degrading, and unspiritual. If they are so, it shows that men of the highest education and greatest knowledge are attracted by these very qualities.

The Teaching and Philosophy of Spiritualism.—But whenever we pass beyond these phenomena, and carefully examine the teachings and the philosophy to be found in the deliverances of automatic writers and trance-speakers, as well as in the normal writings of those who have long accepted and thoroughly assimilated these teachings, we enter upon a phase of the subject which no unprejudiced person will pronounce to be either useless or commonplace. The universal teaching of modern spiritualism is that the world and the whole material universe exist for the purpose of developing spiritual beings—that death is simply a transition from material existence to the first grade of spirit-life—and that our happiness and the degree of our progress will be wholly dependent upon the use we have made of our faculties and opportunities here. It is urged that the present life will assume a new value and interest when men are brought up not merely in the vacillating and questionable *belief,* but in the settled, indubitable *conviction,* that our existence in this world is really but one of the stages in an endless career, and that the thoughts we think and the deeds we do here will certainly affect our condition and the very form and organic expression of our personality hereafter.

As an example of the teaching of modern spiritualism as actually given through one of the most intelligent spiritualists and most trustworthy mediums, the following short passages from *Spirit Teachings*, by M.A., Oxon., must here suffice: 'As the soul lives in the earth-life, so it goes to the spirit-life. Its tastes, its predilections, its habits, its antipathies, they are with it still. It is not changed save in the accident of being freed from the body. The soul that on earth has been low in taste and impure in habit does not change its nature by passing from the earth-sphere any more than the soul that has been truthful, pure, and progressive becomes base and bad by death. . . . The soul's character has been a daily, hourly growth. It has not been an overlaying of the soul with that which can be thrown off; rather it has been a weaving into the nature of the spirit that which becomes part of itself, identified with its nature, inseparable from its character. It is no more possible that that character should be undone, save by the slow process of obliteration, than that a woven fabric should be rudely cut and the threads remain intact. Nay more; the soul has cultivated habits that have become so engrained as to be essential parts of its individuality. The spirit that has yielded to the lusts of a sensual body becomes in the end their slave. It would not be happy in the midst of purity and refinement. It would sigh for its old haunts and habits. They are of its essence' (p. 13).

'Immutable laws govern the results of deeds. Deeds of good advance the spirit, whilst deeds of evil degrade and retard it. Happiness is found in progress, and in gradual assimilation to the God-like and perfect. The spirit of divine love animates the acts, and in mutual blessing the spirits find their happiness. For them there is no craving for sluggish idleness, no cessation of desire for progressive advancement in knowledge. Human passions and human needs and wishes are gone with the body, and the spirit lives a life of purity, progress, and love. Such is its heaven. We know of no hell save that within the soul: a hell which is fed by the flame of unpurified and untamed lust and passion, which is kept alive by remorse and agony of sorrow, which is fraught with the pangs that spring unbidden from the results of past misdeeds; and from which the only escape lies in retracing the steps and in cultivating the qualities which bear fruit in love and knowledge of God' (p. 77).

'We may sum up man's highest duty as a spiritual entity in the word Progress—in knowledge of himself, and of all that makes for spiritual development. The duty of man considered as an intellectual being, possessed of mind and intelligence, is summed up in the word Culture in all its infinite ramifications, not in one direction only, but in all; not for earthly aims alone, but for the grand purpose of developing the faculties which are to be perpetuated in endless development. Man's duty to himself as a spirit incarnated in a body of flesh is Purity in thought, word, and act. In these three words, Progress, Culture, Purity, we roughly sum up man's duty to himself as a spiritual, an intellectual, and a corporeal being' (p. 154).

The following works have been consulted in writing this article: *The History of the Supernatural*, by William Howitt (2 vols.); *Footfalls on the Boundary of Another World* and *The Debatable Land between this World and the Next*, by Robert Dale Owen; *Planchette, or the Despair of Science* and *The Proof Palpable of Immortality*, by Epes Sargent; *Report on Spiritualism of the Committee of the London Dialectical Society; Primitive Christianity and Modern Spiritualism*, by Eugene Crowell, M.D.; *Researches in the Phenomena of Spiritualism*, by William Crookes, F.R.S.; *Miracles and Modern Spiritualism*, by the present writer; *Transcendental Physics*, by Professor Zöllner (trans. by C. C. Massey); *Spirit Teachings*, published by M.A., Oxon.; *D. D. Home: his Life and Mission*, by Mme. Douglas Home; and a review of this work by Professor W. F. Barrett and F. W. H. Myers, in the *Journal of the Society for Psychical Research*, July 1889.

Spitalfields, a poor district of north-east London, in the Tower Hamlets, derives its name from the *hospital* of St Mary, founded there in 1197 by Walter Brune and his wife Rosia. The manufacture of silk was established in Spitalfields by emigrants from France after the revocation of the Edict of Nantes (1685).

Spithead, a celebrated roadstead on the south coast of England, and a favourite rendezvous of the British navy, is the eastern division—the Solent (q.v.) being the western—of the strait that separates the Isle of Wight from the mainland. It is protected from all winds, except those from the south-east, and its noted security warranted the name which has been applied to it by sailors of the 'king's bedchamber.' It receives its name from the 'Spit,' a sandbank stretching south from the Hampshire shore for 3 miles; and it is 14 miles long by about 4 miles in average breadth. Here in 1797 the sailors of the Channel Fleet mutinied for more liberal pay and allowances, which were granted to them. Spithead has been strongly defended since 1864 by fortifications completing those of Portsmouth (q.v.).

Spitz or **Pomeranian Dog**, the result of a cross from the Esquimaux dog, the native dog of the Arctic regions. The spitz is about the size of the spaniel, with a sharp-pointed face and an abundant white coat sometimes of great beauty. Other colours are known, including black. As the spitz is useful for no kind of work, and is generally bad-tempered, this breed is rarely seen in England. It is comparatively common in the United States, where it is a favourite dog with Germans especially, and where many of the deaths in the hot months from hydrophobia have been due to its bite.

Spitzbergen, a group of Arctic islands, lying 400 miles N. of Norway, and consisting of West Spitzbergen (15,260 sq. m.), North-east Land (4040 sq. m.), Stans Foreland (2210 sq. m.), the three islands called King Charles Land or Wiche Island (also identified with Gillis Land), Barents Land, Prince Charles Foreland, and several smaller islands and clusters of islets. The whole is ice-bound, and there are magnificent glaciers on the eastern shores, especially on North-east Land, where Dickson's glacier has a length of more than 150 miles. A thick ice-sheet covers the whole of the interior of the larger islands; but several sharp peaks—whence the name Spitz ('needle-like') -bergen ('mountains')—project above it. These peaks are generally close upon 2000 feet in altitude; but one at least, Hornsund Tind, at the southern extremity of West Spitzbergen, reaches 4560 feet, and on the small island of Prince Charles Foreland, lying to the west of West Spitzbergen, there are peaks nearly 5000 feet in height. The shores of West Spitzbergen, except on the east, are deeply indented with fjords; two, Ice Fjord, stretching north-east and north, and Wiide Bay, coming southwards, almost meet and cut the island in two. The north-west shores of North-east Land are also very much broken. The eastern shores generally are difficult of access, owing to their being swept by a cold Arctic current from the north. But the Gulf Stream sweeps up along the west side of the group, and very considerably modifies the climate. The mean yearly climate seems to vary from 10° to 16° F. in different years. The vegetation, which was wonderfully luxuriant in the Miocene period, is now very scanty; except for the polar willow and a couple of berry-bushes, it consists principally of saxifrages and mosses. These last attract large herds of reindeer for the summer. Their ears are curiously marked, but where they come from is a mystery. The arctic fox and polar bear are the only other land animals that frequent the islands, though there are vast swarms of sea-fowl of various kinds (gulls, petrels, the eider-duck, wild geese, rotches, the snow-bunting, and others), several of which make these islands their breeding-quarters. The sea-waters round the coasts are exceptionally rich in marine fauna. During the 16th and 17th centuries large fleets of whalers from the North Sea countries and from Russia used to make these islands their head-quarters during the summer. But the whales have been almost exterminated, and the seals are rapidly approaching the same condition owing to reckless slaughter. The only frequenters of the group now are Norwegian walrus hunters and Swedish scientific explorers, who since 1858 have been unwearied in their efforts to obtain full information about the islands of the archipelago. There are no permanent inhabitants; but at times hardy Russian and Norwegian hunters have stayed one and occasionally more winters on the group. The Spitzbergen islands were discovered by Barents in 1596. They have on more than one occasion been made the starting-point of attempts to reach the North Pole. Here in 1861 and 1864 Nordenskiöld measured an arc of meridian.

See Lord Dufferin's *Letters from High Latitudes* (1857); Kropotkine's paper in *Ency. Brit.*, where ample sources are quoted; and *Scot. Geog. Mag.* (1889).

Spleen. This organ, present in vertebrates from the fishes upwards, has no doubt very important functions to perform, but about these we know as yet very little indeed. It is of the size and shape of a rather long halfpenny bun, and is situated in the left hypochondriac region, clasping by its flat surface the cardiac portion of the stomach (see figure at article ABDOMEN). Unlike the liver and pancreas, it has no duct and manufactures no juice, being connected with the rest of the body by its blood-vessels, nerves, and lymphatics: these enter the organ at its hylus and ramify within it. The spleen is invested by a capsule consisting chiefly of muscular tissue, and from this capsule muscular processes called trabeculæ run into the interior of the organ supporting its delicate pulp. As one would expect from its structure, the organ can expand and contract, and this it does from a variety of causes—for instance, after a meal the organ expands, reaching its maximum in about five hours, then contracting again. In diseased conditions it may expand to several times its normal size, which would not be possible were its capsule of fibrous tissue like those of other glands. The blood-vessels enter the spleen, and the arteries become invested by curious masses of tissue called adenoid, and these little masses, the splenic corpuscles, are of about the size of millet seed, and quite visible to the naked eye on cutting open the organ.

If the spleen of a man or an ox be cut open it will appear of a soft pulpy consistence and deep crimson in colour, with little white patches, these splenic corpuscles, scattered through it. On putting the spleen under a running jet of water the soft spleen pulp infiltrated with blood will be washed away, leaving behind the tough capsule, the branching trabeculæ, and the blood-vessels with some of these splenic corpuscles attached to them. The blood-vessels end in the tissue of the spleen, and those that terminate within the splenic bodies do so in the usual way, passing into true capillaries. Within the spleen pulp, however, which forms the chief part of the organ, the arteries open directly into the loose tissue forming the pulp, so that the blood percolates through this before leaving the organ by the veins. The blood thus becomes intimately associated with this pulpy tissue, and becomes modified by it, as we shall see. It is highly probable that the chief use of the spleen is to modify the blood passing through it, and hence it is spoken of as a blood-gland, in contradistinction to a digestive gland, which pours its secretion into the digestive tract, and aids the processes which go on there. It is very probable that the spleen has the power of arresting and destroying the old worn-out red blood-corpuscles as they pass through it, for within the spleen itself evidence of their destruction is found in the large quantity ever present of iron and other bodies, which would result from their dissolution. Moreover there is strong reason for supposing that the active agents in this destruction are the cells present in the spleen pulp, some of which are generally found with bits of the red blood-corpuscles, and pigmented masses derived from them, within their bodies. But the spleen not only destroys blood-corpuscles; it forms new ones, and these are poured out of the pulp into the splenic vein, and are carried off in the general circulation. Most of these new corpuscles appear to be of the white variety, for an abnormally large number of these are by some observers found in the splenic vein, these white corpuscles changing, aided by the spleen itself, into red ones.

There is little doubt that in a general way the spleen is a blood-modifying gland, and in diseases such as splenic leucocythemia it becomes enormously enlarged, and produces large numbers of white corpuscles. In intermittent fever it is also enormously enlarged, forming the ague-cake. It may, however, be excised, even in the case of man, without producing fatal consequences, the lymphatic glands enlarging and the bone marrow undergoing changes, probably to enable them to compensate for the loss of the other organ.

The spleen was long supposed to be the seat of some of the less amiable emotions—envy, malice, &c.

Spleenwort, any fern of the genus Asplenium. See FERNS, Vol. IV. p. 590.

Splenic Fever. See ANTHRAX.

Splicing. See KNOTS.

Splint, or SPLENT, is a bony enlargement on the horse's leg, between the knee and fetlock, usually appearing on the inside of one or both fore-legs, frequently situated between the large and small canon bones, depending upon concussion, and most common in young horses that have been rattled rapidly along hard roads before their bones are consolidated. When of recent and rapid growth, the splint is hot and tender and causes lameness, especially noticeable when the horse is trotted along a hard road. A piece of spongiopiline saturated with cold water should be applied to the splint, kept in position with a light linen bandage, and wetted with cold water or a refrigerant mixture every hour. Perfect rest must be enjoined for ten days or a fortnight. When the limb is cool and free from tenderness, the swelling, which will still remain, may be greatly reduced by some stimulating applications, such as the ointment of the red iodide of mercury, the common fly-blister, or the firing-iron. For the splint-bones, see HORSE, Vol. V. p. 790.

Splints, in Surgery, are certain mechanical contrivances for keeping a fractured limb in its proper position, and for preventing any motion of the ends of the broken bone; they are also employed for securing perfect immobility of the parts to which they are applied in other cases, as in diseased joints, after resection of joints, &c.

Ordinary splints are composed of wood carved to the shape of the limb, and padded; the best pads being made out of old blankets, which should be cut into strips long and wide enough to line the splints, and laid in sufficient number upon one another to give the requisite softness. The splints should be firmly bound to the limb with pieces of bandage, or with straps and buckles; care being taken that they are put on sufficiently tight to keep the parts immovable, and to prevent muscular spasm, but not so tight as to induce discomfort. Gutta-percha, sole-leather, or pasteboard, after having been softened in boiling water, may in some cases advantageously take the place of wooden splints. They must be applied when soft to the part they are intended to support, so as to take a perfect mould, and then be dried, stiffened, and, if necessary, lined. Perforated tin or zinc is sometimes used to form splints. An account of the more complicated kinds of splint required in certain cases, as Macintyre's Splint, Liston's Splint, &c., may be seen in any illustrated catalogue of surgical instruments.

The ordinary splint is now to a great degree superseded by immovable bandages, which consist of the ordinary bandage saturated with a thick mucilage of starch, with glue, or with water-glass (a solution of silicate of soda). As, however, these bandages require some hours to dry and become rigid, means must be used to counteract any displacement of the limb in the interval. On this account many surgeons prefer the plaster of Paris or gypsum bandage, which is applied in the following manner: the limb being protected by a layer of cotton-wool, a bandage composed of coarse and open material, into which as much dry powdered gypsum as possible has been rubbed, must be immersed in water for about a minute, and then rolled around the limb in a spiral manner, just as an ordinary bandage; after every second or third turn of the bandage, the left hand of the surgeon should be plunged into water, and smeared over the part last applied. When the whole has been thus treated, the exterior of the bandage should be smeared over with a paste of gypsum and water until a smooth surface and complete rigidity have been attained—a process not occupying more than ten minutes or a quarter of an hour.

Splügen, an Alpine pass in the Grisons, Switzerland, situated at an altitude of 6946 feet. It connects the valley of the Farther Rhine with that of a tributary of the Adda, and has been used for crossing the Alps since the time of the Romans. The existing road, 24 miles long and 14½ feet wide throughout, was made by the Austrian government in 1812-22. It is protected against avalanches by several galleries and refuges.

Spohr, LUDWIG, composer and violinist, was born at Brunswick on 5th April 1784. His talent for music was shown early, and attracted the notice of the duke, who lent him valuable support in his studies. This patronage he justified by establishing a high reputation as a performer on the violin. In 1805 he was appointed music director at the court of Saxe-Gotha, but gave up that post in 1813 to become music director of the Theater an der Wien at Vienna. There, however, he stayed only two years, and afterwards spent a similar period (1817–19) in a similar position at Frankfort-on-the-Main. In 1820 he appeared in London, where he was received with great applause at the Philharmonic Society's concerts. On the recommendation of Weber, he was in January 1822 appointed Kapellmeister at the court of Hesse-Cassel, which post he continued to hold till 1857. He died on 22d October 1859. The best of his numerous musical compositions are the operas *Faust*, *Jessonda*, and *Zemira und Azor*: the oratorios *Die letzten Dinge*, *Des Heilands letzte Stunden*, and *Der Fall Babylons*; nine grand symphonies, the finest *Die Weihe der Tone*; fifteen very highly esteemed violin concertos; besides sonatas for violin and harp, fantasias, and rondos. *Die letzten Dinge*, or Last Judgment, is a very grand and attractive work; so also is *Der Fall Babylons*, first produced at a Norwich musical festival (1842). As a violinist Spohr deservedly ranks as one of the greatest amongst German masters of the instrument. His *Violinschule*, a manual for advanced violin-players, is almost indispensable for any student who aspires to mastery of technique as a performer.

See his Autobiography (Eng. trans. 1864), and biographies by Malibran (1860) and Schletterer (1881).

Spokane Falls, the third city of Washington, the metropolis of the eastern portion of the state, on the Spokane River and on several railroads, by the Union Pacific 481 miles NE. of Portland, Oregon. It is largely engaged in the lumber trade. A fire in August 1889 destroyed some $6,000,000 worth of property. But the city is chiefly remarkable for its rapid growth. Pop. (1880) 350; (1890) 19,922.

Spoleto (Lat. *Spoletium*), an archiepiscopal city of ancient Umbria in the middle of Italy, is situated on a rocky hill, 75 miles by rail N. by E. of Rome. It is commanded by a citadel, which dates from the days of the Goths, and has a fine cathedral, built in the time of the Lombard dukes, and containing fine frescoes by Lippo Lippi. The churches of St Domenico, St Peter, St Gregory, and St Nicholas present interesting architectural features. Water is brought to the city by a 7th-century aqueduct, 270 feet high and 680 long. The ancient *Spoletium* had its origin in a Roman colony planted here about 240 B.C.; Hannibal (q.v.) was repulsed in an assault he made on the town (217 B.C.) after the battle of Lake Trasimene. Under the Lombards it became the capital of an independent duchy, and its dukes ruled over great part of Central Italy. Having been united to Tuscany, it was bequeathed by the Countess Matilda to the pope (1115). Spoleto has manufactures of woollens and hats. Pop. 7696.

Sponges (*Porifera*), a class of animals whose type of structure is simpler than that of all the other multicellular forms or Metazoa. For the body of a sponge is not differentiated into organs, and tissues are only, as it were, in the making. Almost all are marine, occurring from the shore to the great depths. Except as embryos, they are always fixed to rocks, or in the mud, or upon seaweeds, or on other animals. Their sedentary life, the usual absence of any marked contractility, their frequently herb-like growth, and other characters, led early naturalists to regard sponges as plants; but their animal nature is at once evident when we examine into their internal structure and activities, or when we trace their development. Yet they remained puzzles for centuries. Peyssonnel regarded them as worm-nests, for were not worms found inside of them? Lamarck thought they were colonies of polypes, but the polypes were not to be seen. In popular classification they were ranked with seaweeds. A great step was made when, about 1820-25, Robert Grant observed the water-currents which pass in by minute pores all over the surface and pass out by the larger apertures. Since then our knowledge of sponges has been rapidly progressive.

If we examine a very simple sponge, such as Ascetta, we see a small vase-shaped body, fixed at its base, open at the apex. Examined microscopically this vase shows an internal layer of ciliated cells, a very delicate external skin, and between these a middle stratum in which lie numerous needles of lime, which form the supporting skeleton of the sponge. Through the walls run numerous fine canals, and if we observe a larger sponge living in water with which a little powdered carmine has been mixed we can verify Grant's observation that water passes in by minute pores all over the surface and passes out by the larger apical apertures. On these currents of water, which continually feed and refresh the body, the life of the sponge depends. Every Metazoon organism is 'a city of cells'—a sponge is peculiarly Venice-like. The currents are sustained by the activity of the internal ciliated cells, which by their ceaseless lashing draw the water inwards and drive it also outwards, and at the same time absorb food-particles which drift along in the current.

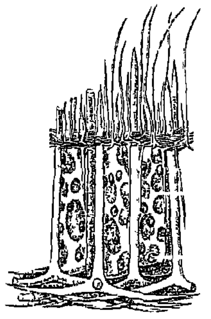

Fig. 1.—Section through wall of *Sycilla chrysalis*, showing various kinds of spicules, and pores in the wall.

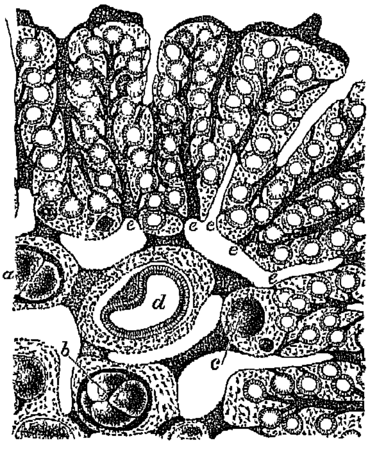

Fig. 2.—Section of part of a Sponge, *Oscarella lobularis* (after Schulze), showing afferent canals, ciliated chambers, efferent canals, internal cavities (*e*, *e*), segmenting ova (*a*, *b*, *c*, *d*).

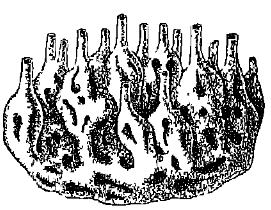

Fig. 3.—Figure of *Leucandra saccharata*, showing mode of growth by budding.

But few sponges are so simple as the vase-like Ascetta; we are familiar, for instance, with the complex 'horny' skeleton of the bath-sponge (Euspongia), or with the beautiful flinty framework of the Venus' Flower-basket (Euplectella); and an examination of the fresh-water sponge (Spongilla) of the lake or canal, or of the Mermaids' Gloves (Chalina) so often cast up half alive on the beach, convinces us that the structure of the soft parts is also relatively complex. Yet with the simple primitive cups, the most complex forms are connected by a gradual series of steps, and simple cups they all are when very young. Let us consider briefly how the complication of structure is brought about.

(1) The vegetative character of sponges is shown by the prolific way in which buds grow out from the parent body. These buds may produce other buds, and the walls of neighbour-buds may fuse; in this way there arise from an original sac like form complex structures puzzling to those who seek logical clearness as to the nature of animal individuality (see fig. 3).

(2) In the simple Ascon type the internal cavity is lined by the characteristic Monad-like, 'collared,' ciliated cells. If this layer grow more rapidly than the outer strata it will naturally become folded into a number of side-aisles, and this is seen in the Sycon type of calcareous sponges, in which the characteristic collared and ciliated cells are restricted to a series of radial chambers around the central cavity. If a similar process of folding occur in the radial chambers the characteristic collared and ciliated cells become restricted to little ciliated ampullæ or chambers, which afferent canals from the surface enter, and from which efferent canals lead to the central cavity and thence outwards. This is the state of affairs in the Leucon type of calcareous sponges, and, with further complications, in the great majority of forms.

(3) Another seat of complication is the middle stratum. This is called the mesoglœa in order to emphasise the fact that in sponges, as also in Cœlenterates, it has not the same definiteness as the middle layer or mesoderm which occurs in the Cœlomata, that is, in all animals higher than Cœlenterata. In the simple sponges the middle stratum is very simple, and always it seems to owe its units to contributions from the inner layer or endoderm. In more complex forms, however, the mesoglœa contains a great variety of cells: some skeleton-making, others contractile, others like simple connective tissue, others full of pigment, others forming reproductive elements, and so on. In sponges the outer layer or ectoderm is always unimportant, though it may line the outer portions of the inhalent canals; the mesoderm forms the skeleton and contains the reproductive elements; the inner layer or endoderm is very important, including, as it does, the collared ciliated cells which cause the water-currents and absorb the food, as well as other flattened and often ciliated cells which line the efferent channels.

Life of Sponges.—Although sponges do not move, there is great motor activity in the ciliated cells of the endoderm. Like many other passive organisms sponges are profoundly influenced by their surroundings, for their shapes vary according to the nature of their anchorage and the currents which play around them. Sensitiveness to stimulus is shown by the closure of the little superficial pores and sometimes even of the larger exhalent aperture or apertures. This closure is due to special contractile-cells in the mesoglœa, and in some cases it seems that these are connected with sensitive and nervous cells on the surface. The food of sponges consists of microscopic organisms and particles of organic debris, which are borne by the water-currents, and caught by the ciliated cells which, like so many Monads, swallow first and digest intracellularly afterwards. From the cells which feed surplus nutritive material oozes to adjacent cells, or is passed to mobile amœboid cells in the mesoglœa. Useless debris is also got rid of by the collared cells. Respiration is of course effected by the currents of water which wash the cells, and some of the bright pigments, such as floridine, characteristic of many sponges, readily absorb oxygen. The green pigment of Spongilla is at least closely analogous to chlorophyll.

Reproduction.—Sponges multiply, like many plants, by overgrowth and budding, but the buds remain continuous with the parent mass, though sometimes it happens that small portions are set adrift from a moribund body. As a sponge is but slightly differentiated, as a fragment is a fair sample of the whole body, we can understand the success with which the sponge-farmers bed out portions of sponge in suitable places, leaving them to grow to a size fit for use. But sexual reproduction also occurs in all sponges. The ova and *spermatozoa are included in the mesoglœa, originating* from apparently similar cells. Both unisexual and bisexual *forms occur, in rare cases within one* species. The ova are fertilised by spermatozoa drawn in by the water currents, and development proceeds through several stages before the embryo leaves the parent (see fig. 2).

The life history of the fresh-water sponge, Spongilla, as told by Marshall, is one of interesting vicissitudes. In autumn the sponge begins to suffer from the cold and the scarcity of food, and dies away. But throughout the moribund parent clumps of cells combine into 'gemmules,' which are furnished with capstan-like spicules, and are able to survive the winter. In April or May they float away from the parental corpse, and form new sponges. Some of these are short-lived males, others are more stable females. The ova produced by the latter, and fertilised by the cells of the former, develop into another generation of sponges, which in turn die away in autumn, and give rise to gemmules. The life-history thus illustrates Alternation of Generations (q.v.).

Development.—The development of sponges varies considerably in the different types, but we may sketch that of a calcareous sponge. The fertilised ovum divides completely, and forms a hollow sphere of in part ciliated cells, which escapes from the parent into the water. In the course of a short free-swimming life the ball of cells becomes invaginated, and forms a two-layered gastrula. This fixes itself, mouth downwards. But pores soon appear through the walls; the internal cells which had meanwhile lost their cilia regain them; an exhalent orifice is formed by rupture at the apex; a middle stratum is derived from the inner layer and begins to form spicules: the young sponge is made.

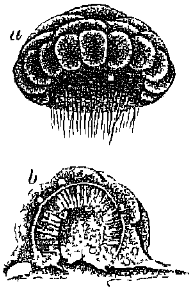

Fig. 4.—Two stages in the development of *Sycandra raphanus* (after Schulze):
a, gastrula, towards end of free-swimming stage; *b*, section of embryo after it has settled down, showing the two germinal layers and the central cavity.

Classification.—One of the oldest and most convenient classifications of sponges is that which distinguishes three main sets according to the nature of the skeleton:

(1) CALCISPONGIÆ: with spicules of carbonate of lime, including Ascon, Sycon, and Leucon types. The purse-like *Sycandra* (or *Grantia*) *compressa* is common on British shores.
(2) SILICISPONGIÆ: with spicules and threads of silica—e.g. the Venus' Flower-basket (Euplectella); the likewise deep-sea Glass-rope Sponge (Hyalonema); Mermaids' Gloves (*Chalina oculata*), with a fibrous as well as a flinty skeleton; the common Crumb-of-bread Sponge (*Halichondria panicea*); Cliona, which bores in oyster shells; *Suberites domuncula*, which grows round a whelk shell inhabited by a hermit-crab; and the fresh-water Spongilla.
(3) CERATOSPONGIÆ: with a framework of spongin or sponge-stuff and no proper spicules—e.g the Bath-sponge (Euspongia), which thrives on some of the Mediterranean coasts.

To these may be added a few, probably degenerate, forms which have no skeleton at all (Myxospongiæ)—e.g. *Oscarella* (or *Halisarca*) *lobularis*.

History.—Sponges, as we should expect, occur in very ancient strata; remains of a flinty form (Protospongia) have been found in Cambrian strata. In succeeding ages they are almost always represented. Remains of calcareous forms are almost confined to one peculiar set of large forms (Pharetrones) in Devonian and several succeeding epochs. Professor Franz Eilhard Schulze—the greatest authority on sponges—divides the sponge branch of the genealogical tree into three: the *calcareous forms to one side, the siliceous* Hexactinellida with triaxial spicules to the other, and *between these the other flinty sponges* whose spicules have four axes (Tetraxonia) or only one (Monaxonia), and the horny sponges without any spicules. It is generally allowed that the sponges are quite distinct from the Cœlenterates, and that they are somewhat degenerate and divergent descendants of the primitive Metazoa.

Relation to other Organisms.—'Sponges are living thickets in which many small animals play hide-and-seek.' Polypes, worms, and some other animals are often found associated with sponges, using them partly for shelter, partly as browsing-grounds. From the appetite of larger animals sponges are doubtless in great part saved by their spicules, and their frequently offensive taste and odour. Some sponges are borers, and others smother forms of life as passive as themselves. Several crabs are masked by growths of sponge, and within several sponges minute Algæ live in constant partnership.

Several species of Euspongia are in use for economic purposes. Two species are brought chiefly from the Levant, and a very inferior one from the West Indies and coast of Florida. The trade in sponge is very considerable; it is carried on chiefly by Greeks, Sicilians, and Tunisians, and by the inhabitants of the Bahama Islands. The number of men employed in the Levantine sponge-fishery is between 4000 and 5000, forming the crews of about 600 boats. These boats find their chief employment on the coasts of Candia, Barbary, and Syria. The sponge is obtained by diving, the diver taking down with him a flat piece of stone of a triangular shape, with a hole drilled through one of its corners; to this a cord from the boat is attached, and the diver makes it serve to guide him to particular spots. When he reaches the growing sponges he tears them off the rocks, and places them under his arms; he then pulls at the rope, which gives the signal to his companions in the boat to haul him up. The value of sponges collected in Greece and Turkey is from £90,000 to £100,000 annually. The diving-bell and diving-dress are sometimes made use of. The Greeks of the Morea, instead of diving, obtain sponges by a pronged instrument; but the sponges thus collected are torn, and sell at a low price. The best sponges are obtained on detached heads of rock in eight or ten fathoms water.

The sponges of the Bahamas and other West Indian islands are of a larger size and coarser quality; the sponge-trade there employs 500 small vessels and 5000 to 6000 people; in 1890 the crop exceeded 900,000 lb., worth £61,400; and about 215,000 lb., worth £17,000, are sent annually to Great Britain. The sponges are torn from the rocks by a fork at the end of a long pole. To get rid of the animal matter they are buried for some days in the sand, and then soaked and washed.

The domestic uses of sponge are familar to every one. It is also of great value to the surgeon, not only for removing blood in operations, but for checking hæmorrhage. Burnt sponge was once a valued remedy for scrofulous diseases and goitre; but iodine and bromine, from which it derives all its value, are now administered in other forms.

See popular account of sponges by Sollas in Cassell's *Natural History;* E. Haeckel, *Die Kalkschwämme* (1872); *Challenger* Reports on Sponges, by Haeckel, Poléjaeff, Schulze, Sollas; Vosmaer, 'Die Poriferen,' in Bronn's *Thierreich;* Von Lendenfeld, 'A Monograph of Australian Sponges,' *Proc. Linn. Soc. N.S. Wales* (vol. ix. 1884).

Spontaneity. See NERVOUS SYSTEM, WILL.

Spontaneous Combustion is a phenomenon that occasionally manifests itself in mineral and organic substances. For some facts connected with the spontaneous ignition of *mineral* substances, see PYROPHORUS. Ordinary charcoal does not undergo combustion in air below a temperature of 1000°, but in some states, especially when impregnated with oil, it is liable spontaneously to acquire a temperature which may lead to unexpected combustion. There have been many instances of the spontaneous ignition of coals containing iron Pyrites (*q.v.*) when moistened with water. The pyrites which most readily give rise to spontaneous combustion are those in which the protosulphide is associated with the bisulphide of iron; and these occur among the Yorkshire coals and in some kinds of South Wales coal. Sulphur has no tendency to spontaneous combustion, but Dr Taylor refers to an instance that came to his own knowledge, in which there was reason to believe that the vapour of bisulphide of carbon in an india-rubber factory was ignited by solar heat traversing glass. Phosphorus, when in a dry state, has a great tendency to ignite spontaneously, and it has been observed to melt and take fire (when touched) in a room in which the temperature was under 70°. The ordinary lucifer-match composition is luminous in the dark in warm summer nights, which shows that oxidation, and therefore a process of heating, is going on. Hence large quantities of these matches kept in contact may produce a heat sufficient for their ignition. 'I have seen them ignite,' says Dr Taylor, 'as a result of exposure to the sun's rays for the purpose of drying.'

In *organic* substances, apart from the accidents that may result from the admixture of strong nitric or sulphuric acid with wool, straw, or certain essential oils, and which, if they occur, are immediate and obvious, there are many cases in which, 'without contact with any energetical chemical compounds, certain substances—such as hay, cotton and woody fibre generally, including tow, flax, hemp, jute, rags, leaves, spent tan, cocoa-nut fibre, straw in manure-heaps, &c.—when stacked in large quantities in a damp state, undergo a process of heating from simple oxidation (eremacausis) or fermentation, and after a time may pass into a state of spontaneous combustion' (Taylor). Cotton, woollen articles, hemp, tow, and flax impregnated with oil, when collected in large quantity, are specially liable to ignite spontaneously; and the accumulation of cotton-waste, used in wiping lamps and the oiled surfaces of machinery, has more than once given rise to accidents, and led to unfounded charges of incendiarism. Dr Taylor relates a case in which a fire took place in a shop 'by reason of a quantity of oil having been spilled on dry sawdust.' According to Chevallier, vegetables boiled in oil furnish a residue which is liable to spontaneous ignition. The great fire at London Bridge in 1861 was referred to the spontaneous combustion of jute in its ordinary state; but Dr Taylor remarks that this is wholly incredible, and from experiments which he made for the defendants in the case of Hepburn *v.* Lordan (1865), and on other grounds, he holds that there is even no evidence of moist jute undergoing spontaneous combustion. Dry wood is supposed by Chevallier and some other chemists to have the property of igniting spontaneously. Deal which has been dried by contact or contiguity with flues or pipes conveying hot water or steam at 212° is supposed to be in a condition for bursting into flame when air gets access to it; and the destruction of the Houses of Parliament, and many other great fires, have been ascribed to this cause; but it appears that some amount of charring is necessary, and that on slight cooling a considerable quantity of oxygen is absorbed from the air, which induces a sufficient rise of temperature to set up spontaneous combustion. In a case recorded in the *Annales d'Hygiène* for 1841, MM. Chevallier, Ollivier, and Devergie drew the conclusion that a barn had caught fire from the spontaneous combustion of damp oats which were stored in it. No such cases are known to have occurred in Great Britain. See also FIRE, p. 634; and GUN-COTTON, p. 468.

Spontaneous combustion of the *human body* is supposed to have occurred in a number of recorded cases, of which one of the earliest was that of Mme. Millet at Rheims in 1725, and one of the most notable that of a man found burning in bed in 1847 (*Gazette Médicale*, 4th September 1847). Some of the alleged cases have been traced to wilful burning after murder; some are plainly incredible; the remainder, with the exception of the 1847 case, which remains unexplained, can all be traced to the destruction of the bodies of intoxicated brandy-drinkers, near an open fire in winter, with no one present and no evidence forthcoming as to the time occupied in the combustion, or as to the circumstances, other than intoxication, preceding the combustion. Liebig discusses the subject in his *Letters on Chemistry*, and concludes that, while a fat dead body charged with alcohol may perhaps burn, a living body, in which the blood is circulating, cannot take fire under any circumstances.

For further details the reader is referred to Graham's 'Report on the Cause of the Fire in the *Amazon*,' in the *Quarterly Journal of the Chemical Society*, vol. v. p. 34; to the article 'Combustion' in Watts's *Dictionary of Chemistry*, vol. i.; and to the elaborate chapter on this subject in Taylor's *Principles and Practice of Medical Jurisprudence.* For spontaneous combustion in the human body, see the article thereon in the Medical Encyclopædias; the preface to Dickens's *Bleak House;* Liebig's *Letters on Chemistry;* Dupuytren's *Leçons Orales;* and Taylor's *Medical Jurisprudence.*

Spontaneous Generation is a term applied to the real or imaginary development of lowly organisms from non-living matter. The facts are that when organic substance is exposed to the air it putrefies, and at the same time living animals—maggots, infusoria, and others, according to the nature and conditions of the substance—appear in it. The question is, whence do the living animals come; from the organic stuff or from germs present in it or in the air? There is a further question—what is the cause of the putrefaction; is it an ordinary process of slow oxidation or is it caused by the living organisms? If the dead organic matter can give rise to life, then we know something of the mode of origin of life upon this planet, for we can make solutions of inorganic salts that will support life, and might therefore also give origin to it; if not, then we are entirely ignorant as to that origin. For many years no one has doubted but that, if one is careful to exclude all germs from the organic stuff, no life can proceed from non-living matter, even if it has once formed part of some living organism and is in the most complex state in which such matter is known to us. The matter is therefore one of historic interest chiefly. As long ago as 1870 Huxley, in his presidential address to the British Association, was able to say that it appeared to him, within certain limitations, that the doctrine of Biogenesis, that life proceeds from life only, was victorious along the whole line. These limitations were, he said, that if he could have been a witness of the early stages of the earth's history, when the physical and chemical conditions were different from those that now hold, he would have expected to see the evolution of living protoplasm from non-living matter. As these limitations are still often thought inconsistent, and as by other people the denial of spontaneous generation seems inconsistent with a belief in evolution, it will be well to quote Herbert Spencer's reply to a critic who urged objections on this ground of inconsistency. In his *Principles of Biology* (vol. i., Appendix, 1868) he says, 'I do not believe in the "spontaneous generation" commonly alleged, and so little have I associated in thought this alleged "spontaneous generation," which I disbelieve, with the generation by evolution, which I do believe, that the repudiation of the one never occurred to me as liable to be mistaken for repudiation of the other. That creatures having *quite specific structures* are evolved in the course of a few hours, without antecedents calculated to determine their specific forms, is to me incredible. Not only the established truths of Biology, but the established truths of science in general, negative the supposition that organisms having structures definite enough to identify them as belonging to known genera and species can be produced in the absence of germs derived from antecedent organisms of the same genera and species. If there can suddenly be imposed upon simple protoplasm the organisation which constitutes it a Paramecium I see no reason why animals of greater complexity, or indeed of any complexity, may not be constituted in the same manner. In brief, I do not accept these alleged facts as exemplifying evolution, because they imply something immensely beyond that which evolution, as I understand it, can achieve. In the second place, my disbelief extends not only to the alleged cases of "spontaneous generation," but to every case akin to them. The very conception of spontaneity is wholly incongruous with the conception of evolution.' On the other hand he says, 'Granting that the formation of organic matter and the evolution of life in its lowest forms *may* go on under existing cosmical conditions, but believing it more likely that the formation of such matter and such forms took place at a time when the heat of the earth's surface was falling through ranges of temperature at which the higher organic compounds are unstable, I conceive that the moulding of such organic matter into the simplest types must have commenced with portions of protoplasm more minute, more indefinite, and more inconstant in their characters than the lowest Rhizopods—less distinguishable from a mere fragment of albumen than even the Protogenes of Professor Haeckel. The evolution of specific shapes must, like all other organic evolution, have resulted from the actions and reactions between such incipient types and the environment, and the continual survival of those which happened to have specialities best fitted to the specialities of their environments. To reach by this process the comparatively well-specialised forms of ordinary infusoria must, I conceive, have taken an enormous period of time.' Again, 'That organic matter was not produced all at once, but was reached through steps, we are well warranted in believing by the experience of chemists. Organic matters are produced in the laboratory by what we may literally call *artificial evolution*. Chemists find themselves unable to form these complex combinations directly from their elements, but they succeed in forming them indirectly by successive modifications of simpler combinations.' We may say then that it is certain that living organisms, large enough to be visible with the help of a microscope and definite enough in form and structure to be classified with other known genera, do not grow at present from non-living matter. But it is not therefore certain that protoplasm of living matter may not be so formed in extremely small quantities, too small to be visible and of simple or no structure, but yet sufficiently complex in composition to serve as food for other and more highly developed animals. Whether this be so or not, Huxley and Spencer and nearly all biologists agree in believing that in past time molecules of simple matter by some series of reactions became aggregated until a matter, sufficiently complex and sufficiently unstable to be called living matter, was formed, whilst there is no evidence that any such generation is taking place at present.

We will now give a summary of the history of this inquiry, based upon Huxley's presidential address of 1870, and to a less extent upon Tyndall's article in the *Nineteenth Century*, January 1878. Expressions and phrases will be freely quoted from these authors.

History.—It must always have been a matter of common experience that many articles of food are apt to become mouldy and to putrefy if kept too long. Associated with mould and with putrefaction are various sorts of low forms of life. The ancient philosophers never doubted that these were generated in the matters in which they made their appearance. Indeed, all men believed this until past the middle of the 17th century. But in 1660 in Italy, in those days the home of learning, Francesco Redi published his *Esperienza intorno alla Generazione degl' Insetti*. He was no theorist, but a careful experimenter. Here, said he, is meat; if I expose it to the air in hot weather, in a few days it putrefies and swarms with maggots; but if I protect similar pieces of meat by covering them with fine gauze, then, though they still putrefy, not a maggot makes its appearance. From this experiment it becomes obvious that the maggots are not generated in the meat, but that the cause of their formation is something that is kept away by fine gauze. This something can be easily shown to be blowflies, for these, attracted by the meat, swarm near it and lay their eggs on the protecting gauze, eggs from which maggots are shortly hatched. Now this is the principle of the whole matter; keep away all living things which might come to the meat and the meat will not create any living things, will not even putrefy if one kills any living animals or germs of animals that may be in the meat. The protecting gauze must be fine enough, that is all. Redi of course was accused of controverting Scripture, because of the story of the bees which were said to be generated in the carcass of the lion. But his doctrine of Biogenesis flourished for a century. Indeed when, through the development of the microscope, the numerous provisions for the production of germs were made known, the hypothesis of Abiogenesis, that life could come from what was not living, appeared absurd. Leeuwenhoek (q.v.), 1632-1723, is remarkable as being the first man to demonstrate existence of unicellular organisms. During the 18th century the microscope was greatly improved. The animalcules (infusoria) which in a few days will swarm in any infusion of organic matter became visible, and Needham, on theoretical grounds, doubted whether Redi's generalisation, 'no life without antecedent life,' held true for these lowly forms of life. He put his doubts to the test. He argued that if the infusorial animalcules came from germs, then the germs must exist either in the substance infused or in the water used to make the infusion or in the air that touches both of them. The life of all germs is destroyed by heat. If, therefore, the infusion be boiled, any germs present will be killed; and then if the infusion be shut off from the air no more germs can get into it. Now, if after this treatment animalcules still appear in the infusion they will have been generated from the infused substance or from the water; but if they do not appear, then Redi's dogma will be true for infusoria. He therefore boiled and corked infusions of various substances, and in every case after a longer or shorter time animalcules appeared and flourished. Needham was associated in much of his work with Buffon. The French naturalist had a theory of life to which Needham's experiments lent support. Life, he thought, was the indestructible property of certain molecules, which he described as 'organic molecules.' All living organisms, he said, are built up of such molecules; death is nothing more than their dissociation. When they are thus set free they take the form of infusorial animalcules. It is necessary to distinguish this theory, which is so ingenious, from the theory of Abiogenesis, the antithesis to that of Biogenesis, which supposes that life may and does arise from non-living matter.

But the theory of Buffon, and especially the experiments of Needham, which lent it support, did not seem satisfactory to Spallanzani. He saw two sources of error—first, the germs present in the infusion might have escaped death through not having been boiled long enough; and secondly, the corks, perhaps, were not perfectly effective, and air containing germs might have got into the flask and infected the infusion. So he too prepared infusions; but he boiled them for three-quarters of an hour, and then fused the necks of the flasks. He found after this treatment that the infusions remained perfectly free from living organisms for as long as he chose to keep them. It might seem that this must be the end of the whole matter; but the event proved otherwise. This time it was the chemists who reopened the discussion. Oxygen was discovered, the theory of respiration was begun, and it was proved that a supply of free oxygen is one of the conditions of life and also of putrefaction. So it was possible that Spallanzani's infusions did not produce life either because the 'organic molecules' were altered in some way by being boiled, or because they were unable, owing to the absence of oxygen, to live. So the experiments had to be repeated in such a manner that the organic matter was not altered, and so that there was sufficient oxygen. Schulze and Schwann in 1836 took up the matter. They carefully boiled their infusions, and then supplied air; but they made it pass through red-hot tubes first, so that any germs present in it would be burned. In these conditions no animalculæ appeared in the infusions; but if they were exposed to air which had not been heated then animalculæ appeared in abundance. Therefore boiling does not injure the vitality of the 'organic molecules,' if there are such, and there is only one possible objection to the conclusions drawn from such experiments, if they be properly conducted, and that is that what the red-hot tubes destroy is not germs, but something else that may be non-living and yet essential to life. Now about this time Cagniard de la Tour discovered that fermentation, like putrefaction, is always accompanied by the presence of minute living creatures. Common yeast, for instance, is a mass of minute plants. When it was suggested that the living creatures not only accompanied but actually caused the processes of fermentation and putrefaction, the chemists, led by Liebig and Berzelius, laughed the idea to scorn. But in 1843 Helmholtz ingeniously separated a putrescent from a putrescible fluid by a membrane, so that the products of putrefaction could mix with the putrescible matter; but that did not in consequence putrefy. Therefore it followed that the cause of putrefaction must be either a colloid—indiffusible stuff—or a solid. In 1854–59 Schroeder and Dusch cleared up this point by experiments which were simply refinements upon the original ones of Redi; instead of using a screen of gauze to keep off blowflies they used a screen of cotton-wool, a screen with meshes so fine that not even the tiny germs can pass through them. They boiled infusions, and while the steam was coming off freely they plugged the neck of the flask with cotton-wool. Now this plug did not keep away oxygen, nor did it in any way heat or alter the air that passed to the fluid, as the red-hot tubes of Schulze and Schwann had done, and yet no animalcules appeared in the boiled infusion screened by cotton-wool. It is therefore proved that the cause of putrefaction and fermentation and the origin of the living forms that accompany these processes must be small particles that exist in the air.

But in 1859 Pouchet published his *Hétérogénie.* He once more raised clouds of doubt. It seemed evident to him that spontaneous generation was one of the means that nature employed for the reproduction of living beings. If, he said, all putrefaction is the result of life present, as germs, in the air, then the air in which we live would have almost the density of iron! About this time Pasteur took the matter up, although advised by his friends, in view of the difficulty of the subject, not to do so; at least, said Dumas, do not spend too much time over it. But in 1862 he published a paper *On the Organised Particles existing in the Atmosphere.* He had collected the floating dust of the air and examined it with a microscope. He saw that much of it actually consisted of organised particles, and on his sowing these in suitable sterilised infusions there grew from them rich crops of animalculæ. He also showed that these germs of life were not universally diffused in the air. He opened his sealed flasks in the pure air of the Mer de Glace. Only one out of twenty such flasks thus opened became filled with life; while eight out of twenty opened in the air of the plains did so, and all of them did so if opened in the air of towns. These researches of Pasteur were necessary before Lister could have brought his system of antiseptic surgery to a successful issue; while he himself, as is well known, has done great work upon the relations of these forms of life to many industries and diseases. The germs of the air were then studied by Cohn, shown by him to be bacteria, and the basis of a sound knowledge of them was laid. In 1869 Tyndall hit upon a very precise method of determining the absence or presence of dust particles in the air, a method much more searching than that furnished by the most powerful microscope. He was experimenting in another direction, and had need of air free from dust. He noticed that such matter (dust) passed easily through liquids. A beam of light shows the presence of dust particles in the air by the reflection that occurs from the surfaces of such. Tyndall showed that whenever dust was present the putrefaction occurred sooner or later, when it was absent it did not. Tyndall's apparatus was a box with glass sides, into the bottom of which the mouths of flasks penetrated, the lower parts being outside the box, so that the contained infusions could be boiled. A beam of sunlight was allowed to pass through the box; it showed the presence of dust in the air in a way with which every one is familiar. The inside of the box was then coated with glycerine, and the whole was kept as still as possible. After some time the dust particles sank to the floor of the box, and stuck to the glycerine, and a beam of sunlight passing through was quite invisible, there not being anything to reflect it. The infusions were then boiled for a long time, and then allowed to cool, after which they might be kept for months without putrefying or showing any signs of the presence of life. Here all the conditions of the infusions were natural, save that there was no dust in the air above them. In the dust of the air therefore are solid germs of life. The opponents of the doctrine of Biogenesis had long made objection to it, saying that 'if true then the air must be thick with germs; now this is absurd, therefore the doctrine is untrue.' An argument this that shows that a *reductio ad absurdum* is not always a proof.

The researches of Tyndall called forth the first utterances on the subject of Bastian, the latest, let us hope the last, obscurantist. Two years later, 1872, Bastian published his work, in two volumes, upon *The Beginnings of Life*. In the preface he states that the question of spontaneous generation turns wholly upon the probability of the *de novo* origin of bacteria, and further that evidence of the most convincing character shows that bacteria are killed by a temperature of 140° F., yet similar organisms will constantly appear in closed flasks containing organic fluids that have been exposed for some time to a temperature of 212° F. It is surprising that any man could at that late day have been found to urge such stale arguments after the repeated demonstration of the two sources of error in such experiments—(1) that fresh bacteria might get in after the original set were killed; (2) that though adult bacteria are killed by a temperature of 140° F., their germs are not always killed by a much higher temperature. Bastian's work has been quietly forgotten, and since then the progress of discovery as to the nature and mode of origin of bacteria and all other forms of life has progressed steadily.

See BACTERIA, BATHYBIUS, LIFE, PROTOPLASM, PUTREFACTION; and Haeckel's *Natural History of Creation*.

Spontini, GASPARO LUIGI PACIFICO, Italian musical composer, was born at Majolati in the March of Ancona on 14th November 1774, and received his musical education at Naples. In 1803 he proceeded to Paris; but it was not until he produced (1804) the one-act opera of *Milton* that he attracted any notice. Encouraged by this, he composed the grand opera *La Vestale*; this on its production in December 1807 was greeted with enthusiastic acclaim, and was adjudged the prize of 10,000 francs instituted by Napoleon. An equally warm reception was accorded to *Ferdinand Cortez* in 1809. In the following year Spontini was appointed director of Italian opera at the Odéon. A third grand opera, *Olympia*, produced in 1819, did not prove so successful. In 1820 Frederick-William III. summoned Spontini to Berlin. There he remained more than twenty years, though during the greater part of the time it was only court influence that supported him against the enmity of the Berlin public and of the Prussian press. Spontini was jealous of Weber, and was by nature quarrelsome and vain; but as a musician he entertained the loftiest aims, possessed true artistic taste, was grandiose in his conceptions, and breathed the spirit of genuine melody into his compositions. In Berlin he wrote three other grand operas—*Nourmahal* (1822), *Alcidor* (1825), and *Agnes von Hohenstaufen* (1829), his greatest work. Spontini was dismissed by Frederick-William IV. in 1842, and he gradually withdrew into private life. He died at Majolati, his birthplace, on 14th January 1851. See monograph by Robert (Berlin, 1883); and Spitta in *Deutsche Rundschau* (March 1891).

Spontoon. See PIKE.

Spoonbill, a family of birds, Plataleidæ, allied to the Ibididæ, and more distantly to the storks, and distinguished by the remarkable form of the bill, which is long, flat, broad throughout its whole length, and much dilated in a spoon-like form at the tip. The species are not numerous, but are widely distributed; the birds are, however, becoming scarce owing to the drainage of their native haunts. The only European species is the White Spoonbill (*P. leucorodia*), at one time a resident in Britain, but now only a visitor. This bird was known as the Shovelard or Shovelar, while the bird now known as the Shoveler was then called the Spoonbill or Spoonbilled Duck. In northern Europe it is uncommon; it breeds in Holland, in the south of Spain, and the Black Sea district. Eastward in summer it ranges to India, Ceylon, and northern China; it is resident in North Africa. In South Africa it is represented by another species, *P. tenuirostris* or *cristata*. It is gregarious, but its nesting habits vary in different countries; in Holland the nests are made of reeds, and placed on the mud among rushes; in Slavonia on the submerged branches of willows; and in India on trees. It is about 32 inches long. Its colour is white, slightly tinged with pink; the bill and legs are black. A curious convolution of the windpipe, in the form of a figure 8, is found on dissection in the adult spoonbill, but does not exist in the young. The flesh of the spoonbill is said to be tender and of good flavour. The spoonbill is easily tamed, is quiet and inoffensive, and feeds readily on any offal. The Roseate Spoonbill (*P. ajaja*) is an American species, and the only one; very abundant within the tropics, and found in the most southern parts of the United States. It is nearly equal in size to the White Spoonbill, which it resembles in its habits. It is a beautiful bird, with plumage of a fine rose-colour, of which the tint is deepest on the wings; the tail-coverts are crimson. Two species (*P. regia* or *melanorhynchus* and *P. flavipes*) are found in Australia.

Spoonbill (*Platalea leucorodia*).

Sporades. See ARCHIPELAGO.

Sporadic (Gr., 'scattered') is a term applied to any disease that is commonly epidemic or contagious, when it attacks only a few persons in a district and does not spread in its ordinary manner. The conditions which determine the occurrence of epidemic or contagious diseases in a sporadic form are unknown. Amongst the diseases which occur in this form may be especially mentioned cholera, dysentery, measles, scarlatina, and smallpox.

Spore. Plants reproduce themselves in two different ways, 'vegetatively' or 'truly.' The vegetative mode of reproduction is merely a continuous growth of parts already formed. It is quite common in nature. Sometimes entire buds separate from the parent plant and produce independent plants. This happens, for example, with some of the buds in the axils of the leaves of *Lilium bulbiferum.* Sometimes entire pieces of a creeping stem separate from the main stem and begin an independent life. This happens in the case of the strawberry plant. Artificially also a vegetative mode of reproduction is easily brought about. Every one knows how gardeners propagate many species of plants by means of cuttings. As a rule the more lowly the plant the more easy is it to make a successful cutting, and the smaller may the cutting be. Thus, a single leaf or even a small part of leaf of a moss plant will often, if cut off and placed in a suitable soil, grow into a complete moss plant. In the true mode of reproduction the growth is not continuous. Certain cells of a plant are set apart for this function. These cells are called *spores.* In plants higher than the Thallophytes such cells do not grow directly into a plant like that from which they have come, but they give rise to a plant which in its turn, when it reaches maturity, produces cells of two sorts, male and female, which unite with one another, and then from the new cell of dual origin there grows a plant like that from which the spore originally came. Thus, on the under surface of the fronds of ferns there may often be seen many small spore-cases. The spores fall to the ground, and produce a little green plant called the prothallium of the fern. The prothallium produces the sex-elements. These unite, and from their union grows a new 'fern.' This indirect mode of reproduction is spoken of as the Alternation of Generations (q.v.).

In the Thallophytes (Algæ, Fungi, &c.) the cells which function as spores receive a variety of names, such as teleutospores, æcidospores, sporidia, stylospores, tetraspores, zoospores (which are motile), conidia, &c. These names are meant to emphasise some point in their mode of origin and development. In the Bryophytes (liverworts and mosses) and in the Pteridophytes (ferns, horsetails, &c.) they are always called simply spores. But some of the Pteridophytes (Vascular Cryptogams), for instance Salvinia (q.v.), produce two kinds of spores, male and female, and hence they are called *heterosporous* ferns, horsetails, or lycopods as the case may be. In the Spermophytes also (Seed-plants or Phanerogams) the spores are of two kinds. The pollen grains (see FLOWER) represent the male spores, microspores; and the female spores are contained within the Ovule (q.v.).

The sexual generation, the prothallium, which is formed from the spore, loses its character as an independent plant as we ascend the scale of plants from the Vascular Cryptogams to the Phanerogams. In homosporous ferns it lives for a long time; in the heterosporous ferns they, the male and female prothallia, never become entirely separate from the spores, although they burst through the spore-cases; in the Coniferæ they remain entirely within the spore-case. In the Phanerogams they are still further reduced; the Ovule (q.v.) is the macrosporangium. Details as to the structure, mode of formation, and germination will be found in the articles that treat of the various groups of plants—Algæ, Ferns, Fungi, Mosses, &c.

Sporozoa. See GREGARINIDA.

Sporran. See HIGHLANDS, Vol. V. p. 711.

Sports, BOOK OF, the name popularly given to a Declaration issued by James I. of England in 1618, to signify his pleasure that on Sundays, after divine service, 'no lawful recreation should be barred to his good people, which should not tend to the breach of the laws of his kingdom and the canons of his church.' The sports specified were dancing, archery, leaping, vaulting, May-games, Whitsun-ales, morris-dances, and the setting up of May-poles. The occasion of this proclamation was the conduct of some Puritan authorities in Lancashire, who, by illegally suppressing instead of regulating the customary recreations of the common people, had excited much discontent, and increased the influence of the Roman Catholics by giving a repulsive aspect to the Reformed religion. Although the Declaration was ordered to be read in the parish churches of the diocese of Chester, this order was not enforced, and the king's design was allowed to drop. Among the excepted unlawful sports were bear-baiting, bull-baiting, bowling, and interludes. Nonconformists and others not attending divine service at church were prohibited from joining in the sports, nor was any one allowed to go out of his own parish for that purpose, or to carry offensive weapons. By republishing this Declaration in 1633, and enforcing with great severity the reading of it by the clergy in their churches, Charles I. and Laud excited among the Puritans a degree of indignation which contributed not a little to the downfall of the monarchy and the church. In 1644 the Long Parliament ordered all copies of it to be called in and publicly burned. See L. A. Govett, *The King's Book of Sports* (1890).

Spottiswoode, JOHN, Archbishop of St Andrews, son of John Spottiswoode, Superintendent of Lothian, was born in 1565. He was educated at the university of Glasgow, and at eighteen succeeded his father as parson of Calder. In 1601 he attended the Duke of Lennox as chaplain on his embassy to France, and in 1603 King James to London. Soon after he succeeded James Beaton as Archbishop of Glasgow, but was only consecrated in London in 1610. As Moderator of the General Assembly at Glasgow in 1610 he laboured to confirm episcopal government, and he forced the Perth Assembly (1618) to sanction the five points of discipline known as the Perth (q.v.) Articles. He was translated to the see of St Andrews in 1615. He officiated at the coronation of Charles I. at Holyrood in 1633, and in 1635 became Chancellor of Scotland. He reluctantly entered into the king's unwise measures for the introduction of a liturgy into Scotland, and naturally became hateful to the Covenanters. The king compelled him to resign the chancellorship in 1638, and that same year the Glasgow General Assembly deposed and excommunicated him. Spottiswoode died at London, 26th November 1639, and was buried in Westminster. His chief work is the well-known *History of the Church of Scotland* (1655; 3 vols., ed., with a Life, by Bishop Russell for the Spottiswoode Society, 1847–51).

Spottiswoode, WILLIAM, mathematician, was born in London, January 11, 1825, and was educated at Harrow and Balliol College, Oxford. He took a first-class in mathematics in 1845, and later both the junior and senior university mathematical scholarships. For some time he lectured at Balliol, and in 1846 he succeeded his father as the head of the great printing-house of Eyre & Spottiswoode. Although throughout life an energetic man of business, he found time for much original work in abstract mathematics and experimental physics; as well as for travels in Eastern Russia (1856), Croatia and Hungary (1860), and for a large hospitality at his houses both in London and at Sevenoaks. His contributions to the *Proceedings* of the Royal Society, the *Philosophical Magazine,* the London Mathematical Society *Proceedings*, and his admirable lectures on the *Polarisation of Light*, reprinted in the 'Nature' series (1874), are known to all students. Spottiswoode was treasurer of the British Association (1861-74), of the Royal Institution (1865-73), and of the Royal Society (1871-78); president of Section A (1865), and of the British Association itself (1878), of the London Mathematical Society (1870-72), and of the Royal Society from 1879 till his death, which took place at London, June 27, 1883. Further honours were the degrees of LL.D. from Cambridge, Dublin, and Edinburgh, and D.C.L. from Oxford. For a brief memoir and a list of his writings, see *Nature* for April 26, 1883.

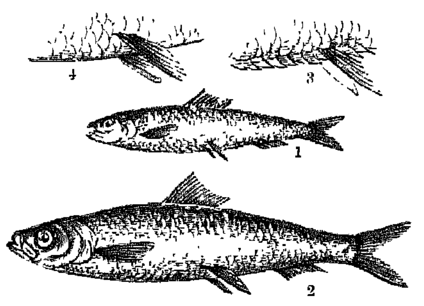
Spottsylvania Courthouse, a small village of Virginia, 55 miles N. by W. of Richmond, the scene of one of the most desperate and sanguinary battles of the civil war. On 10th May 1864, during the Wilderness campaign, Grant attacked Lee in his earthworks, and was repulsed with dreadful slaughter; yet on the next day he wrote to the secretary of war, 'I propose to fight it out on this line, if it takes all summer,' and on the 12th repeated the assault, when Hancock's corps carried and held the 'bloody angle' (see HANCOCK). The next morning Lee, unable to bear his share of the heavy losses, withdrew within an inner line of entrenchments, and on the 20th Grant, having failed to dislodge him, moved round his flank towards Richmond.

Sprain, or STRAIN, is a term employed in Surgery to designate a violent stretching of tendinous or ligamentous parts with or without rupture of some of their fibres. Sprains are very frequent in all the joints of the upper limbs, especially in the wrist and the articulations of the thumb. In the lower extremity the ankle is the joint by far the most frequently affected; and this is accounted for anatomically by the small size of the articular surfaces, the great weight the astragalus (the bone presenting the lower articular surface) has to support, and the unyielding nature of the lateral ligaments. In slight sprains of this joint the ligaments are only stretched or slightly lacerated, but in more severe cases they may be completely torn through. Sprains of the ankle are sometimes mistaken for fractures, and *vice versâ;* and the two injuries may co-exist. The pain and swelling sometimes make an accurate diagnosis difficult, especially if the patient is not seen for some time after the accident; and if any doubt exists the case should be treated as for the more severe injury, since it is better that the treatment should be prolonged than that the patient should be maimed; and fortunately that which is the proper treatment of a fracture will also suit a sprain well, at least till the swelling subsides, and the doubt can be resolved. Sprains of the knee are not uncommon, and are characterised by great swelling from effusion of fluid within the joint. Sprains of the back are not unfrequent accidents, and are the most serious of any, but in most cases it may be anticipated that after confinement in bed or on a sofa for two or three weeks, and with proper treatment, the patient will be able to walk, although he may feel stiffness and pain for several weeks longer.

The best treatment of a sprain depends chiefly upon the time that has elapsed since the injury. If the patient is seen before swelling has occurred the application of cold by means of ice-bags or running water, especially if a thin india-rubber bandage is previously applied, does much to control the swelling and the pain. At a later stage, if the pain be severe, warm applications (hot water, hot fomentations, or poultices) are generally very soothing; or lead and opium lotion may be employed. Where the swelling is very great leeches are sometimes most useful. When the pain is not very intense the joint may be enveloped in a large quantity of cotton-wool, and gently but very firmly bandaged. It is important not to keep the injured joint too long at rest. As soon as the pain has subsided massage and gentle movements should be commenced; the patient should not be allowed to use the limb himself till these can be quite freely borne. In sprains of the back rest is the main requisite; but sometimes active antiphlogistic treatment is required; and a supporting jacket of gutta-percha or plaster of Paris may have to be worn for some time.

Amongst *horses* sprains or strains are very common, owing to the severe exertions required of them, often whilst they are young, and unprepared for such work. Various muscles, ligaments, and tendons are liable to strain, but none more frequently than the large tendons passing down the back of the legs. In slight cases cold water continuously applied for several hours gives relief; but in all serious cases diligent fomentation with water about the temperature of 100° is preferable; or the injured part may be swathed in a thick woollen rug, kept constantly moist and warm by frequent wetting with the hot water. Perfect rest is essential, and in order to ensure the relaxation of the large tendons of the horse's limbs he may in bad cases be kept slung for several days. Blisters, hot oils, firing, and all such irritants are on no account to be used until the inflammation abates and the part becomes cool and free from tenderness. Such remedies are then useful for causing the reabsorption of swelling, and perhaps also for invigorating the weakened part.

Sprat (*Clupea sprattus*), a fish of the family Clupeidæ, very abundant on many parts of the British coast, and elsewhere in the northern parts of the Atlantic. It is smaller than the herring, being only about five inches in length when full grown, but much resembles it. It is, however, easily distinguished by the serrated belly, and by the position of the fins, the ventral fins beginning immediately beneath the first ray of the dorsal fin, and not beneath the middle of it, as in the herring and pilchard. Another easily observed distinction is the want of axillary scales to the ventral fins, which both the herring and pilchard have. The dentition is also different, and on this account Valenciennes constituted for the sprat and a number of other species the new genus Harengula, characterised by having teeth on the jaws, tongue, palatines, and pterygoids, but no teeth on the vomer. The herring has teeth on the vomer. The sprat has only forty-seven to forty-nine vertebræ, whilst the herring has fifty-six to fifty-eight. The mode of reproduction of the sprat has only recently



Sprat and Herring:
1, sprat; 2, herring; 3, belly of sprat; 4, belly of herring.

been discovered. It was for a long time unknown, because the adult sprats taken in estuaries are scarcely ever in breeding condition. But it has now been proved by Victor Hensen of the German Fishery Commission, and by J. T. Cunningham of the Marine Biological Association, that the eggs of the sprat are pelagic, like those of the pilchard—i.e. that they float in the sea and are hatched in that condition. The eggs have been taken both in Germany and at Plymouth in England from the ripe female sprat, and proved to be identical in all respects with floating eggs previously obtained from the surface-waters of the sea. Perfectly ripe sprats are only found in the sea, to which they repair for the purpose of spawning, not, however, wandering very far from land. On the south coast of England at Plymouth the sprat spawns from December to May, but in the Firth of Forth and east coast of Scotland in May or June. The young sprats are found, together with young herrings, in estuaries, such as the Thames, Forth, Exe, Tamar, &c., and are taken in large numbers to be consumed as whitebait. Sprats abound especially on the coasts of Norfolk, Suffolk, Essex, and Kent in November and several following months. Drift-nets are used for the capture of sprats off the coast of Kent, but the usual instrument for the purpose is the stow-net worked from a moored boat in estuaries and tide-ways. The stow-net is a large bag-net suspended between two horizontal beams beneath the boat, and about a fathom from the bottom of the water; ropes from the ends of the upper beam enabling the fisherman in the boat to keep the mouth of the bag always open and against the tide. Vast quantities of sprats are taken in this way, so that they are used as manure by farmers, although London is also very largely supplied with them, and being sold at a very cheap rate they are a favourite article of food of the poorer classes. The Firth of Forth also produces sprats—in Scotland called *garvies*—so abundantly that they are sold both in Edinburgh and Glasgow by measure, and cheaper than any other kind of fish. But there are many parts of the British coast where the sprat is rare, some of these being parts where the herring is plentiful. Notwithstanding its cheapness the sprat is a very fine fish, of flavour quite equal to the herring, although decidedly different. Dried sprats are a very common article of provision, and sprats are also sometimes salted. The *kilkies* brought from Riga and other ports on the Baltic are sprats cured with spices, as also are the 'Norwegian Anchovies' sent in small wooden barrels from Norway to England. The value of the sprat does not seem to be as yet fully appreciated in Britain. Very closely allied to the sprat is another fish (*Clupea latula*), the *Blanquette* of the French, which is caught in great abundance on some parts of the west coast of France. Other allied species are found in other seas. One of them (*C. humeralis*), which abounds in the West Indies, and southwards as far as Rio Janeiro, is much esteemed, but becomes poisonous at certain seasons, from some unknown cause. The prepared Sardine (q.v.) is frequently a sprat.

Spree, a river of Prussia, rises in the east of Saxony, on the borders of Bohemia, and after a winding course of 227 miles, but bearing generally north and north-west, falls into the Havel (q.v.) at Spandau. Area of drainage basin, 3655 sq. m. The principal towns on its banks are Bautzen, Kottbus, and Berlin. By the Frederick-William or Müllrose Canal it is connected with the Oder. A couple of short canals assist navigation near Berlin, and in 1890 it was proposed to spend close upon £1,000,000 in deepening the river and its
hat city so as to afford easy com-
the Oder to the Elbe. In the Spreewald, a district near Kottbus much cut up by the interlacing arms of the river, there still exists a colony of Wends.

Sprengel, KURT, physician and botanist, was born at Boldekow in Pomerania on 3d August 1766, and died at Halle on 15th March 1833. All his life was spent in quiet labour at Halle, from 1789 as professor of Medicine and from 1797 as professor of Botany. He won a reputation as a writer on the history of medicine and as a student of the anatomical structure and functions of plants. His principal books are *Pragmatische Geschichte der Arzneikunde* (5 vols. 1792–1803), *Geschichte der Botanik* (2 vols. 1817–18), and *Neue Entdeckungen im ganzen Umfang der Pflanzenkunde* (3 vols. 1819–22). Rosenbaum edited in 1844 Sprengel's *Opuscula Academica*, with a biography.

Sprenger, ALOYS, orientalist, was born 3d September 1813 at Nassereit in the Tyrol, studied medicine, the natural sciences, and the oriental languages at Vienna, next at London assisted Count Munster, and in 1843 sailed to Calcutta. For many years he was incessantly active as teacher, interpreter, librarian, and translator, until in 1857 he was called to be professor of Oriental Languages at Bern. In 1881 he settled at Heidelberg. His rich collection of Arabic, Persian, Hindustani, and other MSS. and books are now in the Royal Library at Berlin. The most important of Sprenger's numerous works are *Leben und Lehre des Mohammed* (3 vols. 1861–65), *Die Alte Geographie Arabiens* (1875), and *Babylonien* (1886); besides editions of Arabic and Persian works, as Sadi's *Gulistan*, &c.

Sprenger, JACOB, of the Order of Preachers, and professor of Theology in Cologne, and HENRICUS INSTITOR (Latinised form of Kramer), two names of enduring infamy as the authors of the famous *Malleus Maleficarum* or *Hexenhammer* (1489), which first formulated in detail the doctrine of witchcraft, and formed a text-book of procedure for witch-trials. They were appointed inquisitors under the bull 'Summis desiderantes affectibus' of Innocent VIII. in 1484, and their work is arranged in three parts—Things that pertain to Witchcraft; The Effects of Witchcraft; and The Remedies for Witchcraft. It discusses the question of the nature of demons; the causes why they seduce men, and particularly women; transformations into beasts, as wolves and cats; and the various charms and exorcisms to be employed against witches. The writers detail the extraordinary dangers to which they were exposed in their task, and how all the artillery of hell had been employed against themselves in vain, and they tell with complete composure of mind how in one place forty, in another fifty, persons were burned by their means. They admit bodily transmission of sorcerers through the air, and relate numerous cases of the devilish malice of witches upon horses and cattle as well as mankind; and in the latter part, consisting of thirty-five questions, give minute directions for the manner in which prisoners are to be treated, the means to be used to force them to a confession, and the degree of evidence required for a conviction of those who would not confess. The book contains no distinct allusion to the proceedings at the Witches' Sabbath any more than did the *Formicarium* (c. 1440) of John Nider, whose fifth book is devoted to the subject of sorcery.

Spring. See SEASONS.

Spring, a stream of water issuing from the earth. The source of springs is the rain and snow that falls from the clouds. Very little of the water precipitated in any district finds its way immediately by rivers to the sea; the great proportion either sinks into the earth or is evaporated from the surface of the earth, and, reabsorbed by the atmosphere, is employed by plants and animals. All loose soils and gravels greedily absorb water, which descends until it meets with a stratum through which it cannot penetrate. A pit dug into the water-charged soil would speedily fill itself by draining the water from the soil. All rocks contain water; some retain it by capillary attraction, like a sponge, others hold it merely mechanically, and easily part with it. Chalk will absorb and retain one-third of its bulk of water; and sand, on the other hand, while it will absorb as much, will part with nearly the whole amount to a well dug in it. Argillaceous deposits and compact rocks are barriers to the passage of water, and cause the superincumbent pervious strata to become water-logged when there is no outlet. Sometimes the edges of the strata are exposed on the sides of a valley, and permit the free escape of the contained water, which pours from them over the neighbouring land. But rents and fissures, as well as inequalities on the surface of the impervious beds, give the water a circumscribed course, and cause it to issue in springs.

The water, as it percolates through the earth, always becomes more or less charged with foreign matter, owing to its solvent property. Carbonate, sulphate, and muriate of lime, muriate of soda, and iron are the most common impurities in spring-waters; magnesia and silica also frequently occur. These substances, from the evaporation of part of the water, or the escape of the carbonic acid gas, by which so large a quantity is often held in solution, are frequently deposited on the margins of the springs, or in the courses of the streams flowing from them. Such deposits are found in all so-called petrifying springs; and the hot wells of Iceland, the Yellowstone Park, and the Azores are surrounded with basins formed of siliceous sinter which has been derived from the water. When the foreign ingredients have medicinal qualities the springs are known as Mineral Waters (q.v.).

Springs are either associated with the superficial strata or rise from a considerable depth. Surface-springs occur where the absorbent surface-deposits rest on an impervious bed, which prevents the further downward progress of the water, or where the beds through which the water flows are near the surface, as shown in fig. 1, where C and E are impervious clay-beds, and D is a bed of sand or gravel, which in the upper portion is exposed on the surface, or is only overlaid by loose soil, and after being covered for some distance by the clay-bed, C, makes its appearance again at B, where the valley cuts it through: here the water collected over the area, A, is discharged. Surface-springs, depending as they do so directly on the rain for supplies, are very variable in the amount of water they deliver. They frequently fail entirely in the summer, and always after great droughts. Their temperature varies with that of the district where they exist, being warm in summer and cold in winter, as they do not penetrate below that plane in the earth's crust which is affected by the seasonal changes in temperature.

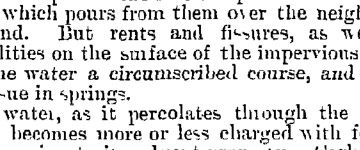


Fig. 1.

When the bed which forms the reservoir for the spring is at such a distance from the surface as to be beyond the zone of season changes, and yet within that which is influenced by the climate, the water has a temperature equal to the mean temperature of the locality where it springs. Such springs have generally a large area for the collection of the superficial water, and are consequently regular in the quantity of water they give out. They are brought to the surface by means of master-joints and dislocations. The celebrated Well of St Winifred at Holywell, in Flintshire, rises through a fault in the coal-measures. It formerly discharged about 4400 gallons per minute, and the water, in its short course of little more than a mile to the sea, was used to propel eleven mills; but the discharge has been much diminished by drainage works.

Most deep wells have a lower origin than the zone of climate temperature, which in Britain is between 200 and 300 feet. It is well known that a regular increase in the temperature is observed after this zone is passed, equal to 1° of F. for every 54 feet. As wells have a temperature corresponding to that of the strata from which they spring, it follows that the deeper the spring the higher will be its temperature. Local conditions may affect the thermal state of springs, as in the case of the geysers in the active volcanic district in Iceland, and the warm springs near Naples; but where no such local influences exist the depth of the bed from which the water comes may be to some extent estimated by its temperature. Thermal springs occur in Britain at Matlock (66° F.) and Buxton (82°) in Derbyshire, at Bath (117°) in Somerset, and at Clifton (76°) in Gloucestershire. Artificial communications have been opened with deep-lying strata, by which the water they contain has been brought to the surface, and in these the temperature is found to increase in proportion to the depth of the bore (see ARTESIAN WELLS). The most remarkable thermal springs are the geysers of Iceland and the Yellowstone Park (see GEYSER, YELLOWSTONE PARK).

Intermittent springs are sometimes produced by the ebb and flow of the tide, as at Richmond, where the rise at high-water is seen in the wells which flow from the arenaceous strata on the banks of the Thames; and sometimes they depend on the supply of rain-water. But there is a kind of spring the intermittences of which are believed to be owing to the structure of the internal cavities from which the supply is obtained. This will be more easily understood by a reference to the accompanying diagram (fig. 2). The large reservoir, A, is fed by the rain percolating through the rock. It communicates with the surface by a siphon-shaped tube, BCD. As long as the water in the reservoir is at a lower level than the arch of the siphon at C no water can escape; but as soon as it reaches its level the whole of the water in the cavity will be drawn off, the spring will then cease, and will only make its appearance when sufficient water has accumulated to permit the siphon again to act.

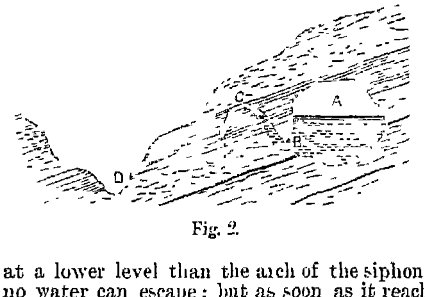

Fig. 2.

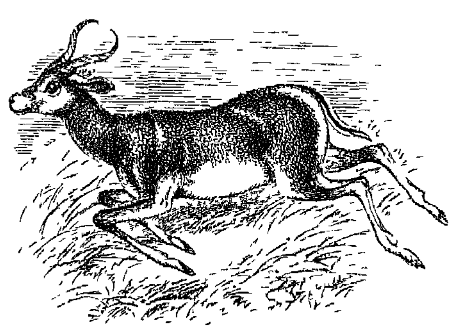
Spring-balance. See BALANCE.

Springbok (*Gazella euchore*), an antelope, which like many others is getting scarcer; it is still, however, abundant a little south of the Zambesi. It is an extremely beautiful creature, of graceful form, and fine colours. It is larger than the roe-buck, and its neck and limbs much longer and more delicate. The general colour is fulvous brown on the upper parts, pure white beneath, the colours separated on the flanks by a broad band of deep vinous red. The whole head is white, except a broad brown band on each side from the eye to the mouth, and a brown spot in the centre of the face. Two curious folds of skin ascend from the root of the tail, and terminate near the middle of the back; they are usually closed, but open out when the animal is bounding, and disclose a large triangular white space which is otherwise concealed. The springbok derives its name from the prodigious leaps which it takes either when alarmed or in play, often to the height of 7 feet, and sometimes of 12 or 13 feet. Its ordinary residence is in the *Karroos* or arid sandy plains; but when all pasture there is burned up immense herds congregate together, and migrate to more fertile regions, often devastating the fields of the colonist. Pringle speaks (1834) of seeing the country near the Little Fish River specked with them as far as the eye could reach, and estimates the number in sight at once as not less than 25,000 or 30,000. Cumming describes (1850) a still more extraordinary scene, a vast herd pouring through an opening among hills, in one living mass, half a mile in breadth, and so continuing for hours together. The strongest animals are generally foremost, but when satiated with food they fall behind, and others, hungry and active, take their place. When taken young the springbok is easily tamed, and becomes very familiar, troublesome, and tricky.



Springbok (*Gazella euchore*).

Springer. See SPANIEL.

Springfield, (1) the capital of Illinois, stands in a fertile prairie country rich in bituminous coal, 185 miles by rail SW. of Chicago, at the meeting-point of seven railway lines. It is regularly laid out with broad streets and gardens, possesses a handsome federal building, a state arsenal, two colleges, and one of the largest state capitols in the Union (of marble, 385 feet long by 296 wide; cost $5,000,000). Its coal-mines have made it an active industrial centre: here are large iron-rolling mills and foundries, a watch-factory, and flour, woollen, paper, and planing mills. Springfield, which became the capital in 1837, was the home of Abraham Lincoln, who is buried in the beautiful Oak Ridge cemetery, in the crypt of the great national monument—a granite obelisk (1874), which cost $264,000. Pop. (1880) 19,746; (1890) 24,963.—(2) A thriving city of Massachusetts, capital of Hampden county, on the left bank of the Connecticut River, by rail 99 miles W. by S. of Boston and 25 N. of Hartford. The river is crossed by five bridges to West Springfield (pop. 5075), and four railways meet here. The city is stretching out over an elevated plain to the east; the older streets are broad, shaded avenues, and there is a large and beautiful park. The public buildings include a cathedral and numerous other churches, a brown-stone post-office, city hall, granite court-house, and a railway station which cost $700,000. Springfield is noted for the great variety of its manufactures. Among its larger factories is the United States Armoury (since 1794), employing about 400 men, chiefly in the manufacture of rifles and carbines; the others embrace foundries, car-works, and manufactories of cottons and woollens, paper, machinery, furniture, trunks, buttons, needles, spectacles, locks, pistols, skates, picture-frames, organs, and jewellery. The town was settled in 1635. Pop. (1880) 33,340; (1890) 44,179.—(3) Capital of Greene county, Missouri, 232 miles by rail WSW. of St Louis, with machine-shops, car-works, and large cotton and woollen factories. Here is Drury College (Congregational; 1873). Near Springfield was fought the battle of Wilson's Creek, 10th August 1861. Pop. (1880) 6522; (1890) 21,850.—(4) Capital of Clark county, Ohio, on Lagonda Creek and Mad River, 80 miles by rail NE. of Cincinnati. Six railways meet here. The city contains the Wittenberg College (Lutheran; 1845), and handsome county and municipal buildings. It has over sixty manufactories, the principal products being farm machinery, bicycles, sewing-machines, iron fences, paper, &c. Pop. (1880) 20,730; (1890) 31,895.

Spring-gun, a gun having wires connected with its trigger, and so fixed and planted that when wild animals, trespassers, &c. stumble against the wire the gun shall be discharged at them so as to wound them. Since 1827 it is illegal in Britain to set Man-traps (q.v.) or spring-guns save indoors as a defence against burglars.

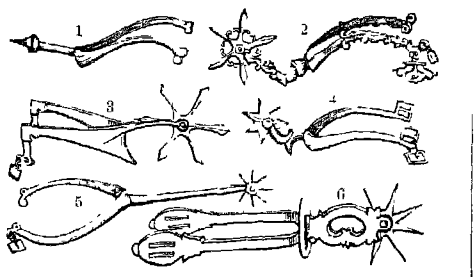
Spring-tails (*Collembola*), an order of primitive wingless insects which, along with the somewhat similar Thysanura, are included in the small group Apterygota. The popular name refers to a peculiar springing fork which is usually present on the abdomen. It seems to result from a pair of abdominal appendages which are united at the base and bent forward when the animal is at rest. 'By a process analogous to that by which the common toy frogs are made to jump,' the spring-tails leap to a considerable height. The Collembola are all small, usually under a quarter of an inch in length; there are six or fewer abdominal segments; there are no compound eyes, nor hints of wings, nor metamorphosis. They usually live in damp and sheltered places—e.g. under bark or stones. Among the representative forms may be noted *Podura aquatica*, common on stagnant water in England; *Orchesella cincta*, among dead leaves and moss; *Desoria glacialis*, on the glaciers; Smynthurus; Isotoma; Macrotoma. See Sir John Lubbock, *Monograph of the Collembola and Thysanura* (Ray Society, 1873).

Spruce. See FIR.

Spruce-beer. The essence of spruce is obtained by boiling the green tops of the Black Spruce (*Abies nigra*) in water, and then concentrating the decoction by another boiling without the spruce tops. The young shoots of this fir, like most others of its family, are coated with a resinous exudation, which is dissolved in the water. Spruce-beer is made by adding the essence of spruce to water in which sugar or treacle has been dissolved, in the proportion of about four ounces of essence of spruce to ten pounds of sugar, or three quarts of treacle, and ten or eleven gallons of water, with about half a pint of yeast. Various spices are used for flavouring. A similar beverage is made largely in the north of Europe, from the buds of the Norway Spruce (*Abies excelsa*), and is known as Black Beer, that of Danzig being the most famous.

Spruner von Mertz, Karl, author of some useful historical atlases, was born at Stuttgart on 15th November 1803, joined the army of Bavaria, and taught geography in the Bavarian cadet college from 1855. His name is associated with a well-executed, and painstaking and accurate, *Historisch-geographische Handatlas*, in three parts (1853–64), embracing in all 139 maps; besides this he published historical atlases of Bavaria (1838), Austria (1860), and Germany (1866), and a few historical works dealing with Bavaria. He received the rank of General-lieutenant in 1869, and retired in 1886.

Spur, an apparatus fastened to the heel of a horseman, for goading the horse. It is much less used than formerly, and the modern apparatus, having only minute serrations on its rim, does not possess the cruel effect of the formidable spiked spurs of old times here illustrated. All cavalry soldiers wear spurs, but their use, except in the heat of an actual charge, is discouraged as much as possible. In the age of chivalry spurs were an essential ensign of knighthood, the spurs of knights (*equites aurati*) being golden or gilt, while those of squires were of silver. In the degradation of a knight—a ceremony rarely performed, but revived in effigy in the case of Lord Dundonald (1814)—one part of the proceedings consisted in hacking the spurs from his heels. Till into the 19th century knights of the shire might enter the House of Commons wearing spurs.



Various Kinds of Spurs
(From Antiquarian Museum, Edinburgh):
1, *bronze prick spur found at Linlithgow Palace*; 2, *iron spur* found near Bannockburn; 3, bronze spur found at Colchester; 4, brass spur found at Culloden, 5, spur found at Halidon Hill; 6, spur found in making a drain in High Street, Edinburgh.

Spurge (*Euphorbia*), a genus of plants of the natural order Euphorbiaceæ, having monœcious naked flowers, the male flowers membranous, and surrounding a tricoccous stalked female flower, the whole placed within a cup-shaped involucre. The fruit has three valves and three cells, the cells one-seeded, and bursting elastically. The species are very numerous, natives of warm and temperate climates, mostly herbaceous, but some of them woody. About twelve species are natives of Britain. All contain a resinous milky juice, which in most is very acrid. Several tropical species are cultivated for their great beauty in hothouses

Spurge Laurel. See Daphne.

Spurgeon, Charles Haddon, the greatest Nonconformist preacher of his day, the son of an Independent minister, was born at Kelvedon, Essex, 19th June 1834. He was educated at Colchester and Maidstone, and in 1849 became usher in a school at Newmarket, where he studied French and Greek. He narrowly escaped receiving a college training a little later, but gradually grew into his great sphere of usefulness and influence without the help of the schools. His leisure time at Newmarket was spent in religious work, and he began to give addresses in the hall of the Independent chapel. In 1850 he removed to Cambridge, connected himself with the Baptist church there which had been presided over by Robert Hall, and was received as a member of the Lay Preachers' Association. His first sermon was preached in a cottage at Teversham, about 4 miles from Cambridge. In his eighteenth year he had a call to be pastor of the Baptist chapel, Waterbeach, and soon the small congregation was doubled. In 1853 he was invited to preach in New Park Street Chapel, London, and in 1854 he was unanimously called to become pastor of the church. His sermons, which were issued in weekly numbers from the beginning of 1855, have been translated into most European languages. Growing popularity rendered the enlargement of New Park Street Chapel a necessity in 1855, and again in 1856, services being conducted first in Exeter Hall, and then in the Surrey Music Hall in the interim. A panic occurred (19th October 1856) while Spurgeon was preaching in the latter place, and when 7000 persons were assembled; seven persons lost their lives, and many were injured. At a service in the Crystal Palace, on a day of national humiliation in connection with the Indian Mutiny, Spurgeon preached to an audience of about 24,000. The vast Metropolitan Tabernacle was erected (1859–61); it cost £31,000, and has accommodation for about 6000 persons. Strangers flocked thither from all parts of the world to hear the popular preacher. In 1879 he received a pastor's silver-wedding testimonial of over £6000; a further sum of about £5000 was presented to him on his attaining his fiftieth year, all of which he devoted to benevolent schemes. In his later years he was a martyr to gout and rheumatism, and repeated attacks of illness and prostration led to his wintering in the south of France. He died at Mentone, 31st January 1892. A musical voice, clearness, directness, independence, and simplicity of style, combined with humour, common sense, a rich store of anecdote and continuous hard work, aided in keeping him in the front rank. He has been described as a 'hard-headed Englishman, full of sense, at moments so brightly expressed that it had all the effect of wit,' and of deep and genuine piety, if of narrow theology. The religious world learned with a shock of surprise in October 1887 of Mr Spurgeon's withdrawal from the Baptist Union, because no action would be taken by its leaders against persons charged with fundamental errors, whom he thought on the 'down-grade' theologically and spiritually.

Preaching was only one form of Mr Spurgeon's many-sided activity; his pen was as active as his mind and tongue, and many benevolent and useful institutions have grown up around the Metropolitan Tabernacle. The most important of these are the Almshouses, Pastor's College (1856), Stockwell Orphanage (1867), and a system of colportage, and book fund for ministers. He proved an excellent administrator, and his orphanages were models of good management. A publishing firm has found its main employment in dispersing his publications.

Mr Spurgeon, besides his weekly sermons and a monthly magazine, *Sword and Trowel* (1865), gave to the world upwards of a hundred volumes. He always preached extemporaneously, and had his notes written on a half sheet of note-paper. The text was noted on the top of the page; on the left-hand side were the subject divisions, on the right-hand side the subdivisions. His sermons, taken down in shorthand, were afterwards carefully revised by himself. The average weekly circulation of his sermons was 30,000; that on *Baptismal Regeneration* (1866) rose to 200,000. At the date of his death 2241 separate sermons and 37 volumes had been published, while there was material left to last at least twelve years longer. Besides he published *The Saint and his Saviour* (1867); the very popular *John Ploughman's Talk* (1868), which has been termed a cross between the Book of Proverbs and *Poor Richard; John Ploughman's Pictures, Treasury of David*, a commentary on the Psalms in 7 vols. (1865-80), a work upon which he was engaged for more than twenty years; *Interpreter* (1874); *Morning by Morning; Evening by Evening; Feathers for Arrows; Lectures to my Students; Commenting and Commentaries; My Sermon Notes, Salt Cellars* (Proverbs); *Flashes of Thought; Sermons in Candles* (1891); and *Messages to the Multitude* (1892). See *Metropolitan Tabernacle and its Work* (1876); *Twelve Realistic Sketches of Mr Spurgeon, Speeches at Home and Abroad*, edited by Pike (1878); Fernandez' *Nonconformity in Southwark* (1882); and Lives by Dyer, Stevenson, Pike, Walters, and Shindler (1892), which is the authorised life.

Spurn Head, a promontory stretching 2½ miles into the mouth of the Humber (q.v.), and forming the south-eastern extremity of Yorkshire. Its presence is indicated by two lighthouses with fixed lights, elevated 93 and 54 feet respectively above the sea, and visible for 15 and 12 miles, and by a light-vessel, whose revolving light is visible for 10 miles. Between 1771, when Smeaton's small lighthouse was built, and 1863 the sea gained 280 yards here, but since the erection of groynes in 1864 the land has gained. See Boyle's *Lost Towns of the Humber* (1829).

Spurrey (*Spergula*), a genus of plants which has been variously ranked by botanists in the natural orders Caryophylleæ, Illecebraceæ, and Crassulaceæ. The species are annuals, dichotomously branched, or with whorled branches; their leaves linear-filiform, in clustered whorls, with membranaceous stipules; the flowers in terminal divaricating corymbs. The flowers have a calyx of five sepals, five white petals, five or ten stamens, and five styles; the capsule is five-valved, with numerous round seeds, surrounded with a membranous border. Common Spurrey, or Yarr (*S. arvensis*), is plentiful in cornfields, especially on light stony or sandy soils in Britain and most parts of Europe. In some parts of Europe a larger variety is frequently sown for fodder, and is much relished by cattle.

Spurs, BATTLE OF. See COURTRAI, GUINEGATE.

Spurzheim, JOHANN GASPAR, one of the founders of the so-called science of Phrenology (q.v.), was born at Longwich near Treves on 31st December 1776. Whilst studying medicine at Vienna he became acquainted with Gall (q.v.), and was made a proselyte to his doctrines. The two in 1805 started on a lecturing tour through the principal countries of central Europe, and in 1807 they settled in Paris. In 1813 the two friends, their teachings disagreeing in some particulars, separated; Spurzheim proceeded (1814) to England, and lectured and wrote and laboured in the principal cities of the United Kingdom for four years, gaining a powerful adherent in George Combe (q.v.). After remaining at Paris from 1817 to 1825, Spurzheim again went back to England and renewed his propaganda, this time with much greater success. In 1832 he sailed to the United States, but died suddenly at Boston on 10th November that same year. Spurzheim advocated his doctrines with great eloquence and enthusiasm, and popularised phrenology and won for it a good deal of the attention it attracted. He wrote numerous books, including *Phrenology* (1825), *Philosophical Principles of Phrenology* (1825), *Manuel de Phrénologie* (1832); and some others on more general topics—e.g. *Elementary Principles of Education* (1821) and *Essai sur la Nature Morale et Intellectuelle de l'Homme* (1820). See Carmichael's Memoir of him (Dublin, 1833).

Spy, in War, is a useful but not highly honoured auxiliary employed to collect information and ascertain the enemy's intended operations. Spies are always used in war, and their employment is quite recognised by the law of nations as interpreted by Grotius, Vattel, and Martens; nor is it held to be any dishonour to a general to avail himself of their services. On the other hand, the spy himself is looked upon as an outlaw, and when taken is put to death ignominiously and without mercy. A spy is well paid, lest he betray his employer. In the British army spies are employed by the Intelligence branch under the quartermaster-general. In minor expeditions they are generally friendly natives. Military law, though distinct enough in ordering his death, is not clear in defining what constitutes a spy. A man, not belonging to the army, found within the lines, either in uniform or civil dress, if unable to give a good account of himself would certainly be arrested as a spy, and if anything suspicious could be proved against him would probably be hanged or shot; but if found in one camp in the uniform of the opposite side, he may not be treated otherwise than as a prisoner of war, or else as a deserter from the enemy.

Both as regards honour and penalties, it would seem that spies ought in fairness to be divided into two classes—first, those who betray their own country to an enemy (either in time of war or peace, and including persons who give foreign powers plans of fortifications, betray the construction of new weapons, &c.); secondly, those who, being enemies, contrive surreptitiously to obtain information by penetrating into the lines of the opposing army. The first class are traitors of a deep dye, for whom no ignominious death is too bad; but the second class are brave men, who dare much in the service of their country. It is unfair to accord them the same treatment as the traitors. André (q.v.) was a spy; Benedict Arnold (q.v.) was a traitor.

Civil governments, even the freest and most constitutional, do not disdain to make use, on occasion, of political spies—the most respectable use for them being the ferreting out of conspiracies and conspirators. In the days of the Tudors the political spy was a frequent and almost recognised ally of great English ministers like Burghley; in Ireland, unhappily, government has not seldom had to employ the services of Approvers (q.v.), Informers (q.v.), and also of professional spies (see Fitzpatrick, *Secret Service under Pitt*, 1892). The Secret Service Moneys (q.v.) provide for the remuneration of such persons as Le Caron of the 'Parnellism and Crime' trial in 1889, who had entered the Fenian organisation, the United Brotherhood or Clan-na-Gael, &c., and kept the government informed of all that went on in these societies. Bismarck was believed to regularly employ sham revolutionists; the second French empire had an elaborately organised system of espionage. Austria had at one time the most active agents of any European country, especially in the parts of Italy under Austrian domination. And at the present day the Russian system is the most masterful, being almost untrammelled at home, and, in the less ignoble parts of the service, represented abroad by ladies and gentlemen of great culture and high social standing. The political spy, acting in his own country, is hard to distinguish from the detective; it will often be difficult to draw a line between the spy abroad and the renegade or traitor on the one hand, and the accredited political agent on the other.

Squadron. See CAVALRY.

Squarcione, FRANCESCO (1394–1474), founder of the Paduan school of painters, best known as teacher of Mantegna (q.v.).

Square Root. See INVOLUTION.

Squares, METHOD OF LEAST, an arithmetical process of great importance for combining observations, or sets of observations, so as to obtain the most probable value of a quantity which depends on these observations. It is in fact the scientific method of taking certain averages, and it finds its most constant use in astronomy and other physical sciences. The necessity for applying the method arises from the fact that, when the greatest precision of measurement is sought, repeated measurements of the same quantity do not agree. Thus, the altitude of a star at culmination, if carefully measured night after night by the same observer through the same instrument, will in general come out a little different in the different observations. All the measurements will, however, lie within a certain range of variation; and if all are equally trustworthy, the arithmetical mean will give the most probable value of the real altitude. The differences between this mean and the individual measurements on which it is founded are called the residuals. The important mathematical property of these residuals is that the sum of their squares is less than the sum of the squares of the differences between the individual measurements and *any* other single quantity that might be taken. Now, this principle of 'Least Squares' holds not only for the simple case just described, but also for more complicated cases in which one observed quantity (y) is to be expressed as an algebraic function of another or of several independently observed quantities (x). Here the object is to find the most probable values of the assumed constants or parameters which enter into the formula. When these values are calculated we can calculate in terms of them and the observed x's a value of y corresponding to each set of observations. Comparing the calculated y's with the observed y's, we get a set of residuals, the sum of whose squares is a minimum if the parameters have been calculated according to a particular process. It is this process which is described as the method of least squares. Its basis is found in the mathematical principles of Probability (q.v.). See Professor Merriman's *Textbook on the Method of Least Squares* (2d ed. 1885), or Chauvenet's smaller treatise (1879), and for elementary discussion any good treatise on practical astronomy and geodesy.

Squaring the Circle. See QUADRATURE.

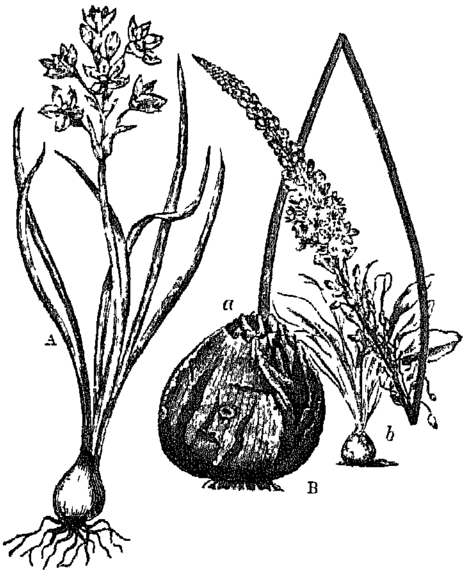
Squash, a term loosely used, especially in the United States, for two or three kinds of Gourd (q.v.), including the pumpkin.

Squid. See CALAMARY.

Squier, EPHRAIM GEORGE, American author and archæologist, was born at Bethlehem, New York, June 17, 1821. From 1841 to 1848 he was a newspaper editor, latterly in Ohio; and his attention being attracted to the antiquities of the Scioto Valley, he made an exploration of similar monuments through the Mississippi Valley, an account of which was published in vol. i. of the *Smithsonian Contributions to Knowledge* (1848). He made similar explorations in New York in 1848; and next year being appointed *chargé d'affaires* to the states of Central America, he used his official position as a means of making extensive geographical and archæological explorations in those regions. For his researches he received the gold medal of the French Geographical Society. In 1853 he surveyed a railway route through Honduras, and extended his archæological inquiries. In 1863 he was appointed U.S. commissioner to Peru; and afterwards he edited Frank Leslie's publications. He died in Brooklyn, 17th April 1888. Among his works are *Nicaragua: its People, Scenery, and Ancient Monuments* (1852); *Serpent Symbols* (1852); *Notes on Central America* (1854); *Waikna, or Adventures on the Mosquito Shore* (1855); *Central America* (1857); and *Peru: Explorations in the Land of the Incas* (1877).

Squill (*Scilla*), a genus of bulbous-rooted plants of the natural order Liliaceæ, with radical leaves, and flowers in terminal racemes or loose corymbs. The species, which are numerous, are natives chiefly of the Mediterranean and Caucasian regions. Three are natives of Britain, *S. verna*, which is abundant on the east coast of Ireland, the west and north coasts of Scotland, more sparingly on the east coast of Scotland, and very locally in north-eastern England; *S. autumnalis*, which is confined to some of the southern counties of England; and *S. nutans*, the wood-hyacinth or blue bell of England, which is very abundant in most parts of Great Britain and Ireland. These and many exotic species are frequently cultivated for the sake of their beauty in British gardens.

Very different in habit from these, and now separated from the genus, is the Officinal Squill (*Urginea Scilla*, or *maritima*; formerly called *Scilla maritima*), a native of the sandy shores of the Mediterranean, which has a scape from two to four feet high, with a raceme of many whitish flowers and large leaves. The bulb is of the size of a man's fist, or sometimes as large as a child's head, and contains a viscid juice so acrid as to blister the fingers if much handled, whilst the vapour arising from it irritates the nose and eyes.



A, *Scilla verna*; B, Officinal Squill (*Urginea Scilla*): *a*, plant with flowering scape in blossom; *b*, plant with full-grown leaves. (From Bentley and Trimen.)

Squill was used in medicine by the ancients, and is still largely employed. The bulb is dug up in autumn, divided into four parts, the centre being cut out as being inert, and the remainder being cut into thin slices, which are quickly dried by a gentle heat. The dried slices are white or yellowish white, slightly translucent, odourless, disagreeably bitter, brittle, and easily pulverisable if very dry. The bulb contains a number of active principles, the chief of which is a glucoside, *scillain*, having much the same action as digitalis; other active ingredients have been described under the names *scillitoxin*, *scillin*, and *scillipicrin*. This medicine is prescribed as a diuretic and expectorant, and occasionally as an emetic; but it must be recollected that in moderately large doses it acts as a narcotico-irritant poison, twenty-four grains having proved fatal. When given as a diuretic it is usually prescribed in combination with digitalis and calomel, when it seldom fails to produce an increased secretion of urine, and thus promotes the absorption of the dropsical effusion which is generally present when diuretics are ordered. Its dose as a diuretic is from one to three grains of the powdered bulb, or about twenty minims of the tincture. As an expectorant it is much employed in the subacute stages and chronic forms of pulmonary affections, and is very serviceable in bronchitis and pneumonia of children. From its property of promoting the secretion of mucus, it gives relief by facilitating the expectoration in cases of asthma, &c., in which the sputa are viscid. In these cases it is usually prescribed with some of the more stimulating expectorants, as carbonate of ammonium. As an expectorant the dose of the powdered squill should not exceed one grain, repeated several times daily. For children the syrup, in doses of from ten to thirty minims, may be given. As its action as an emetic is uncertain and dangerous, it should not be prescribed with the view of inducing vomiting.

Squilla, a genus of Crustaceans, representative of the order Stomatopoda. The members are sometimes called *Mantis Crabs* or *Mantis Shrimps*, from the slight resemblance to the insects of the genus Mantis (q.v.). The body is slightly flattened; the carapace does not completely cover the thorax; the pincers of the large anterior forceps are formed by the last joint closing on the second last; the gills are borne by the first five pairs of abdominal appendages; the last pair of abdominal appendages form a broad tail fin. The species are numerous, especially in tropical seas. They are active, voracious crustaceans, fond of burrowing in the mud; they are often very brightly coloured; the young forms undergo a marked metamorphosis, which has not been completely followed.

Squint, or HAGIOSCOPE, a narrow aperture cut in the wall of a church (generally about two feet wide), to enable persons standing in the side-chapels, &c. to see the elevation of the Host at the high altar.

Squinting (technically, *Strabismus*) is a well-known and common deformity, which may be defined as a want of parallelism in the visual axes, when the patient endeavours to direct both eyes to an object at the same time. It may be due to loss of power (paralysis or paresis) of one or more of the eye muscles; and this may depend on a merely local affection, or may be a symptom of serious brain disease. But in the majority of instances, and in all ordinary cases of squint (to which this article will be confined), no such condition is present. The squint is said to be *convergent* when the squinting eye is directed towards the nose, and *divergent* when it is directed towards the temple; the convergent is much the more common. Misdirection of one eye upwards or downwards is of rare occurrence. Only one eye can squint at a time; but if sometimes one eye and sometimes the other is misdirected, the squint is said to be *alternating*; if always the same eye, *monocular*.

Convergent squint usually comes on during childhood, most often from the second to the seventh year. If present at birth it is caused by some serious defect in the muscles. It is sometimes due to defective sight in the squinting eye, from congenital abnormality, severe inflammation, or injury; but very often no such condition is present. In a large proportion of cases it is accompanied by *hypermetropia* (see EYE, p. 515), and is due to the increased effort of accommodation required to see near objects, being associated with an increased and disproportionate effort of convergence. In such cases, if suitable glasses can be worn as soon as the squint begins to show itself, it may be prevented from becoming permanent. It is but seldom, however, that the surgeon is consulted at a sufficiently early stage for this treatment to have a fair chance to succeed, and even at an early stage it is by no means certain to prevent the development of a squint. In other cases the presence of a squint may be traced to the presence of worms, the irritation of teething, &c.; and it disappears when the cause is removed.

Divergent squint is very rarely present without considerable defect in the sight of the squinting eye, except where it is the result of over-correction of a convergent squint by operation. It is often associated with myopia, as the other form is with hypermetropia. When the vision of one eye is damaged by disease or injury in the adult, and takes a faulty position in consequence, divergence is much more common than convergence; in children, as has been said, the latter is the usual result.

The surgical operation for the correction of a squint consists in the division of the muscle whose excessive activity leads to the faulty position—in convergent strabismus the internal rectus, in divergent the external. It is often necessary to operate on both eyes in the same manner, even where the squint is monocular. In some cases it is requisite in addition to shorten the opposing muscle (i.e. in divergent strabismus, where this procedure is most often resorted to, the internal rectus).

Squire, an abbreviated term for Esquire (q.v.). The same word is also popularly applied in England to country gentlemen; and in the United States to local judges, justices of the peace, or other dignitary of the place.

Squirrel, the vernacular name of the *Sciurus vulgaris*, and in a wider sense of all members of the sub-family Sciurinæ. These are characterised by their slender body, cylindrical hairy tail, and large prominent eyes; the ears are of variable size—often tufted; anterior limbs shorter than posterior, the former have four fingers and a rudimentary thumb, the latter five complete toes. Their habits are for the most part arboreal; some few excavate subterranean retreats. Their distribution is cosmopolitan, excluding the Australian region. There are seven recent genera and several fossil ones. (1) Sciurus, in addition to the characters of the family above mentioned, has the tail long and bushy, ears pointed—often tufted, the digits with long, curved, sharp claws, skull delicate, with long post-orbital processes, penultimate upper premolar, when present, minute. *S. vulgaris*, the common squirrel, measures 18 inches long (including the tail, which is 8 inches), and weighs about half a pound; its colour in summer is brownish red above, mixed with gray on the side of the head, white below from the chin; in winter the brownish red above becomes mixed with grayish hairs, whilst in Siberia and northern Europe generally the whole animal becomes whitish gray without a trace of red; black varieties occasionally appear. It occurs at the present day all over the palæarctic region, from Ireland to Japan and from North Italy to Lapland, whilst its remains occur as far back in the geological history as the 'Cromer Forest Bed.' In Scotland it bade fair to become extinct, but with the planting of new woods in the later half of the 18th century it has again spread rapidly, so much so as in places to become a great nuisance. Its favourite dwellings are dry and shady woods, especially of beech and oak, whose nuts furnish it with a winter food-supply. It is always in motion, and in fine weather may be seen skipping from tree to tree as if in pure enjoyment; on the ground its pace is so rapid that a dog can scarcely catch it, but it is still more at home among the branches, where its sharp claws enable it to cling safely to the smoothest bark. When undisturbed it seems to be constantly on the lookout for food, which, if abundant, is stored up for future use; and, according to Radde, it is so altruistic as to impale fungi on the tips of branches so that any passing squirrel in need may share them. It eats berries, nuts, buds, occasionally a beetle or two, and is a greedy and successful plunderer of birds' nests; it does great mischief in the spring by nibbling the fir-buds and gnawing the bark, the rising sap being apparently specially palatable to it. Soft fruit does not seem to be much appreciated, the flesh of apples and pears being discarded in favour of the pips. The squirrel will use a bird's nest for a temporary lodging, but the home is always constructed afresh, though the materials collected by others may be utilised. The nest is usually situated in the fork of a branch near the stem, and has a roof to keep out rain, a main entrance opening downwards, and a smaller accessory opening near the stem. The squirrel lies curled up when asleep, is very sensitive to the weather, and even seems to be prescient of storms. It swims freely on occasion. Pairing takes place in March, when there are often savage fights between the males; four weeks later from three to seven young are born, which remain blind for about nine days; for five days or so after the young leave the nest the whole family sports together among the trees, and then breaks up; in June there is a second brood, which may occasionally be seen in company with the former one. In winter the squirrel hibernates, awaking from time to time to feed on its stores. Its chief enemy is the marten, which is much stronger and climbs equally well, though it cannot take such leaps from tree to tree. The fur of the squirrel has a commercial value. On the Lena trapping it furnishes occupation for many hands, some hunters having as many as 1000 snares; Russia and Siberia yield six or seven million skins per annum, valued at £150,000, but the best Siberian skins fetch as much as 1s. 6d. The genus includes between seventy and eighty other species, some of those from the Oriental region being very highly coloured; in one of them (*S. caniceps*) the back becomes of a bright orange colour during the breeding season, a rare phenomenon among mammals. (2) Pteromys includes the Taguan or Flying Squirrel (*P. petaurista*), the largest of the sub-family, being nearly as large as a cat; see FLYING ANIMALS. (3) Rhithrosciurus is a large squirrel from Borneo, with black and white striped sides and grooved incisor teeth. (4) Tamias is an American genus, though one species extends into Asia and even to eastern Europe. All the four species have cheek-pouches, and the back is ornamented with darker and lighter stripes; see CHIPMUNK. (5) Xerus includes the so-called 'Spiny Squirrels,' of which there are four species, all African; the fur is coarse, the claws straight, and the external ear small or absent. They inhabit the dry steppes, and dig holes in the roots of trees or among rocks. The Prairie Dog (q.v.) was sometimes called the 'Barking Squirrel.' See J. A. Harvie-Brown's *History of the Squirrel in Great Britain* (Edin. 1881).

Common Squirrel (*Sciurus vulgaris*).

Squitch. See COUCH-GRASS.

Srinagar, or CASHMERE, the capital of the native state of Cashmere in Northern India, stands in a lovely valley of the Himalayas (besung by Moore in his *Lalla Rookh*), on both sides of the Jehlam (Jhelum), at an elevation of 5276 feet. Its appearance and situation are described under CASHMERE. Pop. (1891) 120,340.

Srirangam. See SERINGHAM.

St. For places named after saints (St Albans, &c.), see at SAINT, pp. 80–101.

Staal, MARGUERITE JEANNE, BARONESS DE, usually distinguished from the greater Mme. de Staël-Holstein as Madame de Staal-Delaunay, was born at Paris, May 30, 1684, the daughter of a poor painter named Cordier, whose name she dropped for that of her mother, Delaunay. She had a sound education at the convent of Saint Louis at Rouen, and at twenty-seven was attached to the person of the imperious and intriguing Duchesse de Maine at the little court of Sceaux. Here she saw before her eyes all that comedy of life which she was later to describe with such penetrating insight. Her position was at first a servile one, and she must often have been sorely tried by the temper of her mistress, but in herself remained not one whit of what she calls the 'caractère indélébile de femme de chambre,' and all her life was ruled in harmony with her own words, that it is only our own actions which can degrade us. Her devotion to the interests of the Duchesse brought her two years in the Bastille, where she had a love affair with the Chevalier de Menil. In 1735 she married the Baron de Staal, an officer of the Guard. She died at Paris, 16th June 1750. Her *Mémoires* (4 vols. 1755; eds. by Barrière, 1846; Lescure, 2 vols. 1878) show intellect and observation, as well as remarkable mastery of subtle irony, and are written in a style clear, firm, and individual. 'Je ne me suis peinte qu'en buste,' she says, by which must not be understood that this lofty soul and admirable writer was ever consciously or unconsciously untrue. For indeed sincerity is her first characteristic, and throughout she reflects things like a mirror, without addition, omission, or distortion. 'Le vrai est comme il peut, et n'a de mérite que d'être ce qu'il est.' Her *Œuvres Complètes* appeared at Paris in 2 vols. in 1821. See the study by Frary (1863), and Sainte-Beuve, *Portraits Littéraires*, vol. iii.

Staaten Island. See STATEN ISLAND.

Stabat Mater, a celebrated Latin hymn on the seven dolours of the Blessed Virgin, whose authorship has been assigned to Jacopone da Todi, a Minorite who flourished in the 13th century. It has been set to music by many composers of eminence—e.g. Palestrina, Pergolese, Astorga, Haydn, and Rossini. See Lisco's monograph (Berl. 1843).

Stability, the name given to the property possessed by all material systems whose configuration remains permanent or never departs far from a permanent average type. There are two kinds—static and kinetic. Of static stability, or stable equilibrium, we have numerous examples of a simple character. A pendulum or any body hanging under the influence of gravity by a point which is not its centre of mass; a ball resting inside a basin; any object resting on supports in such a way that a vertical line through its centre of mass falls well within the polygon formed by joining the points of support—all these are familiar instances. If any displacement (within certain limits) is given to the body, it will, when released, tend to recover its original condition. In dynamic language the forces brought into play by the displacement resist it. If, however, the ball is placed on the top of a convex surface, or if a chair, for example, is tilted until the vertical line through its centre of mass falls outside the original area of its base, then the configuration is no longer stable. Both bodies will fall away from these positions until a new configuration of stable equilibrium is reached. In general, stability is proved by a system recovering its configuration after a slight displacement. Instability is demonstrated when any slight displacement is followed by a complete change of configuration, forces being brought into existence which assist the displacement. When a displacement brings into play no forces, so that the system tends neither to recover nor to fall away from its original configuration, the equilibrium is said to be neutral or labile. A uniform sphere resting on a plane is a simple example of this kind of equilibrium.

In kinetic stability, or stability of steady motion, a new factor comes into play. Neither a spinning-top nor a bicycle can rest upright unless it is in more or less rapid motion. The moon would fall into the earth, and the earth into the sun, if it were not for the orbital velocity sustaining each in its path. The perturbations produced by the planets cause the earth to be constantly deviating from its mean orbit; yet in virtue of kinetic stability this deviation is never large, and takes place now in one direction, now in another. If no frictional effects existed in the solar system, all the planetary orbits would never vary beyond certain assignable limits.

Stables. See HORSE, Vol. V. p. 795.

Stachys, a genus of plants of the natural order Labiatæ, containing a great number of species, mostly European, having a ten-ribbed calyx, with five nearly equal teeth, the upper lip of the corolla entire, and the lower lip three-lobed. Several species are natives of Britain. *S. sylvatica* is very common in shady places, a coarse herbaceous plant, sometimes called *Hedge Nettle*, with stem two to three feet high, ovate heart-shaped leaves on long stalks, whorls of purple flowers, and unpleasant smell. *S. palustris* is another very common British species, growing in moist places, and sometimes proving a very troublesome weed in meadows. The plant was formerly used as a vulnerary, and has therefore the English name *Woundwort*. Several species are not unfrequently to be seen in flower-gardens. To this genus some botanists refer the Common Betony or Wood Betony (*S. betonica*, or *Betonica officinalis*), plentiful in woods and thickets in the southern parts of Britain, a plant one or two feet high, with hairy stem, oblong heart-shaped leaves, whorls of purple or white flowers, and a fetid smell. It was formerly much used in medicine. The roots, in small doses, are emetic and aperient.

Stade, an ancient town of Hanover, near the mouth of the Schwinge, a tributary of the Elbe, 2 miles W. by N. of Hamburg. There are large brick-works. Pop. 9997. The *Stade Dues* were a toll charged by the Hanoverian government on all merchandise carried up the Elbe to Hamburg. First formally recognised in 1691, they gradually increased till they brought a revenue of £40,000 a year. They were abolished in 1861, Hanover receiving £428,600 as compensation, of which Britain and Hamburg contributed each £155,555.

Stadium, the course on and over which the foot-races were run at Olympia and other places in Greece. It was oblong in shape, and 631 feet long. Seats were provided overlooking the course for more than 40,000 spectators. Besides foot-races, leaping, discus-throwing, wrestling, and other sports were celebrated on the same racecourse. The stadium at Athens, levelled and laid out by the orator Lycurgus in the first half of the 4th century B.C., was 600 feet long by 130 wide, and its seats could accommodate as many onlookers as those at Olympia. The length of the Olympian stadium was adopted as the Greek standard measure of length or distance. Seven and a half stadia, or 4732 English feet, were reckoned as equivalent to a Roman mile, at least in the time of the empire.

Stadtholder, a barbarous English form of the Dutch *Stadhouder*, 'stead-holder,' of which the French *lieu-tenant* is a literal translation, *Statthalter* being the corresponding German. The word, as usually written in English, suggests quite falsely that it is connected with the German word *Stadt*, 'a city.' The title of Stadhouder (i.e. royal lieutenant or viceroy) of the provinces Holland, Zealand, and Utrecht was in defiance of the rights of these provinces conferred in 1540 on a foreigner, René, Prince of Orange, at whose death (1544) it passed to his cousin, William the Silent. In 1559 there were in the Low Countries eight other Stadhouders of provinces, or groups of provinces, besides the Prince of Orange; all were commanders-in-chief of their provinces, and all except Count Egmont were also supreme civil and criminal judges. In Brabant there was no Stadhouder other than the Regent. After the United Provinces had thrown off the yoke of Spain (see HOLLAND, Vol. V. p. 742) this title, now grown dear, was retained (though a misnomer) for the head of the republic, and became hereditary in the House of Orange until superseded by the title of king.

Staël, MADAME DE, one of the most illustrious of Frenchwomen, was born at Paris, 22d April 1766. Her full name was Anne-Louise-Germaine Necker, and she was the only child of Necker and his irreproachable but colourless wife, who as Suzanne Curchod had loved the young historian Gibbon at Lausanne. Germaine was an extraordinarily precocious child, figured at receptions at eleven, and grew up in an atmosphere of admiration. She ever loved and respected her mother, but her father throughout life she loved on this side idolatry. Rousseau, Clarissa, and Werther were her first idols, she was steeped in the sensibility of the age, and already in her girlhood she wrote romantic comedies, tragedies, novels, essays, and one book which has lived, *Lettres sur Rousseau* (1789). She was fifteen when her father was dismissed from office for publishing his famous *Compte Rendu*, and withdrew into retirement, carrying with him the admiration of the whole of France. A great marriage was desired for the young heiress, and it seems certain that William Pitt on his visit to the Continent in 1783 was a suitor for her hand, and one favoured especially by her mother, although displeasing to herself. At length after long negotiations she married on January 14, 1786, the Baron de Staël-Holstein, whom Gustavus III. of Sweden pledged himself to retain as his ambassador at Paris. He was drowned in debt, and seventeen years her senior, but proved an inoffensive and easy husband. She bore him two sons (1790 and 1792) and a daughter (1797), but to protect her fortune separated formally from him in 1798, although she hastened dutifully to his bedside when he died four years later. The deepest feeling of her heart was a woman's craving for love, and those who can read between the lines of *Delphine* (1802)—the real romance of her life—will understand how little she had realised her youthful dream in marriage. But hardly less deep within her heart was the desire to shine and to please, and this she gratified to the full as a society-queen in the brilliant world of the Paris of her day. She lacked the special charm of beauty, she was careless of dress, impulsive and abrupt in manners, but her vast capacity for enthusiasm and the passionate intensity of her affections gave force and colour to her rich and versatile character, and combined to form a personality whose influence was irresistible. Society and conversation were a necessity of her nature, and called forth from the depths of her heart that flowing impromptu eloquence that subdued all hearers into admiration. The simplicity and directness of her thought was no less remarkable than its impetuosity and force, and words and ideas flowed from her lips in a kind of glorified improvisation that suggested at once the exalted inspiration of the prophet, the refined sensibility of the woman, and the clear understanding of the thinker. 'Were I queen,' said Madame de Tessé, 'I would order Madame de Staël to talk to me for ever.'

She shone brilliant and solitary in Paris, but many envious enemies—her father's before her own—embittered her triumph. Meanwhile the dawn of revolution promised to open up new horizons for France, but events moved quickly to their inevitable end, and Necker's elevation and unregretted fall but hastened on the dénouement of the tragedy. She mistrusted Mirabeau, and saw with sinking heart the ruin of the monarchy, but only quitted Paris for Coppet at the last moment, in September 1792. Indeed she risked her own life with characteristic unselfishness to save some of her friends, and only fled when it was impossible longer to remain. From Coppet she went to England, where at Mickleham in Surrey she was surrounded by Narbonne, Talleyrand, Montmorency, Lally, and Malouet, and cast her unfailing spell over that warm-hearted little prude Fanny Burney. Even here, victim of the Revolution as she was, Necker's daughter was shunned by the royalist exiles; still with all her mortifications she acknowledged that she owed to England 'four months of happiness saved from the shipwreck of life.' She joined her husband at Coppet in May 1793, and launched into the world her *Réflexions sur le Procès de la Reine* in the vain hope to save the head of Marie Antoinette. The Terror literally crushed her sympathetic heart, and all work became for a time impossible. Her mother died in May 1794; in September of the same year she found some consolation in a new friendship with Benjamin Constant, which formed an epoch in the lives of both. In May 1795 she returned to Paris, where her husband had re-established himself as ambassador. She prepared for a political rôle by her *Réflexions sur la Paix intérieure* (1795), and published some of the novels of her youth, with an *Essai sur les Fictions*, but the Directory found her inconvenient as a citizen of Paris, and she was advised to return to Coppet in December. Her book *De l'Influence des Passions* appeared in the autumn of 1796; the chapters on ambition and suicide are forced and feeble; those on woman's love, unsatisfied, misunderstood, betray the living heart. She was allowed to return to Paris in April 1797. The young conqueror, Bonaparte, overawed her with a vague presentiment of fear. He disliked clever women, and received her friendly advances with such studied coldness that their mutual feelings soon turned to hatred. In April 1800 she published her famous book *De la Littérature considérée dans ses Rapports avec les Institutions sociales*—a thesis of 600 pages on that perfectibility of the human mind which finds its consecration in the liberty guaranteed by republican institutions.

She returned again to Paris in March 1802, when her salon was more brilliant than ever. Here the vulgarity and charlatanism of the Napoleonic régime were heartily laughed at, but at length the epigrams of Constant, her own friendship with disaffected men like Moreau and Bernadotte, and last of all the appearance of Necker's *Dernières Vues de Politique et de Finances* exhausted the patience of Napoleon. And now commenced that ten years' duel between Cæsar and a single woman of genius, which drew towards her the pity and admiration of the world. If she does pose somewhat too complacently throughout as the victim of a tragedy, and if there is still something of theatrical exaltation in her exile's despair, it cannot be denied that Napoleon belittled himself by his malignant and spiteful persecution. Already in 1802 her friends fell off from her under Napoleon's displeasure, and in the autumn of 1803 she received orders to keep forty leagues from Paris. Her husband had died in May 1802, and she was now free to marry Constant, but she determined not to convert a slave into a master, and in December 1803 set out with her children for Weimar. Schiller received her with warmth, but Goethe paid a more unwilling homage. She dazzled the whole court with the extraordinary volubility and force of her ideas, yet even the generous Schiller breathed a sigh of relief when she departed for Berlin. Here she made acquaintance with the erudite August Schlegel, afterwards to be added to the circle of intimates at Coppet to the displeasure of Sismondi, Bonstetten, and the rest. She next turned her steps towards Vienna, but on the way learned of her father's death, and at once returned to Coppet, her heart weighed down under the deepest grief of her life. She found relief during the spring in writing the sincere and touching eulogy, *Du Caractère de M. Necker et de sa Vie privée*. Then she set out for Italy accompanied by Schlegel, Wilhelm von Humboldt, and Bonstetten, and returned to Coppet in June 1805 to write *Corinne*, a romance unfolded in a journal of travel mingled with meditations on history, the heroine again herself, exalted indeed, but recognisable down to close personal traits. It at once brought her a European fame, and it revealed to Frenchmen all the mystery and charm of Italy.

She visited Germany again in the end of 1807, thought for a moment of travelling in America, and about this time began to turn for consolation to religion, or at least to what the Duc Victor de Broglie terms with a happy and pious vagueness, 'un latitudinariste piétisme.' Her famous book *De l'Allemagne* was finished in 1810, submitted to the established censorship, and then entrusted to the same publisher who had printed *Corinne.* To see it through the press she established herself at Chaumont, and ten thousand copies had already been struck off when the whole was seized by Savary and destroyed, and herself ordered instantly to Coppet. It was the crowning act of Napoleon's malignity, but fortunately her son had preserved the manuscript, and at length the work was safely published by John Murray at London in 1813. But her exile had now become a bitter reality, and she found herself encompassed with spies, the postmasters between Coppet and Geneva forbidden to supply her with horses, and her faithful friends, Montmorency, Schlegel, Madame Récamier, and others exiled or imprisoned for visiting her. Overwhelmed with despair, she escaped secretly to Berne, and thence made her way through Innsbruck, Vienna, and Galicia to Russia, then to St Petersburg and Stockholm, and finally in June 1813 to London. The progress of the enemy of Napoleon through the northern capitals was a continuous triumph, and in England she found herself the object of an unbounded admiration that reached its climax in the enthusiasm which followed the publication of *De l'Allemagne*, the most finished of all her works. She made acquaintance with Lord Grey, Lord Lansdowne, Sir James Mackintosh, Lord Holland, Canning, Wilberforce, and Byron. The last, while acknowledging his admiration for the writer, has not spared some characteristic sneers against the woman. The autumn of 1814 found her again at Paris. She was received with the utmost cordiality by Louis XVIII., but it sickened her patriotic heart to see that French freedom was the work of strangers whose foreign uniforms darkened the streets of Paris. Her old friends flocked to her salon; Madame Récamier, Madame de Krüdener, and Benjamin Constant, already twice married, disillusioned, and forty-eight years old, but still in love with her, although her own feeling had long subsided into quiet affection; even the time-serving Talleyrand, who had so long forgotten his early friendship, was generously forgiven. She returned for the summer to Coppet, but spent the winter of 1814–15 again at Paris, where the two millions which Necker had left in the Treasury was honourably paid back to her. The escape of Napoleon from Elba drove her hurriedly from Paris, and after Waterloo she did not return to witness the humiliation of the second occupation. She spent the winter in Italy for the sake of the health of Albert de Rocca, whom she had met about the end of 1810 at Geneva, and married secretly, though twenty-one years his senior, in the beginning of 1811. Her daughter Albertine married the Duc Victor de Broglie in February 1816. Her own health now began to give way, but she forgot her sufferings in the devoted affection of her husband, himself in enfeebled health and destined for an early grave. She died without pain on the morning of 14th July 1817, and was buried at her father's feet at Coppet. Her surviving son and daughter made public the marriage with Rocca, and received as a brother the son she had borne him. They published with pious care in 1818 her unfinished *Considérations sur la Révolution Française*, which Saint-Beuve thought her finest work, and in 1821 the *Dix Années d'Exil.*

A complete edition of her works was issued by her son, the Baron Auguste de Staël (17 vols. 1820–21), with a Notice by her cousin, Madame Necker de Saussure.

Madame de Staël has not maintained the place unanimously given her by her contemporaries and her immediate posterity, but she still remains as a woman and a writer a unique phenomenon in the history of letters. She had little creative power, was careless of style, and was steeped in a sensibility long since happily forgotten; but her remarkable personality can never lose its attraction, and her work remains entire in its influence on the one side on Royer-Collard, Guizot, and the Doctrinaires, and on the other on Lamartine and the whole Romantic movement in France. She has given an endless subject to the ablest critics of France from her own day down to Sainte-Beuve, who says in one of his latest writings (1862), 'she has been one of the idols of my youth, and that idolatry I have not abjured.'

See the elaborate Lives by Stevens (2 vols. Lond. 1880), Lady Blennerhassett (3 vols. Berl. 1887–89; Eng. trans. 3 vols. 1889), and the shorter studies by Bella Duffy (1887) and Albert Sorel (1890; Eng. trans. 1892). See also Gérando, *Lettres inédites et souvenirs biographiques de Mad. Récamier et de Mad. de Staël* (1868), and the Comte d'Haussonville's book, *Le Salon de Madame Necker* (2 vols. 1882; Eng. trans. 1882). Criticisms will be found in Sainte-Beuve's *Portraits de Femmes*, and in the collected studies of Caro, Scherer, Brunetière, &c. Her husband's *Correspondance diplomatique* was published at Paris in 1881.—The famous estate of Coppet, bequeathed by Necker to Madame de Staël, and lastly the property of her granddaughter, Madame d'Haussonville, sister of the Duc de Broglie, was sold by her in 1880.

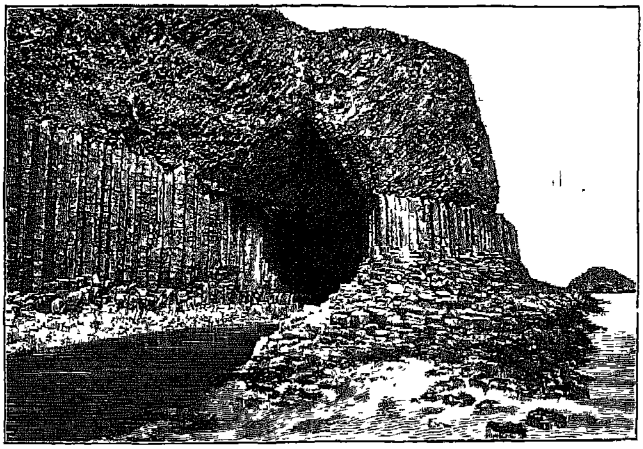
Staff, in a Military sense, consists of a body of skilled officers, whose duty it is under orders from the commanding officers of various grades to arrange the movements and supply of the various bodies which go to make up an army. Regimental officers deal personally with the men under their command. Staff officers deal only with the commanders of the larger units into which the troops are grouped for tactical or administrative purposes. Thus, in arranging the march of an army corps, the officers of the *Army Corps Staff* would, amongst other things, allot the available roads to the three divisions and other troops, &c. The officers of each *Divisional Staff* would direct the order in which their brigades, &c. would move along those roads. The *Brigade Staffs* would give more detailed orders, perhaps telling off the battalions required to form the advanced guards; while the *Regimental Staffs* of these battalions would order the actual formation to be assumed by them under the command of their *Regimental Officers* (captains and lieutenants). Artillery and Engineer duties, Supply and Transport for each unit are managed in a similar way. On the staff of each army corps and division there is a representative of the Artillery, Engineers, Army Service Corps, Medical Staff, Ordnance Store Corps, Veterinary and Pay Departments, Chaplains, Post office, and Military Police. A good staff is all-important to the success of a military enterprise.

The *General Staff* of an army comprises the general in actual command, with the subordinate generals commanding the several divisions and brigades; the assistants to these—viz. the officers of the adjutant-general's department—i.e. the adjutant-general, his deputy, assistants, and deputy-assistants; the officers of the quartermaster-general's department; the brigade-majors; the provost-marshal; and the judge-advocate—the functions of all of whom are described under their respective heads. The head of the general staff of the British army is the adjutant-general at the War Office. India forms a nearly independent command, under a commander-in-chief, whose headquarters are in Bengal. There are subordinate commanders-in-chief in Bombay and Madras; and in each presidency there are several military divisions. Every general in command of a district or body of troops has a staff consisting of representatives of the adjutant-general's department and of the other services. An officer before he can be appointed to the general staff must have passed the Staff College or become qualified for the staff by having been employed as a staff officer with a force on active service, except in India, in which case he must belong to the Indian Staff Corps. Officers of the Army Service Corps also are now appointed to the general staff at home. The *Personal Staff* consists of the aides-de-camp and military secretaries to general officers. These officers are appointed, within certain limits, by the generals whom they serve. The *Regimental Staff* of a battalion of infantry or regiment of cavalry consists of the lieutenant-colonel commanding, the adjutant, quartermaster, surgeon, veterinary surgeon, and transport officer.

Staff Corps—During the wars of Wellington the generals and staff officers were aided by a staff corps composed of intelligent officers and men who performed engineering and siege duties, made reconnaissances, and executed other necessary labours for which regimental officers or soldiers were unsuited. This corps died out after the peace. British officers serving on the permanent Indian establishment join what is called the Indian Staff Corps, and are appointed from it to do duty with native regiments, or to fill other positions either military or civil. Their promotion goes on according to length of service.

In the Navy the staff of a fleet consists of the Flag-officers (q.v.), the Flag-lieutenants (q.v.), and Secretaries (q.v.); also of the inspector-general of hospitals (see ARMY, p. 438; NAVY, p. 422), and an inspector of machinery.

Staffa (Scand., 'pillar-island'), a celebrated islet on the west of Scotland, lies 4 miles SW. of Ulva, 6 N. by E. of Iona, and 54 W. of Oban. It forms an oval uneven tableland, rising at its highest to 144 feet above the water, 1½ mile in circumference, and 71 acres in area. In the north-east, in the lee of the prevailing winds, is a tract of low shore, stretching out in beaches, and forming a landing-place; but elsewhere the coast is girt with cliffs from 84 to 112 feet high. Regarded in section, the rocks show themselves to be of three kinds—conglomerated tufa, forming the basement; columnar basalt, arranged in colonnades, which form the façades and the walls of the chief caves; and amorphous basalt, overlying the columnar basalt, but pierced here and there by the ends of columns and by angular blocks. The most remarkable feature of the island is Fingal's or the Great Cave, the entrance to which is formed by columnar ranges on each side, supporting a lofty arch. The entrance is 42 feet wide, and 66 feet high, and the length of the cave is 227 feet. The floor of this marvellous chamber is the sea, which throws up flashing and many-coloured lights against the pendent columns, whitened with calcareous stalagmite, that form the roof, and against the pillared walls of the cave. First described (in Pennant's *Tour*) by Sir Joseph Banks, after a visit in 1772, Staffa has since been frequently visited—among others by Wordsworth, Scott, Mendelssohn, and, on 19th August 1847, Queen Victoria.



Fingal's Cave, Staffa.

Staff College. See MILITARY SCHOOLS.

Stafford, the county town of Staffordshire, on the left bank of the Sow, 3 miles above its junction with the Trent, and 25 miles SSE. of Crewe, 29 NNW. of Birmingham, and 133 NW. of London. St Mary's Church, formerly collegiate, is a good cruciform structure, with an octangular tower. *Transition Norman to Decorated in* style, it was restored by Scott in 1844–47 at a cost of £30,000, and in 1878 received a bust of Stafford's chief worthy, Izaak Walton, who was baptised in its font. St Chad's, Norman, was very thoroughly restored during 1855–85; and there are also King Edward's grammar-school (1550; rebuilt 1862), the town-hall (1798), a free library (1882), the William Salt Library (1874), the Clement Wragge Museum, the infirmary (1766), the county lunatic asylum (1818), &c. Stafford Castle, finely situated on an eminence outside the town, which commands a magnificent view, is an unfinished castellated pile. It was built by Sir G. Jerningham in 1810–15, successor to a Saxon fortress of the Princess Ethelfleda, and to a later Norman stronghold, which was finally taken by the parliamentarians in 1643, and demolished. Boot and shoe making is the staple industry, and Stafford is an important railway centre. Chartered by King John, it returned two members from Edward I.'s reign till 1885, when the representation was reduced to one and the parliamentary boundary extended. Pop. (1851) 11,829; (1871) 14,437; (1891) 20,270. See works by J. Masfen (1852) and J. L. Cherry (1890).

Stafford, WILLIAM HOWARD, VISCOUNT (1614–80), a Roman Catholic nobleman, beheaded on Tower Hill as a victim of the perjuries of Titus Oates (q.v.).

Staffordshire, a west midland county of England, bounded by Cheshire, Derbyshire, Leicestershire, Warwickshire, Worcestershire, and Salop. Measuring 54 by 35 miles, it has an area of 1169 sq. m. or 748,433 acres. The only hilly district is in the north, where the wild 'Moorlands,' the southern extremity of the Pennine range, extend from north-west to south-east in long ridges, separated by deeply-cut valleys, and subside as they near the valley of the Trent. Several points exceed 1500 feet above sea-level, but Axe Edge Hill (1756) falls just within Derbyshire. The rest of the county is gently undulating, with the low upland of Cannock Chase in the centre. The Trent, flowing first south-eastward through the interior, and then north-eastward along the Derbyshire border, is the chief river, and receives the Sow, Tame, Blythe, and Dove. New Red Sandstone occupies nearly three-fourths of the total area; and in the north and south are the Pottery and Dudley coalfields, which, besides containing nearly 600 collieries, yield also (especially the northern one) vast quantities of ironstone (see IRON, Vol. VI. p. 216). The climate is cold and humid, with a rainfall of 36 inches; and, though more than four-fifths of the area is arable, much of the soil is cold and clayey, and agriculture is in rather a backward condition. In the 'Potteries' of North Staffordshire, embracing Stoke-upon-Trent, Etruria, Hanley, Burslem, &c., most extensive manufactures of china and earthenware are carried on (see Vol. VIII. p. 367); and in the 'Black Country' in the south, with Wolverhampton and Walsall, iron is very largely manufactured in all its branches. The Burton breweries are world-famous. There is a perfect network of railways and canals. Staffordshire, which is mainly in the diocese of Lichfield, contains five hundreds and 247 parishes. There are 100 county councillors, and for parliamentary purposes the county has been divided since 1885 into seven divisions, each returning one member—Leek, Burton, West, North-west, Lichfield, Kingswinford, and Handsworth. The thirteen municipal boroughs, with their populations in 1891, are Burslem, 30,862; Burton on Trent, 46,047; Hanley, 54,846; Lichfield, 7864; Longton, 34,327; Newcastle-under-Lyme, 18,452; Stafford, 20,270; Stoke-upon-Trent, 24,027; Tamworth, 6614; Walsall, 71,791; Wednesbury, 25,342; West Bromwich, 59,489; and Wolverhampton, 82,620. Pop. of entire county (1801) 242,693; (1841) 509,472; (1881) 981,009; (1891) 1,083,273. Staffordshire has no great wealth of antiquities, and has been the scene of no battles more important than Blore Heath (1459) and Hopton Heath (1643). Among its natives have been Lord Anson, Ashmole, Dr Johnson, Thomas Newton, Cardinal Pole, Earl St Vincent, Izaak Walton, and Josiah Wedgwood.

See county histories by R. Plot (1686), S. Erdeswick (1717; 4th ed. 1844), S. Shaw (1798-1801), and R. Garner (1844-60); the *Proceedings* of the William Salt Archæological Society (1880 *et seq.*); and other works cited in Rupert Simms's *Staffordshire Bibliography* (Lichfield, 1892).

Stag is the term for the male of the Red Deer (q.v.). In Scotland the pursuit of the stag is mainly by deer-stalking, a long and laborious approach on foot allowing at best a chance of a rifle shot at the deer from a place of concealment. In England wild red deer are still hunted on horseback on Exmoor. The hounds are like foxhounds (see BUCKHOUNDS), and a good run may extend to 20 or 30 miles. The hunting season is 12th August—8th October, and 25th March—10th May. Elsewhere deer-hunting is the hunting of carted deer (usually fallow-deer) let loose from a van, the hounds being set on a quarter of an hour later. See DEER FORESTS, EXMOOR FOREST (and works there cited); *Hunting*, in the 'Badminton Library' (1885); and Fortescue's *Records of Stag-hunting on Exmoor* (1887).

Stag-beetle (*Lucanus*), a genus of Lamellicorn beetles, nearly allied to the Scarabees. The males are remarkable for the large size of their mandibles, the branching of which in *L. cervus* and *L. elaphus* has suggested stags' antlers. The common European Stag-beetle (*L. cervus*) is a large formidable-looking insect, the males being fully 2 inches long, and able to give a sharp bite with their strong mandibles. It flies about in the evening in the middle of summer, chiefly frequenting oak-woods. The larva feeds on the wood of the oak and willow, and is injurious to the trunks of trees, into which it eats its way very rapidly. It is supposed by some to be the *Cossus* of the ancient Romans, much esteemed by them as a delicacy. It lives for several years before undergoing its transformations (see BEETLE). In most species of Lucanus, and of the nearly related genus Passalus, are some shade of brown, but the tropical forms are often brilliant.

Stag-beetle (*Lucanus cervus*).

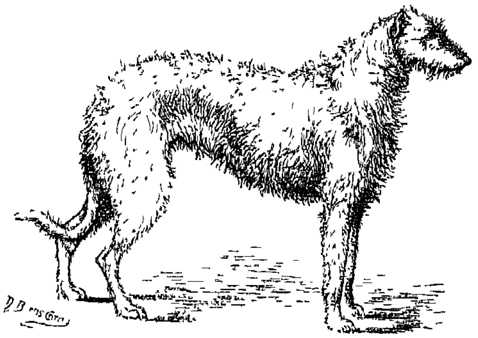
Stage-coach. See COACHING.

Staggers is a popular term applied to several diseases of horses. Mad or Sleepy Staggers is inflammation of the brain, a rare but fatal complaint, marked by high fever, a staggering gait, violent convulsive struggling, usually terminating in stupor; it is treated by bleeding, full doses of physic, and cold applied to the head. Grass or Stomach Staggers is acute indigestion, usually occasioned by overloading the stomach and bowels with tough hard grass, vetches, or clover, a full meal of wheat, or other indigestible food. It is most common in summer and autumn, is indicated by impaired appetite, distended abdomen, dull aspect, unsteady gait, and is remedied by full doses of purgative medicine, such as six drachms of aloes and a drachm of calomel rubbed down together, and given in a quart of thin well-boiled gruel. Frequent clysters, with hand-rubbing and hot water to the belly, are likewise useful. Where the dullness increases, non-alcoholic stimulants should be given. See also HYDATID.

Staghound, a name applied both to the Buckhound (q.v.) and to the Scottish deerhound. The latter breed has been established in Scotland from time immemorial, and has probably sprung from the same source as the Irish wolfhound and the smooth greyhound. A contest between two deerhounds is vividly described in Ossian's poems. The breed seems to have been in danger of extinction about the beginning of the 19th century, when crosses of fresh blood were tried, and the breed successfully revived. Owing to the altered conditions of sport the staghound can only be



Deerhound, 'Rossie Ralph.'

looked on now as an ornamental dog, as he is rarely used for pulling down the wounded deer, the purpose for which he was originally kept. The deerhound is an immense shaggy dog, standing nearly 30 inches high in some cases, and has a peculiar swing in his action suggestive of great speed, with a keen, determined expression. In conformation the deerhound is similar to the greyhound, but with more bone and power; the head is long, with powerful jaws. The body is covered with wiry hair about 3 inches long. The colour varies from dark gray to white. As an ornamental and graceful dog the deerhound is without an equal, and as a rule combines good temper with his other companionable qualities.

Stagi'ra. See ARISTOTLE.

Stahl, FRIEDRICH JULIUS, writer on law and jurisprudence, was born of Jewish parents at Munich on 16th January 1802. He became a Protestant when seventeen, studied law at the universities of central Germany, and in 1830 published the first volume of his greatest book, *Die Philosophie des Rechts*, the second volume of which appeared seven years later. In this work (of which the 3d improved edition in 1854-56 is the best) Stahl proclaimed the doctrine that belief in the revealed truths of the Christian religion is the only satisfactory basis of jurisprudence and politics. From 1832 to 1840 he taught alternately at Erlangen and Würzburg, and in 1840 was called to the chair of Philosophy of Law at Berlin. In the Prussian capital he acquired an influential position as a leader of the 'Junker' or reactionary party in the Chamber of Magnates (of which he was appointed a life-member) and as an uncompromising opponent of all political change, and the mouthpiece of a stern Lutheranism in the church assemblies He died at Brückenau (north-west corner of Bavaria) on 10th August 1861, a determined opponent to the last of the various liberal parties in both civil and ecclesiastical politics. He wrote several other books, as *Der Christliche Staat* (1847), in which he advocated a sovereign despotism grounded on a doctrine very similar to the 'divine right of kings;' *Der Protestantismus als politisches Princip* (1853); *Was ist Revolution?* (1852); *Wider Bunsen* (1856); and *Siebenzehn parlamentarische Reden* (1862).

Stahl, GEORG ERNST, author of the Phlogiston (q.v.) theory in chemistry and of the theory of animism in medicine (see Vol. VII. p. 118), was born at Ansbach on 21st October 1660, and held successively the appointments of court-physician (from 1687) to the Duke of Saxe-Weimar, professor of Medicine (from 1694) in Halle, and body-physician (from 1714) to the king of Prussia. He died at Berlin on 14th May 1734. His chemical theory was expounded in *Experimenta et Observationes Chemicæ* (Berl. 1731), and his medical in *Theoria Medica Vera* (Halle, 1707).

Stained Glass. See GLASS (PAINTED).

Stainer, JAKOB, violin-maker, was born at Absam near Hall in the Tyrol on 14th July 1621, and was apprenticed to a maker of stringed musical instruments at Innsbruck. There is a legend, devoid of foundation, however, that he worked under some of the Amati at Cremona. He did somehow learn the secret of the Italian method of constructing violins, and so won a reputation that passed beyond Germany, into Italy and England, and lasted for more than a century. At the present day his violins are valued as curiosities, but are not esteemed of use by practical musicians. Stainer died in 1683, insane, and, in spite of grand-ducal favour, in a state of poverty. There is a Life by Ruf (Innsbruck, 1872).

Stainer, SIR JOHN, organist and composer, was born in London, 4th June 1840, and became a chorister in St Paul's Cathedral. He was made organist of Magdalen College at Oxford in 1859, and there he successively took the degrees of Mus.Bac., B.A., Mus.Doc., and M.A. In 1872 he became organist of St Paul's Cathedral. He holds numerous other appointments, such as inspector of music to the Education Department, and professor of Music at Oxford (1889). In 1888 he was knighted. Among his works are the cantatas *The Daughter of Jairus* (1878) and *St Mary Magdalen* (1883), a *Treatise on Harmony* (5th ed. 1881), a *Dictionary of Musical Terms* (conjointly with W. A. Barrett, 3d ed. 1888), and several smaller primers and books on music.

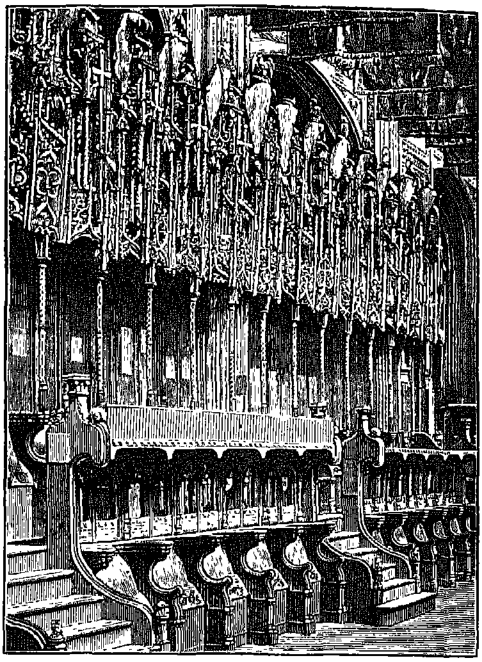
Staines, a picturesque town of Middlesex, on the left bank of the Thames, 6 miles SE. of Windsor and 19 WSW. of London (35½ by river). It took its name from the 'London Stone' (1280), marking the county boundary; it has a granite bridge by Rennie (1832); and in the neighbourhood are Runnimede, Egham, and Cooper's Hill, all noticed separately. Pop. (1851) 2430; (1891) 5060.

Stair, a village in Ayrshire which gives the title of Earl to the ancient Scottish family of Dalrymple. A Dalrymple of Stair was among the Lollards of Kyle summoned before James IV; his great-grandson was one of the earliest to make public profession of the Reformed doctrines.—James Dalrymple of Stair (1619-95) studied at Glasgow University, served in the army, and acted six years as Regent in Philosophy at Glasgow, next joined the bar (1648), and scarcely ten years after was recommended by Monk to Cromwell for the office of a lord of session, as 'a very honest man and a good lawyer.' He was confirmed in office, and created a Nova Scotia baronet in 1664. It was the death of his daughter Janet in 1669, within a month of her marriage to Dunbar of Baldoon, that gave Scott the tragic plot of *The Bride of Lammermoor*. His wife, who survived till 1692, was credited in Galloway with being a witch. About the close of 1670 Dalrymple was made president of the Court of Session and member of the Privy-council, and during the next ten years, if he distinguished himself by reforms in legal process, he must have winked hard at much wickedness and illegality in high places. The Duke of York took up the work of government at Edinburgh in 1679, and Dalrymple, who honestly hated Popery at least, soon found himself obliged to retire to the country. In his leisure he prepared his famous work, the *Institutes of the Law of Scotland*. His wife and his tenants were devoted to the Covenant, and accordingly he soon became involved in a fierce dispute with Claverhouse, who was ravaging Galloway with a military commission. In October 1682 he found it necessary to flee to Holland, returned with the Prince of Orange, and soon after was restored to the presidency in Lockhart's room. He was created Viscount of Stair, Lord Glenluce and Stranraer in 1690, was much molested by factious attacks during his last years, and died at Edinburgh, 25th November 1695. See J. G. Mackay's *Memoir* (Edin. 1873), and *The Stair Annals*, edited by J. Murray Graham (Edin. 1875).—His second son was Sir James Dalrymple (q.v.). Collaterally connected was the learned Lord Hailes (q.v.), whose own younger brother was the hydrographer Alexander Dalrymple (q.v.).

The eldest son, Sir John Dalrymple, first Earl of Stair, was born in 1648, and followed the hereditary profession of his family. He came into violent collision with Claverhouse in Galloway, and was flung into prison in Edinburgh and heavily fined, but early in 1687, by a remarkable turn in the royal policy, 'the springs' of which Wodrow prudently leaves 'to the civil historian of the period,' he had all his charges remitted, and became king's advocate, Lord Justice-clerk the next year. He acquiesced easily in the accession of William, became Lord Advocate, and for some years as Secretary of State had the chief management of Scottish affairs. On his shoulders, therefore, with Breadalbane and the king, mainly rests the infamy of the massacre of Glencoe (q.v.). He was created Earl of Stair in April 1703. He took an active part in the debates and intrigues that preceded the carrying of the Treaty of Union, and indeed fell a victim to his zeal in its cause, dying suddenly the morning after a long and vehement debate, 8th January 1707. 'He was,' says Defoe, 'justly reputed the greatest man of counsel in the kingdom of Scotland.' See Omond's *Lord Advocates of Scotland* (vol. i.), and J. Murray Graham's *Stair Annals* (2 vols. 1875).—John Dalrymple, second Earl of Stair, was the second son of the second viscount and first earl, and was born at Edinburgh, 20th July 1673. At eight he shot his elder brother dead by accident at the family seat of Carscreugh Castle in Wigtownshire. He was brought up in Holland, studied at Leyden, and early attracted the notice of the Prince of Orange. He volunteered for service, was present at Steenkerk, and by 1701 was lieutenant-colonel in the Scots foot-guards, in 1706 colonel of the Cameronians. He was aide-de-camp to Marlborough in 1703, and showed conspicuous courage at Venlo. He commanded a brigade of infantry at Ramillies, and was rewarded with the colonelcy of the Scots Greys in August 1706. He distinguished himself greatly at Oudenarde (1708), was promoted major-general, and commanded his brigade at the siege of Lille and at Malplaquet. His rank of general he received in 1712, after which he retired to Edinburgh to intrigue for the Hanoverian succession. In 1714 he married the beautiful and strong-willed widow, Eleanor, Viscountess Primrose, forcing her consent for the sake of her reputation by the artifice of concealing himself in her house and showing himself at her bedroom window. This audacious ruse afforded a foundation for Scott's story, *My Aunt Margaret's Mirror*. On the accession of George I. Stair returned to favour, and soon after was appointed ambassador to Paris. He played a great rôle under the regent Orleans, lived with splendid magnificence, yet checkmated at every turn the Pretender and the vast schemes of Alberoni. Recalled in 1720 with fortunes sadly impaired, he mainly devoted himself thereafter to agricultural improvements, introducing turnips and cabbages, while his clever wife became a leader of society in Scotland, and helped to make Moffat the fashion. On Walpole's fall Stair was made field-marshal (1742), and appointed governor of Minorca, without residence. He took the command of the army which was to act in support of Maria Theresa in conjunction with a Dutch and Austrian force, but had already lost ground strategically in presence of Noailles, when George II. came to take command in person. Stair showed his usual courage at Dettingen, but after the victory was allowed to resign. He died at Queensberry House, Edinburgh, 9th May 1747. See the *Annals* by Graham.

Stalactites, STALAGMITES. See CAVE, p. 34.

Stall, the technical English name for the seats in churches reserved for the clergy and choir, and usually lining the choir or chancel on both sides, sometimes in two or more rows. In cathedrals and other large churches they are generally enclosed at the back with a high screen, and are often surmounted with pinnacled canopies of tabernacle work, the backs and arms being usually carved in a more or less ornate manner. At the west end are often 'return' stalls, facing east, for the dean, warden, chancellor, or other dignitaries. In Henry VII.'s Chapel (1502-20), Westminster Abbey, the dark oak choir stalls, with their finely-carved Misereres (q.v.), are appropriated to the Knights of the Bath, and the lower seats to their squires; and each stall bears its occupant's armorial bearings in brass, with a sword and banner above. At Winchester, Chester, Windsor, and King's College, Cambridge, are also fine examples of stalls. Stall is often used as a synonym of prebend or canonry.



Stalls, Westminster Abbey.

Stallbaum, GOTTFRIED (1793-1861), rector of a school at Leipzig, and professor in the university, edited Herodotus and other authors, but is best known for his edition of Plato (12 vols. 1821-25).

Stalybridge, a cotton town of Cheshire and Lancashire, occupying a hilly site on both banks of the Tame, 7½ miles E. by N. of Manchester. Dating only from 1776, it has huge factories for the spinning of cotton yarns and calico-weaving, iron-foundries, and machine-shops, a town-hall (1831), market-buildings (1867), a mechanics' institute (1861), an Oddfellows' hall (1878), and, between it and Ashton-under-Lyne to the west, the Stamford Park (1873). It was made a municipal borough in 1857, a parliamentary borough in 1867. Pop. of the former (1851) 20,760; (1891) 26,783; of the latter (1891) 44,135.

Stamboul. See CONSTANTINOPLE.

Stamens are, with the Carpels (q.v.), the essential parts of Flowers (q.v.). The stamens taken together form the *andrœcium* or male part of the flower. Each stamen consists, usually, of two parts, a thin stalk or filament and an anther which contains the pollen (see FLOWER). The filament is not essential. The stamens of the mistletoe have none, and are *sessile*. The position of the stamens on the flower axis is always inside the flower-leaves, petals and sepals, and outside the fruit leaves, the carpels. But their position on the axis, whether below the carpels, as is most commonly the case, or on a level with them, or above them, varies, and is used as a means of classification. When they are inserted on the thalamus (flower receptacle) below the carpels the flower is said to be *hypogynous;* when, carried upwards by the continued growth of the outer part of the flower receptacle, they are inserted on the same level as the carpels then the flower is *perigynous;* when, carried up still farther, they are inserted above the carpels the flower is *epigynous.* If the stamens are adherent to the petals they are *epipetalous,* if adherent to the pistil (united carpels) they are *gynandrous.* If the filaments only are more or less coherent (Mallow) the stamens are *monadelphous;* if united into two bundles (pea) they are *diadelphous;* if only the anthers cohere then the stamen is *synantherous.* The stamens vary in number from a single one in a flower to as many as several hundreds. These variations also are used in classification. When the stamens are *definite,* few (five to ten) in number, the individuals are inserted one opposite each of the petals, or each of the sepals, or one opposite all of them. If they are less in number than the petals or sepals of the flower, then their position varies. When there is more than one whorl of stamens then the individuals of each whorl alternate with the individuals of the next whorl below it. Often the full number of stamens, that comparison with other flowers of the same order would lead us to expect, is not present; but usually aborted traces of them may be seen. Thus the Scrophularineæ are peculiar in having only four stamens, but the fifth is represented by a minute scale. Remnants of this description are called *staminodes.*

The stamens are commonly said to be metamorphosed leaves. But, since a leaf is defined as an appendage of the axis or stem, this statement is only an assertion of the general homology, or similarity of origin, of the two kinds of appendages. Often, too, stamens are said to be altered flower-leaves—i.e. petals. But this is a case of putting the cart before the horse. Stamens very commonly become petaloid, as for instance when a flower becomes 'double' under cultivation, and in a few cases in the natural state, the white water-lily for instance. In all such cases there may be seen in the same blossom a complete series of transition forms between stamens and petals. This indicates the homology of the two kinds of appendages, but of itself gives no evidence as to which form is the precursor of the other. But the fact that the Gymnosperms (q.v.), conifers, for example, which are older forms and are less highly developed than the true flowering plants, have stamens but not petals, shows that the petals of the Phanerogams are derived from stamens, and not the stamens from the petals. The further facts that the characteristic colour of stamens is yellow, and that the simplest, lowest flowering plants have yellow flowers, is another piece of evidence that leads to the same conclusion.

The anther which contains the fertilising pollen is the essential part of a stamen. The pollen is set free by the splitting—*dehiscence*—of the anthers. The mode of dehiscence is sometimes characteristic of the plant. Thus the anthers of the Rhododendra open and shed their pollen through a small circular pore at the upper end of each lobe; and in a few cases the dehiscence is transverse, or across the anther. But the most usual mode of dehiscence is by a longitudinal slit in each lobe, either on the inner or outer face of the anther.

The time at which the stamens dehisce relatively to the ripening of the stigma is important. For if the anther dehisces when the stigma is ready to receive pollen then the flower may be self-fertilised; but if it does not open at that time then self-fertilisation will be impossible, or nearly so, and that flower must be cross-fertilised. Stamens present numerous modifications of form that are apparently adaptations to the process of fertilisation.

See Sir John Lubbock's *Flowers in their Relation to Insects* ('Nature' series, 1875); Kerner's *Pflanzenleben* (vol. ii. 1891).

Stamford, a municipal borough chiefly in Lincolnshire, but partly also in Northamptonshire, on the Welland, 12 miles WNW. of Peterborough. Hengist is said to have here defeated the Picts and Scots in 449, and Stamford thereafter is notable as one of the Danish 'five burghs,' as having been visited by at least thirteen sovereigns (from Edward the Elder in 922 to Queen Victoria in 1844), for the persecution of its Jews (1190), as having between 1266 and 1334 only missed becoming a rival to Oxford, for its colony of Flemish Protestants (1572), as the birthplace of the earliest provincial newspaper, the *Stamford Mercury* (1695), and for its famous bull-running on 13th November from King John's time until 1839. It has lost ten of its sixteen churches, an Eleanor Cross, two castles, six religious houses, and two hospitals. Existing edifices are St Mary's, with a fine spire, All Saints, with a fine tower and steeple, St Martin's with Lord Burghley's grave and, in the churchyard, Daniel Lambert's, a town-hall (1777), corn exchange (1859), literary institute (1842), bridge (1849), Browne's Hospital (15th century), and boys' and girls' high schools (1874–76). 'Burghley House, by Stamford town,' is a magnificent Renaissance pile, dating from 1575, with a noble park, carvings by Grinling Gibbons, and a great collection of pictures. The trade and industries are mainly agricultural. Chartered by Edgar in 972, and afterwards by Edward IV., Stamford was a parliamentary borough, but lost one of its two members in 1867 and the other in 1885. For good services rendered by the inhabitants at the battle of Loose-coat-field (in 1469) the town seal bears the royal arms. Pop. (1851) 8933; (1891) 8358.

See works by Butcher (1646), Howgrave (1726), Peck (1727; new ed. 1785), Drakard (1822), Sharp (1847), Walcott (1867), and Nevinson (1879).

Stamford, a town of Connecticut, on Long Island Sound, 33 miles by rail NE. of New York. It has a handsome town-hall, and the hills around are embellished with the summer residences of well-to-do New Yorkers. Steamboats run daily to New York. There are iron and bronze foundries, and manufactories of hats, drugs, sashes and blinds, and Yale locks (see LOCK, p. 680). Stamford was settled in 1641. Pop. (1880) 11,297; (1890) 15,700.

Stamford Bridge, a small town in the East Riding of Yorkshire, on the river Derwent, 9¼ miles NE. of York by rail. It was the scene of the great victory of King Harold (q.v.) over the invading Norwegians under Harold Haarfager.

Stammering, or STUTTERING, is an infirmity of speech, the result of failure in co-ordinate action of certain muscles and their appropriate nerves. It is analogous to some kinds of lameness; to cramp or spasm, or partial paralysis of the arms, wrists, hands, and fingers, occasionally suffered by violinists, pianists, and swordsmen; to the scrivener's palsy, or writer's cramp, of men who write much. For speech—like writing, fencing, fingering a musical instrument, and walking—is a muscular act involving the co-ordinate action of many nerves and muscles.

The words stammering and stuttering practically denote the same infirmity. Any distinction that may have come to be established in the usage of them respectively would seem to be that stuttering —an onomatopœic word—is now limited more or less to the futile repetition of sounds, while stammering (akin to 'stamp,' 'stump,' 'step.' 'stop') covers the whole defect, the hesitation, glide, stop, holding on to the sound as well as repeating it. With defective articulation due to malformation—cleft palate, high-roofed mouth, disproportionate tongue and tonsils; or due to affectation and bad habit—interjection of meaningless sounds, lisping, burring, and other such imperfections of speech, we have nothing further to do in this article, beyond remarking that a fault of habit may be entirely cured, a faulty formation can only be mended, its irksomeness alleviated.

Since speech at a high degree of excellence is a fruit of advanced civilisation, it is not startling to be told that stammering does not prevail among Negroes in Africa and North American Indians. But when it is proved to be pretty wide-spread in Prussia, Great Britain and its colonies, and the United States of America, and uncommon in Italy and Spain, the question suggests itself whether languages of Teutonic origin are not more apt to generate stammering than languages of Latin origin. A much larger proportion of males stammer than of females.

Stammering, the chief of the imperfections of speech, may be hereditary, and it may be acquired by imitation. Like yawning, it is infectious. It may be the abiding result of mental strain or shock. Fever may bring it on, epilepsy, hysteria, any nervous affection, temporary failure of health, any excitement, soreness of the mouth. It rarely shows itself earlier than at four or five years of age. It usually begins in youth, but may be produced at any later age. It used to be ascribed exclusively to the organ of articulation, the mouth; to faulty setting of the teeth or the jaws, to the largeness and thickness of the tongue, its weakness of movement, its excessive vigour. The cause indicates the cure. A wedge was cut out of the tongue, lengthways, to make a path for the current of air. The root of the tongue was cut to break its excessive vigour. The tongue was thought to lie too flat on the bottom of the mouth; a plug was inserted to raise it, Demosthenes and the pebbles being referred to. It was one of the secret cures to tell the stammerer to keep the tip of his tongue on the roof of his mouth. An improvement on this was to keep the whole breadth of the tongue lying on the palate. When, by-and-by, the breathing began to be taken into account, stammering was explained exclusively by reference to the organ of respiration, and the cure was breathing exercises which were kept secret. The latest step in the research for the cause and cure of stammering has been to take full account of the vocal chords or cushions and the vocal chink.

Stammering occurs in the mouth, the organ of articulation. Its proximate cause is always in the larynx, the organ of voice. Sometimes the lungs, the organ of breathing, complicate the uncertainty and unsteadiness of the vocal chords and the vocal chink in the larynx. A current of air, variously shaped by the mouth as a whole, is what we call a vowel. A stammer on a vowel can only take place in the vocal chink, *rima glottidis.* The sounds called consonants are produced by closures, more or less firm, of contents of the mouth. Thus, *b, p, m, w,* by the closure of the two lips; *f, v,* of the lower lip and upper teeth; *g* soft and *sh,* of the teeth; *l* and *th,* tongue and upper teeth; *t, d, n, s, z, y,* tip of the tongue and fore gum; *g* hard and *k,* back edges of the tongue and back gum. Stammering may occur at any of these six closures. It is, perhaps, most apt to occur at the labials *b, p,* the dentals *d, t,* the gutturals *g* hard, *k,* because for these the closure is firmest. The stammerer has no difficulty in setting lips, teeth, tongue, and gums against each other as required. His difficulty is to relieve the closure, to get at the vowel which is to follow the consonant. The tongue, for example, will not part with the teeth, seems to cling spasmodically to them. Why? Because the current of air, the vowel, does not come at the proper instant through the vocal chink to relieve it. In this way the three observable modes of stammering are explained. If the vocal chink does not open soon enough there is a stop stammer; if it flutters, there is a stutter; if it opens too soon, there is a glide stammer. But, further, the lungs expand and contract by nervous and muscular energy; and, besides, the muscular and nervous machinery of the breastbone, ribs, midriff, and upper abdomen are all concerned in that expansion and contraction. These complicated and delicate bellows which supply air under pressure to the organ of voice may be defective, out of order, misused. Their working is to be closely observed in the case of each stammerer. Stammerers, as a rule, breathe badly. They constantly try to speak when their lungs are empty.

Stammering can be cured. It often disappears gradually without effort at cure. Improvement generally takes place as age advances. In some cases resolute endeavour is demanded. A waving motion of the arms, time kept to a baton, were favoured as cures at one time. They were on the lines of the musical methods of cure—intoning, chanting, singing—which were based on the fact that most stammerers can sing. The doctrine of this article suggests as instructions for cure: Regulate the breath. Work for an habitual use of the chest voice—i.e. for deeper, steadier vibration of the vocal chords—because people generally stammer in a head voice. Take exercise, in a chest voice, on the sounds (seldom vowels) at which a stumble is apt to be made.

Stamp Act, a measure which required all legal documents in the colonies to bear stamps, proposed by Grenville, then premier, and passed by parliament in 1765. The Americans denied the right to the English parliament, in which they were not represented, to impose taxes upon them, and offered violent opposition. Riots took place in many of the towns, the offices were seized, and the stamped paper destroyed; while a congress of delegates of nine of the states met at New York in October, and passed resolutions claiming for the provincial assemblies the exclusive right of taxation. In the January of 1766 the subject was brought before parliament. In the great debate that followed Burke made his maiden speech, and Pitt, who had been absent for a year, in one of his greatest speeches denied the absolute right of parliament to tax the colonies, as taxation and representation went hand in hand. After examining witnesses, chief among them Franklin, the ministry proposed the repeal of the Stamp Act, and carried it on February 21. Thus Pitt's wisdom staved off for a time the breach between England and her colonies.

Stamps, impressed and adhesive, are extensively used for making and verifying payments of money. Stamp-duties were first imposed in England in 1694; the basis of the existing law is the Stamp Act of 1870; see Griffith's *Digest of the Stamp Duties* (9th ed. 1888). For the protection of the public revenue penalties are imposed; thus any person receiving a premium of insurance without issuing a properly stamped policy is liable to a fine. Where the law requires a stamp, an unstamped document cannot be given in evidence in civil proceedings unless the party producing it is willing to pay the duty and an additional penalty. Stamp-duties are a form of indirect taxation. It is admitted that they ought to be moderate in amount; excessive duties on negotiable instruments, transfers of property, or legal proceedings would operate to the discouragement of business. The amount of the stamp-duties received in the United Kingdom has risen from £6,726,817 in 1840 to £8,040,091 in 1859-60, £11,306,914 in 1879-80, and £13,460,000 in 1890-91. See Tilsley, *Stamp Laws*. During the American civil war (1861-65) stamp-taxes were laid on all manner of legal documents, bank drafts, cheques, and on the packages of various kinds of manufactured goods, but these were gradually withdrawn. The last stamp-taxes on matches, proprietary articles, playing cards, bank cheques and drafts were repealed in 1883; and the revenue from adhesive stamps, which was $4,140,175 in 1863, rose to $16,544,043 in 1870, and was $7,053,053 in the last year, vanished from the internal revenue returns. Forgery (q.v.) of stamps is severely punished.

Stamps for postal purposes were used, or it was proposed they should be used, in Paris as far back as 1653. Stamped paper on covers for that purpose, both with impressed and embossed stamps, seem to have been used in the kingdom of Sardinia in 1819, several values being provided for. Charles Knight suggested the idea of using stamps for the prepayment of postage in 1833-34. Stamps or labels, to be gummed or pasted on articles liable to duty, were in use by the British Inland Revenue department in the days of George III., though they were not issued ready gummed. The use of a piece of stamped paper just large enough to bear the stamp, with a glutinous wash on the back rendered adhesive by moisture, was recommended by Sir Rowland Hill (q.v.) in a pamphlet of 1837; and his post-office reform of 1840 gave opportunity for carrying out the suggestion with success.

Not till 1879 was it disputed that the credit of the adhesive postage-stamp was due to Sir Rowland Hill; though in 1846 Mr James Chalmers, a bookseller of Dundee, received a testimonial from his fellow-citizens for the post-office reforms advocated by him, including the use of adhesive stamps; but from 1879 onwards till 1891 a pamphlet controversy was carried on by Mr Patrick Chalmers, insisting that the credit was wholly due to his father. The idea, it was affirmed, was fully developed as early as 1834. Specimen stamps were made and exhibited in that or the next year on Mr Chalmers' premises, the plan was submitted to Sir Rowland Hill in 1839, and was then, but not before, taken up by the latter. This was strenuously denied by Mr Pearson Hill (Sir Rowland's son). Mr Hill read an elaborate statement on the subject before the London Philatelic Society in November 1881, affirming that Mr Chalmers had failed to produce any evidence that his father had suggested adhesive stamps in 1834, or had communicated his ideas on the subject to anybody before 1839—a date years subsequent to that at which Sir Rowland Hill had already recommended this valuable practical device. The Philatelic Society, after opportunity had been given to Mr Chalmers for proving his case, decided that he had failed to produce the evidence to prove that Sir Rowland Hill had derived the idea from Mr Chalmers. Both may have hit on the plan independently: but adhesive stamps without the uniform penny rate would have been complicated and cumbrous; Sir Rowland's reform of 1840 for the first time made the adhesive stamp, which he had suggested at the beginning of 1837, a practical suggestion. Mr Pearson Hill's case maintaining his father's claim was published in 1888 as a pamphlet, entitled *The Origin of Postage Stamps*. Mr Chalmers on his side also issued numerous pamphlets with many testimonies from persons professing to remember the suggestion of adhesive stamps by Mr James Chalmers in 1834 and subsequent years, but without any contemporary documents to certify the early date maintained.

With the postal reform of 1840 the Franking (q.v.) of letters was abolished in Britain, and penny stamps introduced. The first English postage-stamp was black; but the same year Mr Mulready designed the famous 'Mulready envelope,' intended to be both cover and stamp, which was not a practical success and was withdrawn the same year. Since then upwards of 100 stamps of various values have been used in Britain: in the British empire, including colonies and dependencies, upwards of 1600 different postage-stamps are or have been in use. The red penny stamp in use in Great Britain from 1864 to 1880 underwent some hundred and fifty minor modifications, so that for stamp-collectors Britain itself presents a large field. The use of adhesive stamps was authorised in the United States in 1847; prepayment of stamps was made compulsory in 1856.

Stamp-collecting began to be a common and fashionable hobby about 1861, which spread from Britain to the Continent: and in 1890 there were three collections of postage-stamps of all kinds of which the aggregate value was estimated at more than £100,000. The stamp-collecting pursuit, which claims to be a science, is called philately, timbrophily, and timbrology; and there are numerous philatelic societies in Britain and abroad which publish transactions or journals. Rare stamps bring high prices. The Mulready penny envelope is worth from 8s. to £1; a stamp of the first Sandwich Islands issue of 1852 may be worth £65. An English 1847 stamp with postal mark will fetch £75. Two of Mauritius of 1847 have together been sold for £200.

See works on postage-stamps of all kinds or stamp-collecting by Captain Evans (1885), Ogilvy (1883), Palmer (1888), and others; for British postage and telegraph stamps, see Philbrick and Westoby (1881).

Standard. See FLAG, CURRENCY, MONEY, BIMETALLISM, WEIGHTS AND MEASURES; and for the Battle of the Standard, NORTHALLERTON.

Standing Orders is the name given to permanent regulations made by either House of Parliament for the conduct of its proceedings, and enduring from parliament to parliament unless rescinded. A standing order of the House of Lords when rescinded is said to be *vacated;* in the Commons the corresponding term is *repealed.* In the Lords a motion for making or dispensing with a standing order cannot be granted on the same day that the motion is made, or till the House has been summoned to consider it; and every standing order as soon as agreed to is added to the 'Roll of Standing Orders,' which is carefully preserved and published from time to time. In the House of Commons there was until 1854 no authorised collection of standing orders, except such as related to private bills. In that year a manual of rules, orders, and forms of proceeding relative to public business was drawn up and printed by order of the House. Standing orders are occasionally suspended when it is desirable that a bill should be passed with unusual expedition. See May, *Parliamentary Practice*.

Standing Stones, or monoliths of unhewn stone, erected singly or in groups, are met with almost everywhere. They are not in all cases necessarily of ancient origin, but the motive of their erection may be presumed to have been in general honorary or commemorative either of events or individuals. In certain cases, however, they marked the boundaries of sanctuary or proprietary rights. Single stones, sometimes of great size, are often found standing in sites where no memory or tradition of their purpose exists. Occasionally accident or investigation discloses the fact that they mark the sites of prehistoric burials. They are sometimes arranged in groups of two or four, placed at short distances apart, as at Lundin Links, near Largo, in Fife, three of which are still standing (about 18 feet in height), as shown in the engraving. Such groups if composed of a large number of stones may be arranged in the form of circles, or avenues, or alignments, or groups of irregular lines converging slightly at one end. When arranged in the form of circles they are usually considered as belonging to a special class of prehistoric monuments or burial-places known as Stone Circles (q.v.). Other groups of standing stones arranged in lines like those of Carnac (q.v.) in Brittany, however, are as yet undetermined as to their purpose, though they are unhesitatingly assigned to the prehistoric period. Smaller groups than the famous ones of Brittany are found in the north of Scotland, and are sometimes associated with burial cairns, presumably of the age of bronze.

Standing Stones, Lundin Links, Fifeshire.

Several of these have been described in Caithness, the largest consisting of about 450 stones disposed in twenty-two rows of about 150 feet in length. In Norway groups of standing stones arranged in triangular and rectangular forms occur, and are known by investigation to be burial-places of the iron age. Commemorative monuments of the early Christian time frequently consist of unhewn blocks of stone having short inscriptions cut on their smoother faces, or incised with crosses or symbols. See Ferguson's *Rude Stone Monuments* (1872), and other works cited at ARCHÆOLOGY and SCULPTURED STONES.

Standish, MYLES, was born at Duxbury, Lancashire, about 1584, served in the Netherlands, and, though not a member of the Leyden congregation, sailed with the *Mayflower* colony to Massachusetts in 1620, and became the champion of the Pilgrims against the Indians. During the first winter his wife died, and the traditional account of his first effort to secure another partner has been made familiar by Longfellow. In 1622, warned of a plot to exterminate the English, he enticed three of the Indian leaders into a room at Weymouth, where his party, after a desperate fight, killed them, and a battle that followed ended in the flight of the natives. In 1632 he settled at Duxbury, Massachusetts, where he died, 3d October 1656. Standish was the military head of the colony, and for long its treasurer. A monument, 100 feet high and surmounted by a statue, has been erected to him on Captain's Hill, at Duxbury. See the Rev. B. F. De Costa's *Footprints of Miles Standish* (Charlestown, 1864).

Stanfield, CLARKSON, landscape-painter, was born of Irish Roman Catholic parents at Sunderland in 1794. He became a sailor, and in the China seas he served for a time in the same ship with Douglas Jerrold. He showed talent both in painting and drawing, and was taken note of by Captain Marryat. Stanfield left the navy in consequence of an injury to his feet, caused by a fall from the mast-head, and about 1818 took to scene-painting as a means of earning his bread—at first in the Old Royalty Theatre, and afterwards in Edinburgh and at Drury Lane. While painting for the theatres he had by no means neglected easel-painting. The first picture by him that attracted any considerable notice was 'Market-boats on the Scheldt,' exhibited at the British Institution in 1826. In 1830 Stanfield exhibited at the Academy his 'Mount St Michael, Cornwall,' which placed him at once in the foremost rank as a marine painter. In 1823 Stanfield, in conjunction with David Roberts and others, founded the Society of British Artists. Elected A.R.A. in 1832 and R.A. in 1835, he continued to send pictures to the Academy till his death at Hampstead, 18th May 1867. Among his best-known pictures, marked by truth, finish, and poetic feeling, were 'The Abandoned' and 'The Wreck of a Dutch East Indiaman.'

Stanford, CHARLES VILLIERS, musical composer, was born at Dublin on 30th September 1852. He entered at Queen's College, Cambridge, and in 1873 was appointed organist at Trinity College there. Except his operas, most of his works have been produced at one or other of the musical festivals in the provincial capitals of England — Gloucester, Birmingham, Leeds, Norwich, &c. His best and most successful productions have been the choral settings of Tennyson's *Revenge* (1886) and the *Voyage of Maeldune* (1889); the oratorios *The Three Holy Children* (1885) and *Eden* (1891); the operas *The Veiled Prophet of Khorassan* (1881), *Savonarola* (1884), and *The Canterbury Pilgrims* (1884); an orchestral serenade; a couple of symphonies, particularly the Elegiac symphony (1882); and some pieces for the violin and pianoforte. In 1882 he was appointed professor of Composition and Orchestral Playing in the Royal College of Music, and in 1887 succeeded Sir G. A. Macfarren as professor of Music in the university of Cambridge.

Stanford, LELAND, railway constructor, millionaire, and senator, was born at Watervliet, New York, 9th March 1824, and in 1856 settled in business in San Francisco. A strong supporter of the Pacific Railway scheme, he was made president of the Central Pacific Company, and superintended the construction of the line. Already governor of California, he was in 1885 elected a United States senator. Out of a fortune estimated at more than $50,000,000 he gave to the state of California $20,000,000 to found, in memory of his son, a university at Palo Alto (q.v.), where, over and above the usual academic studies, telegraphy, type-setting, farming, journalism, &c. should be taught.

Stanhope, a town in the county of Durham, on the Wear, 26 miles W. of Durham by rail Its rectory, once known in the north country as the 'golden rectory,' was held by Bishop Butler (1725–40). The famous lead-mines are now much less profitable than of old. Pop. 1840.

Stanhope, Lady Hester Lucy, the eldest daughter of Charles, third Earl Stanhope, and his wife Hester, daughter of the great Lord Chatham, was born at Chevening, Kent, on 12th March 1776. She grew up to be a woman of great personal charm and of unusual force and originality of character. In 1803 she went to reside with her uncle, William Pitt, and as mistress of his establishment and his most trusted confidant during his season of power and till his death she had full scope for the exercise of her imperious and queenly instincts. On Pitt's death in 1806 a pension of £1200 a year was assigned her by the king. Fox proposed to provide for her much more munificently, but she proudly declined his offers, as unwilling to accept benefit at the hands of the political enemy of her dead uncle. The change from the excitements of a public career, as it might almost be called, to the life of an ordinary woman of her rank with means somewhat insufficient was naturally irksome to her, and in 1808 she was tried still further by the death at Corunna of her favourite brother Major Stanhope, and of Sir John Moore, for whom she is known to have cherished an affection. Conceiving a disgust for society, she retired for a time into Wales, and in 1810 left England never to return. In mere restlessness of spirit she wandered on the eastern shores of the Mediterranean, and finally in 1814 settled herself among the half-savage tribes of Mount Lebanon. Here she led the strangest life, adopting in everything the Eastern manners, and by the force and fearlessness of her character obtaining a wonderful ascendency over the rude races around her. She was regarded by them with superstitious reverence as a sort of prophetess, and gradually came so to consider herself. With the garb of a Mohammedan chieftain, she adopted something of the faith of one, and her religion, which seems to have been sincere and profound, was compounded in about equal proportions out of the Koran and the Bible. Her recklessly profuse liberalities involved her in constant straits for money; and her health also giving way, her last years were passed in wretchedness of various kinds, under which, however, her untamable spirit supported her bravely to the end. She died on 23d June 1839, with no European near her, and was buried in her own garden. The main sources of information about her are the notes of Lamartine, Kinglake, and other travellers who visited her in her strange seclusion, and the *Memoirs and Travels* derived from her own lips, and afterwards (6 vols. Lond. 1845–46) published by Dr Meryon, the physician who went abroad with her, and from time to time lived with her in her retirement.

Stanhope, Philip Henry, Earl, historian and biographer, was sixth in descent from the first Earl of Chesterfield, and fourth from James, first Earl Stanhope (1673–1721), an eminent military commander, who effected the reduction of Port Mahon in Minorca, and was the favourite minister of George I. His grandson, Charles, third Earl (1753–1816), was an advanced Liberal, distinguished for his scientific researches, and the inventor of a printing-press which bears his name. The subject of this notice, only son of the fourth earl, was born at Walmer, 31st January 1805. He took his B.A. at Oxford in 1827, and seven years later was created D.C.L., having entered the House of Commons in 1830. He was greatly instrumental in 1842 in securing the passing of the Copyright Act (q.v.), was Under-secretary for Foreign Affairs during the brief Peel administration (1834–35), and Secretary to the Indian Board of Control under the same minister (1845–46). He was a moderate Conservative in politics, and was warmly attached to Sir Robert Peel, who named him one of his literary executors, and whose Memoirs he edited in conjunction with Mr Cardwell. His contributions to history are numerous and valuable. Macaulay, in a review of his *War of the Succession in Spain* (1832), credits him with some of the most valuable qualities of a historian—viz. perspicuousness, conciseness, 'great diligence in examining authorities, great judgment in weighing testimony, and great impartiality in estimating characters.' His most considerable work is *A History of England from the Peace of Utrecht to the Peace of Versailles, 1713–83* (7 vols. 1836–54); and his other works include Lives of Belisarius, Condé (originally in French), and Pitt; a *History of Spain under Charles II.*; an edition of *Lord Chesterfield's Letters*; *Historical and Critical Essays*; and *Miscellanies.* He was elected President of the Society of Antiquaries (1846), and Lord Rector of the university of Aberdeen (1858). He was known by the courtesy title of Viscount Mahon till 1855, when he succeeded his father in the earldom. He was mainly instrumental in procuring the appointment of the Historical Manuscripts Commission and the foundation of the National Portrait Gallery. In 1872 he was elected one of the six foreign members of the Academy of Moral and Political Sciences at Paris, and he died at Bournemouth, 22d December 1875.

Stanislaus. See Poland, pp. 271–2.

Stanislawow, or Stanislau, a town in the Austrian crown-land of Galicia, stands on the Bistritza, 87 miles by rail SE. of Lemberg, has important railway workshops, brick-works, &c., and is the seat of a Greek-Catholic archbishop. Pop. 18,626, of whom more than 10,000 are Jews.

Stanley. See Derby (Earl of).

Stanley, Arthur Penrhyn, born at the rectory, Alderley, 13th December 1815, the second son and third child of the Rev. Edward Stanley (1779–1849, second son of Sir John Thomas Stanley of Alderley, Bart.), for thirty-two years rector of Alderley, Cheshire, and for twelve bishop of Norwich. The bishop's elder brother was raised to the peerage, under the title of Baron Stanley of Alderley, in 1839. Arthur Stanley was educated at Rugby under Dr Arnold, and at Oxford, where he entered Balliol in 1834, and had Tait (afterwards Archbishop of Canterbury) for tutor. He took the Ireland scholarship and the Newdigate prize poem, and in 1837 a first-class degree. In 1839 he was elected a Fellow of University College and entered holy orders. In 1840 he travelled in the East, and from 1841 to 1851 lived at Oxford and did duty as tutor in his college; in 1845 was appointed select preacher; in 1851 canon of Canterbury; in 1856 professor of Ecclesiastical History, and canon of Christ Church, and in 1863 Dean of Westminster, in succession to Trench, promoted to the archbishopric of Dublin. In 1874 he was elected Lord Rector of the university of St Andrews. A voluminous writer in the periodical press, he was author of the *Life of Arnold* (1844), *Sermons and Essays on the Apostolic Age* (1847), *Memoir of Bishop Stanley* (1851), *Commentary on the Epistles to the Corinthians* (1855), *Memorials of Canterbury* (1855), *Sinai and Palestine* (1856), *Historical Memorials of Cambridge* (1857), *Lectures on the Eastern Church* (1861), *Sermons preached during a Tour in the East* (1863), *Lectures on the Jewish Church* (1863–65), *Memorials of Westminster*

Abbey (1866), *Essays on Church and State* (1870), *Lectures on the Scottish Church* (1872), *Addresses and Sermons delivered at St Andrews* (1877), *Sermons and Addresses* (1878), *Memorials of Edward and Catherine Stanley* (1879), and *Christian Institutions* (1881). The outstanding events in Stanley's personal history, after his public life had begun, were his travels in Egypt and Palestine in 1852–53, which suggested his *Sinai and Palestine*, and those in Russia in 1857, during which he collected the materials for the vivid pictures of the ecclesiastical life and history of Russia which occupy the last four lectures of his *Eastern Church*; his accompanying the Prince of Wales on his Eastern tour in 1862; his marriage in 1863 to Lady Augusta Bruce (1822–76), of the Elgin family; a second visit to Russia in 1874, when he celebrated the English marriage of the Duke and Duchess of Edinburgh; and his visit to America in 1878.

Stanley had a keen sense of humour; his talk was bright and abundant, passing easily from grave to gay, wholly free from affectation, gossip, or ill-natured or ill-informed chatter of any sort. Few men, if any, of his generation had a wider and more diversified circle of friends and acquaintances. His large tolerance, charity, and sympathy drew round him, by an irresistible attraction, all but the extreme bigots of ecclesiastical parties. To these he was the object of special aversion. High Church Anglicans in particular could never forgive him for championing Colenso, for preaching in Scottish Presbyterian pulpits, and for administering the holy sacrament in Henry VII.'s chapel to the revisers of the authorised version—one of them being a Unitarian, and several Presbyterians. This action, however, was in perfect accordance with the principle on which he governed the Abbey, recognising it as a great Valhalla, above all sectarian jealousies and divisions, to be used in the interests of religious concord and liberty. Among his last words were these: 'I am humbly trustful that I have sustained before the mind of the nation the extraordinary value of the Abbey, as a religious, national, and liberal institution.' It was his pride to add to its treasures, to enrich and multiply its services, and to throw it freely open to the people, multitudes of whom he, week after week, would conduct through it, explaining to them its history and contents. In his character as a churchman Stanley was pre-eminently representative of the highest culture and the broadest theology of the Church of England. He had inherited from his father the bishop, and had imbibed from Arnold his master, just and liberal ideas as to what a national church should be—comprehensive, intellectually free, charitable, and not aggressive in its relations to nonconformity. The Church of England, he maintained, 'by the very condition of its being, was not high or low, but broad.' Of this breadth he held the connection with the state to be the safeguard. The supremacy of the crown was simply the supremacy of the law, the removal of which would expose the just freedom of theological thought and of clerical action to the dominion of individuals or courts—none the less likely to be oppressive because they would claim to wield, by divine right, a purely spiritual power. In the current sense of the terms, Stanley was both Erastian and Latitudinarian; but only because of his love of liberty, which he felt endangered by the pretensions of sacerdotalism on the one hand and of orthodox dogmatism on the other. Christianity to him was sacred because of its moral and spiritual elements, and the divinely perfect life which embodied these; but for the systematic theology which had grown up around the evangelic records and the apostolic teaching he had little reverence; and he had none at all for the pretensions and 'mysteries' of the priesthood. The controversies about attitudes, lights, vestments, and the like, which agitated the Anglican Church, could not be lifted, in his opinion, out of the region of 'the infinitely little,' even by the doctrinal relations which exalted them in the eyes of the ritualistic party. The relish with which he traced details of ecclesiastical dress and usage back to their—often homely and simple—historical origins was as exasperating to the ritualist as the energy with which he threw himself into the defence of the theological position of Maurice, of the writers of *Essays and Reviews*, and of Bishop Colenso was to the ordinary evangelical. While the evangelicals deplored his lack of the 'root of the matter,' the ritualists sneered at him as 'the honorary member of all religions,' and 'the chief Nonconformist in the Church of England.' But Stanley held on his way, urged not only by his love of freedom, but by an innate chivalry of spirit which responded to the appeal of every vilified name, or struggling cause, or forlorn hope, but which was repelled by the self-assertion of the prosperous, the arrogance of the powerful, and the dull self-satisfaction of the conservative traditionalist. Thus, while he refused to let the Pan-Anglican Synod shelter its congress under the great name of the Abbey, he asked Colenso to preach there while under the ban of Convocation; and when Père Hyacinthe broke with the Roman hierarchy, and encountered the ecclesiastical and social ostracism which visited his marriage, he found refuge and countenance for himself and his wife beneath Stanley's roof.

Naturally Stanley's literary work does not entitle him to rank among doctors of dogmatic theology. His one purely theological book was that on the Epistles to the Corinthians; but in it he led the way to that application of fresh and open criticism and of vivid historical illustration to the sacred text in which he has been followed by all the best English exegetes of the present day. He was most at home in historical delineation and exposition. Probably in all his works exact dogmatists might mark here and there a vagueness of definition, and keen critics detect a hasty induction or a historical inaccuracy; but no one could fail to admire the faculty of living reproduction of the past, of picturesquely apposite illustration, of adaptation of every collateral aid and association in producing the one perfect impression he wished to stamp on the memory; or to sympathise with the lofty ideal of human life—the firm faith in the divine righteousness, the scorn of baseness, the love of truth, that brightened every page.

As a preacher from the pulpit of the Abbey Stanley wielded a wide influence. His congregation there was the great multitude that thronged the church whenever it was known he was to preach; and his sermons always conveyed a message of high religious purpose, of peace and reconciliation, and at any public crisis, or after any national loss, enforced, with perfect grace and wise moderation, the proper lesson, or paid the fitting tribute, or pointed the essential moral. Availing himself of the independent position which was his as successor to the Abbots of Westminster, and which laid him under no episcopal jurisdiction, he used to invite friends from the ranks of English nonconformity and of the Scottish Church, and even such an illustrious layman as Max-Müller, to address the congregation that filled the nave at evening service; thus, and by every means in his power, seeking to show his catholicity and his desire to break down walls of separation.

Stanley's position in society was unique. His ancient lineage, his independent and exalted ecclesiastical office, his personal popularity, his alliance with a lady of marked mental ability and social charm, who like himself was a *persona grata* at the Queen's court, all combined to invest the Deanery with a prestige and influence, as a centre of society, possessed, we may safely say, by no great contemporary house either of the English hierarchy or aristocracy. All that was really best in London society was to be met in Lady Augusta's *salon;* whatever was freshest and most genuine in literature, science, and art, most distinguished in character, most interesting in any department of life gravitated thither, and was received with warm and gracious welcome. With his wife's death a blight seemed to fall on the Deanery and its master; and during the few years that he survived her his life was obviously wounded too deeply to recover its elasticity, and too grievously stricken by the loss of 'the inseparable partner in every joy and struggle of twelve eventful years' to be able to withstand the attack of sharp disease such as seized him in the summer of 1881. He sank rapidly. Among his farewell words were: 'I always wished to die at Westminster;' and there he died, in the Deanery, before midnight on Monday, 18th July. He was buried by the Queen's commands beside his wife in Henry VII.'s chapel. He had left directions, which were duly obeyed, that among his pall-bearers there should be a minister of the Church of Scotland and an English Nonconformist, and that the Abbey on his funeral day should be freely open to the people. A beautiful recumbent effigy in white marble covers his tomb in the royal chapel.

The promised Life by Dean Bradley had not yet appeared in 1892; his *Recollections* were printed in 1883.

Stanley, Henry Morton, the African explorer, although a citizen of the United States, was born near Denbigh in Wales about 1840. His parents were in humble circumstances, and at an early age John Rowlands, as his name then was, had to shift for himself. When still a lad of fourteen or fifteen he left England, and the story goes that he worked his way as a cabin-boy to New Orleans, where he was fortunate enough to obtain employment in the office of a merchant named Stanley. He assumed the name of his employer, who took a keen interest in the young Welshman; but on the death of the merchant intestate he was again thrown on his own resources. He served in the Confederate army, and appears to have become a contributor to several American journals. In 1867 he was acting as correspondent for the *New York Tribune* and the *Missouri Democrat* on a military expedition against the Indians, and towards the close of that year began his connection with the *New York Herald.* It was as its special correspondent that Stanley first entered Africa. He accompanied Lord Napier's Abyssinian expedition, and so ably did he make his dispositions that the first news of the fall of Magdala was conveyed to the British public—and also to the British government—by the *New York Herald.* Stanley next went to Spain for his paper, and while in Madrid received the famous telegram from Mr Gordon Bennett summoning him to Paris; he went at once, and received the laconic instructions to 'find Livingstone.' This was in October 1869, but Stanley did not at once proceed on his new mission; he visited Egypt for the opening of the Suez Canal, and travelled through Palestine, Turkey, southern Russia, and Persia, arriving in India in August 1870. In the following January he reached Zanzibar, and towards the end of March he set out on his first expedition into the heart of the dark continent. Two white men who accompanied him soon turned back; there was the usual trouble with the porters; but in those early days Stanley displayed the qualities of courage, perseverance, and command over the native African which have won for him such a high position in the long roll of African explorers. The road to Tanganyika was not then what it is now; but all difficulties were overcome, and on November 10th Stanley had the satisfaction of greeting Livingstone. For four months they remained together, and there can be little doubt that the influence and example of Livingstone during these four months had a lasting effect on Stanley's character and career. Stanley met Livingstone a special correspondent; he parted from Livingstone with the fever of African exploration burning in his veins. The two men had together explored the north end of Lake Tanganyika, and conclusively settled that the lake had no connection with the Nile basin. On March 13, 1872, Stanley left Livingstone and set out on his return to the coast, having left large quantities of goods with the veteran, and given promises of further assistance. In less than two months he arrived at Zanzibar, and in August in England, where he was awarded the medal of the Royal Geographical Society, and fêted as the lion of the hour. His book, *How I Found Livingstone,* had an enormous sale. During the Ashanti campaign he followed the fortunes of Sir Garnet Wolseley's troops, for the *New York Herald,* and he returned to London only just in time to assist at the funeral of Livingstone in Westminster Abbey. The news of Livingstone's death kindled in Stanley a great resolution to complete the work in which his master had lost his life.

An expedition fitted out at the joint charge of the *New York Herald* and the *Daily Telegraph* was projected, with Stanley in supreme command. In August 1874 he left England to attempt the solution of some of the great problems of Central African geography. In November, with some 350 men of all descriptions, he quitted Bagamoyo, following the ordinary route to Ugogo, when, turning suddenly northwards, he made for the southern shore of the Victoria Nyanza. From Kagehyi, on Speke Gulf, he circumnavigated the lake, and approximately fixed its general outline. In Uganda he formed a close friendship with King Mtesa, and on his return home his reports of the readiness of the king to receive instruction in the Christian religion led to a great outburst of missionary enthusiasm, and the establishment of mission stations in Uganda. At Bambireh, an island off the south-west shore of the lake, he came into serious conflict with the natives, and the severe punishment he inflicted was subsequently made the subject of much hostile criticism in England. Passing through Karagwé, he reached Tanganyika, and set himself to determine its exact configuration. This accomplished, he made his way to Nyangwé on the Lualaba, where he first met Tippu Tib, the Arab chief; and from Tippu he learned that Cameron had not attempted the solution of the problem suggested by this great mass of water flowing northwards. It is of course impossible to give even in the barest outline the story of Stanley's ten months' journey from Nyangwé to the sea, by which he traced the course of the Congo and filled up an enormous blank in the map of Africa. When he arrived at Boma all his white companions were dead, hardly a third of his native followers had survived, and Stanley's black hair had turned white. It would be difficult to exaggerate the effect produced by this great journey. Politically it led directly to the founding of what is now the Congo Free State, and indirectly to that scramble for Africa among the European powers which has now left but an insignificant portion of the continent unpartitioned. Stanley returned to London in January

1878, published *Through the Dark Continent* and in 1879 again went out to Africa to found, under the auspices of the king of the Belgians the Congo Free State. Until 1884 this work engaged all his energies. He then returned to Europe, and in 1885 published *The Congo and the Founding of its Free State.* He took part in the Congo Congress at Berlin in 1884–85, and lectured widely, both in Britain and in America, on his African work.

Towards the end of 1886 Stanley was summoned from America to take command of the expedition for the relief of Emin Pasha (see SCHNITZER). On 22d February 1887 he arrived at Zanzibar; on the 25th he, his officers, and the Zanzibari porters, Somalis, and Soudanese soldiers sailed for the mouth of the Congo, where they landed on 18th March. On 15th June the expedition had reached the village of Yambuya, 1300 miles from the sea, on the left bank of the Aruwimi, 96 miles above its confluence with the Congo. Here Stanley divided his forces. He left at Yambuya camp a large number of loads, which were to be brought on as soon as porters were provided by Tippu Tib. The entire force which left Zanzibar numbered, all told, 706 men. Between Zanzibar and Yambuya it was reduced to 649. Of this number 389, including Stanley and five Europeans, made up the advance force, the garrison at Yambuya numbered 129, and a contingent 131 strong was shortly to join the Yambuya camp from Bolobo. Major Barttelot was left in command of the rear column, and on 28th June Stanley set out on his forced march through the forest. It is impossible to follow in detail the story of Stanley's indomitable struggle with almost insurmountable difficulties. Disaster overtook the rear column; its leader, Major Barttelot, was assassinated; Jameson, the next in command, died of fever, and Bonny alone remained at the camp. For many months no news of Stanley reached Europe; then came rumours of disaster; and finally the news that Emin and Stanley had joined hands on the shores of the Albert Nyanza. Into the history of their relations it is needless to enter, as there exists a small library of Emin literature dealing with the subject in all its aspects. The return journey was made by an overland route to the east coast, and Bagamoyo was reached on 4th December 1889. Apart from the main object of Stanley's journey, this expedition established the existence of a vast tropical forest to the west of the lake country, and occupying the northern portion of the Congo basin, as also of the vast snow-capped height of Ruwenzori (18,000 to 19,000 feet). In 1890 Stanley, after recruiting his health in Egypt and the south of France, returned to London, and met with a reception almost royal in its splendour. He was everywhere feasted and fêted; the Royal Geographical Society bestowed on him a special gold medal, and replicas were also presented to his officers on the Emin Relief Expedition; and Oxford, Cambridge, Edinburgh, and Durham conferred on him honorary degrees. His marriage in Westminster Abbey to Miss Dorothy Tennant was a fitting climax. In the following year Stanley visited America and Australia on lecturing tours, returning in the spring of 1892.

His works include, besides those named above, *Coomassie and Magdala* (1874); *In Darkest Africa: or the Quest, Rescue, and Retreat of Emin* (1890); and a novel, *My Kalulu* (1873). See also the article SCHNITZER, and books cited there.

Stanley, THOMAS, translator of Æschylus and historian of philosophy, was the son of Sir Thomas Stanley, and was born at his house of Comberlow in Hertfordshire in 1625. He had Fairfax, translator of Tasso, for private tutor, and studied at Cambridge, passing M.A. in 1641. He also had the Oxford master's degree, though he does not seem to have studied there. He became a member of the Middle Temple, and practised law throughout life, though his best energies were given to literature. He published translations from the Greek, Latin, French, Spanish, and Italian poets; but his great works were the *History of Philosophy* (4 vols. 1655–62) and an edition of Æschylus, with Latin translation and commentary (1663–64). The former deals only with Greek philosophy, and is based on Diogenes Laertius; but it was long a standard work, having been translated into Latin by Leclerc and others. The Æschylus was generally considered to surpass its predecessors (though Stanley was blamed for 'plagiarism' from Casaubon, Scaliger, and others); the best edition was that edited by Butler in 1809–16. Stanley died in London, 12th April 1678. See the Life prefixed to Brydge's edition of his *Poems* (1814–15).

Stanley, VENETIA. See DIGBY (KENELM).

Stanley Pool, a lake-like expansion, in 16° E. long. and 4° S. lat., of the river Congo (q.v.), discovered by H. M. Stanley in 1877. It measures 25 miles in length by 16 in width, and lies 1142 feet above sea-level.

Stannaries (Lat. *stannum*, 'tin'), the mines from which tin is dug. The term is most generally used with reference to the peculiar laws and usages of the tin-mines in the counties of Cornwall and Devon. By an early usage peculiar to these counties, the prerogative of the crown, elsewhere reaching only to gold and silver mines, is extended to mines of tin, which are the property of the sovereign, whoever be the owner of the soil. A charter of King John to his tinners in Cornwall and Devonshire, of date 1201, authorised them to dig tin, and turf to melt the tin, anywhere in the moors, and in the fees of bishops, abbots, and earls, as they had been used and accustomed—a privilege afterwards confirmed by successive monarchs. When Edward III. created his son, the Black Prince, Duke of Cornwall, he at the same time conferred on him the Stannaries of Devon and Cornwall, which were incorporated in perpetuity with the duchy. Their administration is committed to an officer called the Lord Warden of the Stannaries, who has two substitutes or vice-wardens, one for Cornwall and one for Devon. In former times representative assemblies of the tinners (called parliaments) were summoned by the warden under a writ from the Duke of Cornwall, for the regulation of the stannaries and redress of grievances: the last of them was held in 1752. The Stannary Courts are courts of record held by the warden and vice-warden, of the same limited and exclusive character as the Courts-palatine, in which the tinners have the privilege of suing and being sued. They were remodelled and regulated by a series of acts of parliament. Appeals from these courts are now taken to the Court of Appeal, and there is a final appeal to the House of Lords. In Cornwall the right to dig tin in unenclosed or 'wastrel' lands within specified bounds may be acquired by one who is not the owner of the lands, on going through certain formalities, the party acquiring this right being bound to pay one-fifteenth to the owner of the lands. An ancient privilege, by which the Duke of Cornwall had the right of pre-emption of tin throughout that county, has long fallen into abeyance.

Stanovoi Mountains. See SIBERIA, p. 426.

Stanton Drew, a small village of Somersetshire, 7 miles S. of Bristol, with great megalithic remains, especially stone circles.

Staple, the modern form of the Anglo-Saxon word *stapel*, meaning a heap, or regularly piled up accumulation, of goods; hence a place where goods are stored up for sale. In the middle ages, when the term was in common use, a staple meant both the trading-town for particular commodities and the commodities that were wont to be exposed for sale there. The kings of England from the beginning of the 14th century issued various regulations affecting the staple towns for the sale of England's principal commodity in those ages—wool. In 1313 Edward II. enjoined that all English merchants trading abroad, in Flanders, Brabant, and the adjacent countries, should carry all their wool to one staple town in Flanders; from 1343 Bruges was the town that enjoyed this privilege. But the men of Bruges greatly hampered the trade, and put vexatious hindrances in the way of the English merchants trading with the towns that lay farther inland; so that in 1353 Edward III. transferred the staple to England, and shared its privileges amongst half a score of coast towns from Newcastle to Bristol. At the same time all questions in dispute affecting mercantile transactions at these towns were put under the jurisdiction of an officer (one in each town) called the mayor of the staple, who decided all such differences by 'merchant law,' with the assistance of foreign merchants as assessors. The change to England, however, which it was hoped would relieve the English merchant from the vexatious interference of foreign governments and advantage the island country by attracting foreign merchants, proved anything but satisfactory, and from about the year 1362 the staple for English wool was almost constantly fixed at Calais, and remained there down to the year 1558. The Scottish merchants had their staple at Campvere (q.v.) in Holland. But as commerce grew with the lapse of time, it gradually broke down the barriers imposed by the system of staples. This concentration of trade in particular commodities or of particular countries at certain cities and towns was owing to both economic and political reasons. It was a sort of established policy of the Plantagenet kings to regulate trade in the interests of the royal power. Important privileges were accorded to foreign merchants on condition of their agreeing to frequent certain towns for purposes of traffic. This, too, enabled the royal officers of the customs the more readily and easily to collect the revenues of the crown accruing from those sources. And this line of state policy was so far congruent with the requirements of international commerce that it was the means of bringing buyers and sellers together at the same time and in the same place, and that it enabled the merchants trading from or to one town or country, or association of trading-towns, to combine together for their mutual advantage and protection.

Star. See Stars, Orders of Knighthood.

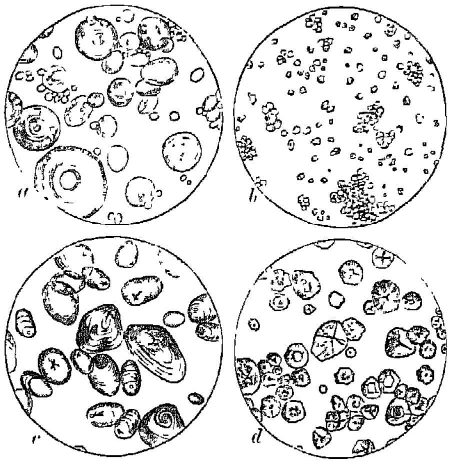
Star Apple (*Chrysophyllum*), a genus of trees and shrubs of the natural order Sapotaceæ. The species are natives of tropical and subtropical countries. The Star Apple of the West Indies (*C. cainito*) is a shrub about 8 or 10 feet high. The fruit is large, rose-coloured, mixed with green and yellow, and has a soft sweet pulp of an agreeable flavour. Other species produce edible fruit.

Staraya-Russa, a town of Russia, 62 miles S. of Novgorod by rail round Lake Ilmen, is remarkable for its salt springs, which attract large numbers of visitors in summer. Pop. 13,537.

Starboard. See Steering.

Starbuck. See Manihiki Islands.

Starch, $C_6H_{10}O_5$. It is one of the essential functions of the leaves of plants to decompose carbonic acid, by the help of sunlight which shines through the chlorophyll, with evolution of oxygen and the formation of starch. The starch becomes converted by a diastatic ferment into sugar, which passes from the leaves to various parts of the plants, and being reconverted into starch, is stored. See Chlorophyll, Leaf, and Seed. It is in this way that fruits and seeds, stems—e.g. that of the sago palm—tubers like the potato, tap-roots, bulbs, &c. become stored with starch. The granules of starch are usually of a rounded form, consisting of a nucleus surrounded by a number of envelopes or layers. Each species of plant has its own peculiar shape of granule which can be recognised under the microscope, but in the same plant these granules differ in size. The smallest size of a granule of oat-starch is ·0001, while the largest sized granule of Tous-les-mois starch is about ·0015 of an inch. In a small book on the *Chemistry of Foods*, by Dr Bell of the Somerset House Laboratory, the reader will find a considerable number of illustrations of starches as seen under the microscope.



Starch Granules:

a, wheat; *b*, rice; *c*, potato; *d*, maize; all magnified 250 diameters. (From Dr Bell's *Chemistry of Foods*.)

Starch has the same elementary composition as sugar, gum, and woody fibre (cellulose). These all belong to a class of substances called carbohydrates, because they could be represented as compounds of carbon and water, as shown by the formula given above, which corresponds to six atoms of carbon and five molecules of water, H_2O. Starch contains no nitrogen, and is thus distinguished from characteristic animal compounds. The peculiar structure of starch granules and the way in which they occur in the vegetable cell permit of their being readily separated from other matters occurring along with them in plants. As usually prepared, starch is either a white glistening powder or it is obtained in irregular prisms which arise from the cracking up of a cake of the dried material. When pressed between the fingers a slight but peculiar sound is produced. Its specific gravity varies from 1·55 to 1·60. Starch is soluble only to a very slight extent in cold water, but when heated in water to above 150° F. the granules burst, and a clear ropy solution is formed which, on cooling, becomes a translucent jelly called starch-paste. This paste gives a deep blue colour with iodine and an orange yellow with bromine, the former being a highly characteristic and delicate test for starch. If a salt of iodine, such as iodide of potassium, is used, the iodine must be liberated either by a drop of strong nitric acid or preferably by a little chlorine water. By the gentle action of nitric acid on starch an explosive compound called *xyloidine* is obtained. At a temperature of about 320° F. (160° C.) starch is converted into *dextrine* or *British gum*, and the same change is produced on starch by the action of dilute mineral acids. Dextrine is usually made on an industrial scale from potato-starch. It is this Dextrine (q.v.) which is the adhesive matter on postage stamps, but it is otherwise largely used in the arts. By the further action of acids on starch *dextrose* or grape-sugar, and also the crystallisable sugar, *maltose*, are obtained. Maltose sugar is likewise produced during the operation of malting by the action of diastase on the starch of grain.

Starch is heard of in England as early as 1511, but was not much used till 1564, when, according to Planché, 'Mistress Binghein Vandh Plasse, a Fleming, came to London, and publicly taught the art of starching. . . . Stubbes falls foul of this "liquid matter which they call starch, wherein the devil hath learned them to wash and dive their ruffs, which being dry will then stand stiff and inflexible about their necks."'

Manufacture.—Starch is manufactured on a large scale in Europe from maize, wheat, rice, potatoes, and from sago-flour. *Maize-starch* is most largely made. The grain contains 65 per cent. of starch and about 14 of gluten and other nitrogenous matters. The Indian corn is first steeped for forty-eight hours in water at a temperature not exceeding 120° F. It is then ground with water by millstones into a milky state, after which it is sieved to keep back the husks. From the sieve the starchy liquid passes into 'runs' or channels made of wood, from 2½ to 4 feet broad and 9 inches deep, in which the starch deposits. It is then removed from the runs and put along with water into vats or tuns (10 feet in diameter and 4 feet 6 inches deep) provided with stirrers, some very weak soda-lye being added. After it is sufficiently stirred the liquid is allowed to settle, when the starch falls to the bottom. At this stage the vats contain a layer of starch, over this a layer of gluten, and above that again a stratum of yellowish water thick with gluten. The starch is again washed with water in the final settling vats, from which, after drawing off the water, it is removed and spread on clean cotton sheeting to be dried in stoves at a temperature between 120° and 130° F. A little chloride of lime is used to bleach maize and other kinds of starch.

Potato-starch.—In manufacturing starch from potatoes, the latter are first washed in machines of various kinds, but of which one of the simplest is a revolving cage-like cylinder with wooden bars. Then follows the grating of the washed potatoes by forcing them against the saw-like teeth of raspers, which, as sufficient water is fed to the machine, reduces them to a paste. In order to separate fibrous and albuminous matters and other impurities, the starch-paste with an addition of water is passed through fine sieves, and at the same time agitated by various arrangements. From the sieves it is received into settling tanks in which the deposit of starch is again washed in clean water. It then descends in a milky stream over an inclined plane, on which the starch is deposited, and afterwards once more washed. A little alum or sulphuric acid is used to assist in the removal of albuminous matters. The starch is dried either on porous bricks or on slabs of gypsum, and for some purposes it undergoes another drying in a hot chamber.

Wheat-starch.—Owing to the large amount of albuminous and other nitrogenous bodies (gluten or its equivalents) which wheat contains, amounting sometimes to more than 15 per cent., the methods of making starch from this grain are a little more complicated than the processes employed to obtain it from other cereals or potatoes. Wheat-starch is made by the old plan of removing the gluten by fermentation, and also by Martin's method of kneading the flour into a stiff dough and washing out the starch with water on a sieve. Good English wheat contains about 69 per cent. of starch, but in this grain the proportion of both starch and gluten varies much.

Rice-starch is prepared by removing the gluten, which amounts to from 7 to 8 per cent. of the seed, by the action of soda in weak solution. The proportion of starch in rice is higher than it is in other cereals, varying from a little under to a little over 80 per cent. The *corn-flours* of commerce are prepared either from the purified starch of maize or from that of rice. These flours, being nearly pure starches, with the flesh and bone forming constituents extracted, are not flours of their respective seeds in the sense that wheat-flour is.

Sago-starch is obtained from the pith of the stems of sago palms (see PALM and SAGO). Most of the sago imported into England is in the form of sago-flour, which is used in the manufacture of household starch and glucose sugar. Besides its use in the laundry, starch is extensively employed in dressing textile fabrics and as a thickener for the colours used in printing calico; also for mounting photographic prints and dusting founders' moulds.

The principal starches prepared for food besides the 'corn-flours' are *Arrowroot* (q.v.), *Tapioca* (q.v.); and *Tous-les-mois*, from the rhizomes of a species of Canna cultivated in St Kitts, West Indies. *Curcuma Starch* is made to some extent in Southern India from the tuberous root of *Curcuma angustifolia*, and is sometimes called by Europeans East India arrowroot. In France starch is manufactured from horse-chestnuts. Paisley is the principal seat of the starch-manufacture in Great Britain, where it is chiefly made from maize. Rice-starch is made on a large scale at Norwich, and wheat-starch at Belfast.

In the United States, where maize-starch was first produced in 1842, the principal manufactories are at Oswego, New York, and at Glen Cove, on Long Island; indeed, these are the largest starch-works in the world. There are over 100 other factories in the Union, some producing potato-starch or wheat-starch, but the most maize-starch; and some 10,000,000 lb. of starch is now exported annually. Maize-starch is manufactured from a large porous-grained Indian corn.

Star-chamber, a tribunal which met in the old Council-chamber of the palace of Westminster, and is said to have got its name from the roof of that apartment being decorated with gilt stars, or because in it 'starres' or Jewish bonds had been kept. It is supposed to have originated in early times out of the exercise of jurisdiction by the king's council, whose powers in this respect had greatly declined when in 1487 Henry VII., anxious to repress the indolence and illegal exertions of powerful landowners, revived and remodelled them, or, according to some investigators, instituted what was practically an entirely new tribunal. The statute conferred on the Chancellor, the Treasurer, and the Keeper of the Privy Seal, with the assistance of a bishop and a temporal Lord of the Council, and Chief-justices, or two other justices in their absence, a jurisdiction to punish, without a jury, the misdemeanours of sheriffs and juries, as well as riots and unlawful assemblies. Henry VIII. added to the other members of the court the President of the Council, and ultimately all the privy-councillors were members of it. The resulting tribunal was, during the Tudor age, of undoubted utility as a means of bringing to justice great and powerful offenders who would otherwise have had it in their power to set the law at defiance. It was independent of a jury, and at that time juries were too easily terrorised by the nobles. The civil jurisdiction of the Star-chamber comprised controversies between English and foreign merchants, testamentary causes, disputes between the heads and commonalty of corporations, lay and ecclesiastical, and claims to deodands. As a criminal court it could inflict any punishment short of death, and had cognisance of forgery, perjury, riots, maintenance, fraud, libels, conspiracy, misconduct of judges and others connected with the administration of the law, and all offences against the state, in so far as they could be brought under the denomination of contempt of the king's authority. Even treason, murder, and felony could be brought under the jurisdiction of the Star-chamber, where the king chose to remit the capital sentence. The form of proceeding was by written information and interrogatories, except when the accused person confessed, in which case the information and proceedings were oral; and out of this exception grew one of the most flagrant abuses of this tribunal in the later period of its history. Regardless of the existing rule that the confession must be free and unconstrained, pressure of every kind, including torture, was used to procure acknowledgments of guilt; admissions of the most immaterial facts were construed into confessions; and fine, imprisonment, and mutilation inflicted on a mere oral proceeding, without hearing the accused, by a court consisting of the immediate representatives of prerogative. The proceedings of the Star-chamber had always been viewed with distrust by the commons; but during the reign of Charles I. its excesses reached a pitch that made it absolutely odious to the country at large; the punishments inflicted on Alexander Leighton, Prynne, Burton, and Bastwick brought matters to a height, and in 1641 a bill was carried in both Houses (16 Car. I. chap. 10) which decreed the abolition of the Star-chamber and the equally unpopular court of High Commission (q.v.). See CHARLES I., LAUD.

Starfishes (Asteroidea), a class of Echinoderms, nearly allied to the Brittle-stars (Ophiuroidea), an account of which is included in this article, and to the Sea-urchins (Echinoidea).

The Common Five-rayed Starfish (*Asterias* or *Asteracanthion rubens*) may be taken as type. It is sometimes seen in shore-pools about the low-water level, but its haunts are on the floor of the sea at depths of a few fathoms. It moves sluggishly by means of suctorial tube-feet on the under surface of each arm. It often feeds on young oysters and other bivalves, but it may live on much smaller booty.

Haeckel compared such a starfish to a colony of five worms, and the comparison is useful. Each arm is anatomically complete in itself; there is a ventral nerve-cord ending in a terminal eye, and united with the nerves of the other four arms in a pentagon around the mouth; there is a blood-vessel above each radial nerve, and a vascular ring above the nerve-pentagon; there is a radial water-vessel in each arm, connected internally with little reservoirs or ampullæ, externally with the suctorial tube-feet, and centrally with a circum-oral water-ring, supplied by a vertical stone-canal which opens on the dorsal surface in a 'madreporic tubercle' between two of the arms; there are two digestive outgrowths or cæca of the gut in each arm; and there are also reproductive organs. Moreover, each arm has a certain independence of life, for a separated arm can grow the other four.

This theory gives us a vivid anatomical conception of the starfish, but the suggestion of the origin of a starfish from a colony of five worms is not justified by the embryological facts. The interpretation which regards a five-armed starfish as a decentralisation of a flattened pentagonal sea-urchin, is more plausible than that which regards the Echinoid as a concentration of a bloated Asteroid.

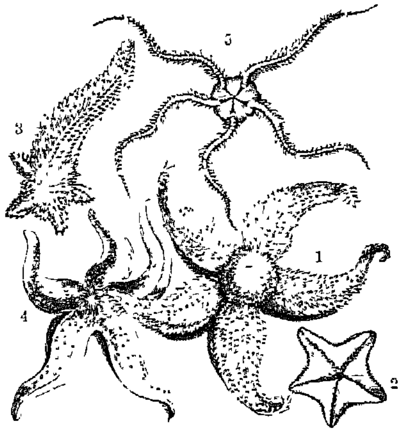


Fig. 1.—Starfishes and Brittle-stars:
1, Common Starfish (*Asterias rubens*); 2, Gibbous Starlet (*Asterina gibbosa*); 3, Common Starfish, reproducing rays; 4, Eyed Cribella (*Cribella oculata*); 5, Lesser Sand-star (*Ophiura albida*). (From Forbes's *British Starfishes*.)

Like most Echinoderms, the starfish is very calcareous. Forming the ventral groove of each arm there are important rafter-like plates called ambulacral ossicles; from the more external mesoderm are developed smaller ossicles, superficial spines, and snapping scissor-like pedicellariæ. The starfish is not very muscular, but the arms can be bent in various ways, part of the stomach can be protruded, and there are contractile elements in connection with the water-vascular system. Besides the five radial nerves and the circum-oral pentagon, there is a diffuse nervous network beneath the ciliated ectoderm covering the body. Thus the skin is diffusely sensitive, and the little red 'eye' at the tip of each arm is certainly sensitive to light. The mouth is in the centre of the ventral surface; from the median stomach a pair of digestive cæca grow out into each arm; from the short tubular intestine between the stomach and the central dorsal anus, two little outgrowths arise, comparable, it is said, to the respiratory trees of Holothurians. There is a distinct, though not spacious, body-cavity, lined by ciliated epithelium, and containing a fluid with some amœboid cells, the brownish pigment of which perhaps aids in respiration.

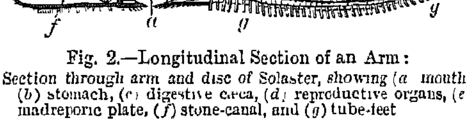

Fig. 2.—Longitudinal Section of an Arm:
Section through arm and disc of Solaster, showing (*a*) mouth, (*b*) stomach, (*c*) digestive cæca, (*d*) reproductive organs, (*e*) madreporic plate, (*f*) stone-canal, and (*g*) tube-feet

When we watch a starfish crawling up the side of a rock we see that scores of soft tube-feet are protruded from the ventral groove of each arm, that these become long and tense, and that their sucker-like terminal discs are pressed against the hard surface. There they are fixed, and towards the attachment the starfish gently lifts itself. The protrusion is effected by the internal injection of fluid into the tube-feet; the fixing is due to the fact that the contained fluid, flowing back again from the tube-feet to the internal reservoirs, produces a vacuum between the ends of the tube-feet and the surface of the rock.

On the dorsal surface, between the bases of two of the arms, there is a complex calcareous sieve, somewhat suggestive of the rose of a watering-pan. Its pores converge into a 'stone-canal,' which, like a complex calcareous filter, extends vertically through the body, and leads into a ring around the mouth. This circum-oral ring gives off nine transparent vesicles and five radial tubes, one for each arm. Each radial vessel lies in the ventral groove of an arm, roofed by the rafter-like ossicles, and gives off internally reservoir-like bladders or ampullæ, and externally the tube-feet. The fluid in the system seems to pass from the radial vessels into the tube-feet, and from the tube-feet back into the ampullæ. It is evident that the water-vascular system is modified for locomotion, but it is likely that it also helps in respiration and perhaps also in excretion. At the end of each arm there is a long unpaired tube-foot which acts like a tactile tentacle. The blood-vascular system is well developed, and in its general course corresponds to the water-vascular system. Respiration is in great part discharged by numerous 'skin-gills,' contractile hollow outgrowths from the skin of the dorsal and lateral surfaces. Of excretion in the starfish we know almost nothing. The sexes are separate but quite like one another; the reproductive organs—branched like elongated bunches of grapes—lie in pairs in each arm; the genital ducts open dorsally between the bases of the arms.

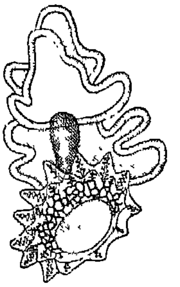

Fig. 3.—Bipinnaria with young Starfish developing within it.

The ova are fertilised in the water. It is said that they occasionally begin to develop without fertilisation. The segmentation is complete, a blastosphere is formed and a typical gastrula. The free-swimming larva, as in other Echinoderms, is remarkably specialised, with two ciliated bands and peculiar arm-like outgrowths. It is known as a Bipinnaria or as a Brachiolaria. The adult is a new formation within the larva, retaining the water-vascular system and mid-gut, but absorbing or rejecting the provisional larval structures. There is also in this indirect development a remarkable change from bilateral to radial symmetry. Parental care occasionally occurs among Asteroids; thus a large Asterias has been seen sheltering its young within its arms, while in Pteraster and some others there is a dorsal brood-pouch. Many Asteroids break very readily, throwing off their arms when seized. The lost parts are slowly regenerated, and strange shapes, especially the 'comet-form,' often result in the course of regrowth. It is even possible that this 'autotomy' of members may sometimes be a means of multiplication.

The commonest European starfishes are species of Asterias or Asteracanthion, Astropecten, Cribella, Solaster, Goniaster. In Astropecten and several related forms the food-canal ends blindly; in Brisinga the arms are very long and arise abruptly from a small central disc, as in Ophiuroids; in Luidia the pedicellariæ are three-bladed instead of two-bladed; and there are many minor differences like the above. There are also considerable differences in external form, witness the many-rayed Solaster, the pincushion-like Goniaster, the flat pentagonal Palmipes. The largest forms are such as *Asterias gigantea*, from the Pacific coast of North America, which measures two feet in diameter, and *Pycnopodia helianthoides*, which measures about a yard in diameter, and has over twenty arms. The majority live in comparatively shallow water, but the Ophiuroid-like Brisinga, the widely distributed Hymenaster, the blue *Porcellanaster cœruleus*, and many others are deep-sea forms. The earliest occurrence of Asteroids is in Silurian strata.

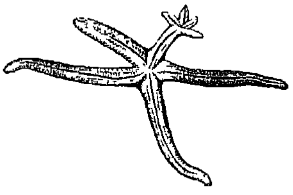

Fig. 4.—Process of budding from one of the arms of *Linckia multifora*. (After P. and F. Sarasin.)

The *Brittle-stars* (Ophiuroidea) differ from Asteroids in the more centralised body, more sharply defined arms, and more active habit. Compared more fully with starfishes, the brittle-stars are more muscular and less limy; the arms do not contain digestive cæca from the gut nor reproductive organs, and are supported by an axis of limy 'vertebral ossicles;' the tube-feet are smaller, apparently tactile and respiratory, and locomotion is effected by the muscular wriggling of the arms; the groove so well seen on the ventral surface of the starfish arm is here closed in by limy plates; the alimentary canal ends blindly; the entrance to the water-vascular system (madreporic plate) is ventral; the larval form is known as a Pluteus. The popular name 'brittle-star' refers to the extreme ease with which the arms break; another common name, 'sand-stars,' refers less happily to their occasional occurrence on the shore; the technical title Ophiuroid describes the snake-like coils of their arms.

The brittle-stars creep about by wriggling their muscular arms. Some are found creeping on the shores at low-tide, but the majority keep to the floor of more or less deep water. On blocks of coral and the like they swarm in enormous numbers, twisting themselves most fantastically about the crevices. They are carnivorous animals, feeding on small molluscs, crustaceans, worms, and much simpler organisms like Foraminifera.

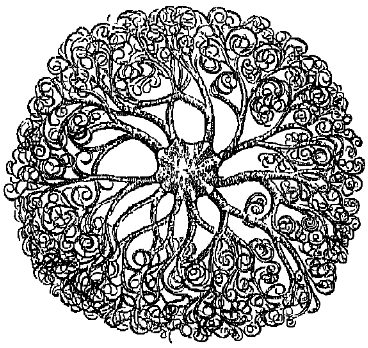

Fig. 5.—The Shetland Argus (*Astrophyton scutatum*). (From Forbes.)

With few exceptions (e.g. *Amphiura squamata*), the brittle-stars are unisexual. In most the eggs are liberated as such, are fertilised externally, and develop in the water; but some species—e.g. *Ophiopholis bellis*, *Ophiacoma vivipara*—produce their young alive (viviparously), and in these cases the genital clefts are enlarged to form distinct brood-chambers. The openings of the clefts admit water, and thus aid in respiration. When the young are born viviparously they are more or less like the parent Ophiuroid, and have no free swimming larval stage, but where the eggs develop freely in the water, the result is a strange swimming larval form utterly unlike a brittle star. This so called 'Pluteus' is fancifully compared to a many-legged painter's easel, the legs being rods of lime which project from the body of the larva. Similar forms are characteristic of sea-urchins (Echinoids). As in other Echinoderms, the development is indirect. It is well known that in the panic of capture the brittle-stars justify their name by giving off their arms with singular facility. This pathological process is doubtless advantageous, for, like other Echinoderms, the brittle-stars have great powers of regeneration. They can grow new arms or new points, and thus recuperate their injuries; and in some species of Linckia and Ophidiaster an isolated arm may produce other arms.

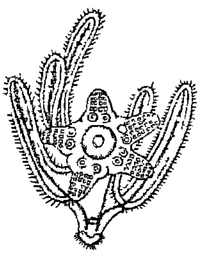

Fig. 6.—Pluteus larva with young Ophiuroid developing within it.

The brittle-stars are world-wide in their distribution, or occur at least in all seas yet dredged. The depth of their habitat varies greatly. 'More than two hundred species are restricted in their range to a zone of thirty fathoms,' but 'sixty-nine species descend below one thousand fathoms, and about eighteen below two thousand.' About fifty fossil species are known Some are said to appear in the Silurian and Devonian, but about these very ancient forms not much is certainly known. In the higher Mesozoic strata, however, they become frequent, and are especially numerous in Jurassic beds.

The Ophiuroids form the most numerous class of Echinodermata, and may be divided into two distinct orders—(*a*) the Ophiurida, with unforked arms, which cannot be rolled up towards the mouth, and usually have distinct limy shields; (*b*) Euryalida, often with forked arms, which can be rolled up towards the mouth, and have not distinct limy shields.

Important Forms.—(1) *Ophiurida.*—Among the commonest British species are the Common Sand-star (*Ophiura texturata*), the Lesser Sand-star (*O. albida*), and the Common Brittle-star (*Ophiocoma rosula*). In North-European seas *Ophioglypha lacertosa* is very common. *Ophiopholis bellis* is viviparous. *Ophiactis virens* divides spontaneously. The very widely distributed *Amphiura squamata* is hermaphrodite, viviparous, and phosphorescent. *Ophiopsila aranea* is another luminous form. *Ophiothrix fragilis* is one of the most abundant species, and *Ophiothrix echinata* is common on Mediterranean shores. Ophiomyxa leads on to the Euryalida, which in its soft skin and general appearance it markedly resembles. (2) *Euryalida.*—The very curious Gorgonocephalus or medusa-headed brittle-star is one of the best-known genera in this division. The arms are repeatedly forked, and as they curl in towards the mouth become intertwined in a living knot of the most fantastic appearance. Euryale is another important genus. One form has been occasionally caught on herring nets off British coasts. They are sometimes called Basket-fish, Medusa-headed Starfish, or Argus Starfish.

Sc. Series, Lond. 1885).

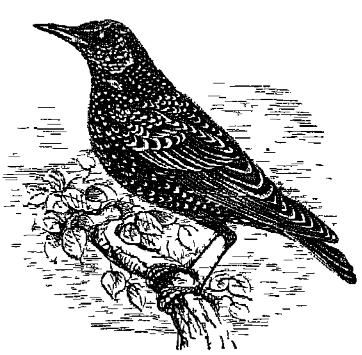
Stargard, the chief town of Further Pomerania, Prussia, on the Ihna, 22 miles by rail E. by S. of Stettin. Pop. 23,738.

Star Jelly. See Nostoc.

Starling, a genus Sturnus, and family Sturnidæ of Passerine birds. The family is a highly characteristic Old-World one, extending to every part of the Eastern continent and its islands, and even to Samoa and New Zealand, but wholly absent from the Australian mainland. The Common Starling (*S. vulgaris*) is a beautiful bird, rather smaller than the song-thrush or mavis, brown, finely glossed with black, with rich metallic purple and green reflections, with a buff coloured tip to each feather, giving the bird a fine speckled appearance, particularly on the breast and shoulders; in advanced age it is more uniform in colour. The female is less brilliant than the male, and has the terminal spots larger. Both sexes are more speckled in winter than in summer. The starling is abundant in most parts of Britain, and nowhere more so than in the Hebrides and Orkneys. It is very abundant in nearly every district of England, but is less common in Cornwall and in Wales. It is found in all parts of Europe, extending even to Iceland and Greenland. To the Mediterranean basin it is a cold weather visitor in enormous numbers; and it is also common in the north of Asia. Starlings make artless nests of slender twigs, roots, and dry grass (often in company with other birds), in hollow trees, in holes of cliffs, under eaves of houses, or, readily enough, in boxes, which are often placed for them in trees or elsewhere near houses. Year after year they return and build in the same spot if the nest has been removed. They lay from four to seven pale-blue eggs, and breed twice, sometimes thrice, in a season. In autumn the young birds join to form flocks, which become augmented by the older birds, until there is a whole cloud of starlings executing aerial evolutions night after night before roosting time. In winter they disperse in search of food. Their food consists of worms, slugs, beetles, fruit, especially elderberries, and in severe weather they eat hips and haws and sandworms and small molluscs. They



Starling (*Sturnus vulgaris*).

are often found following cattle for the insects attending them. The starling becomes very pert and familiar in confinement, displays great imitative powers, and learns to whistle tunes, and even to articulate words with great distinctness. Its natural song is soft and sweet. In Spain, Southern Italy, and Sicily the unspotted starling (*S. unicolor*) is found, and from Asia Minor to North-western India *S. purpurascens* and several other allied species are found. The Rose-coloured Starling (*Pastor roseus*), a crested bird with rose-pink back, shoulders, breast, and under parts, is an annual visitor to nearly every part of the British Islands, and an irregular migrant over the greater part of Europe. In 1875 many thousands visited Italy, following large flights of locusts, and bred in the province of Verona; and similar incursions have often been made into other places. To North Africa it is an occasional migrant. Eastward it extends through Turkestan to India. Its favourite food is locusts, and on this account it is protected in many districts; but in India, in the cold season, it destroys much grain.

Star-nose. See MOLE.

Starodoub, a town of the Ukraine, in Russia, 120 miles NE. of Tchernigoff. Pop. 24,388.

Star of Bethlehem (*Ornithogalum*), a genus of bulbous-rooted plants of the natural order Liliaceæ, nearly allied to Squills and Hyacinths.

Star of Bethlehem (*Ornithogalum umbellatum*).

The species are pretty numerous, natives almost exclusively of the eastern hemisphere, many of them of the Cape of Good Hope, and some of the south of Europe. The Common Star of Bethlehem (*O. umbellatum*), a native of France, Switzerland, Germany, the Levant, &c., is very common in flower-gardens. Its flowers are large, six to nine, in a corymbose raceme, white and somewhat fragrant. *Gagea lutea*, formerly *O. luteum*, with yellow flowers, is found in some parts of Britain in woods and pastures.

Star of India. See INDIAN ORDERS.

Stars are in general distinguished from other celestial bodies by their fixity of position in the celestial sphere, by the scintillation of their light, and by the fact that they show no appreciable size even under the highest telescopic power. The first quality renders them of great use in that department of astronomy which relates to accurate time-keeping and to measures of latitude and longitude. They form fixed points of reference whose place from their minuteness can be very accurately determined; and as they are far removed from terrestrial and even solar influence we can refer the motions of the earth and other members of the solar system to them as to unvarying landmarks. Themselves immovable, they determine for us our own movement. It is true that many possess minute motions of their own, but these, as we shall see, are so small as in most cases to affect but little in *any moderate time* the accuracy of such observations. This practical fixity of the stars enables us to determine two fixed points in the sky called the north and south *poles* of the heavens. Our Pole Star (q.v.) is not far removed from the first of these. Stars near these points are but little affected by the diurnal motion of the heavens, moving with it in *small* circles, while stars in the Equator (q.v.) move with great rapidity, requiring to complete the entire circuit of the heavens in the same time (twenty-four hours) as the others take to traverse their shorter paths. Thus the changing aspect of the heavens is confusing to an observer at first; but on attentive watching it is seen that all the various speeds and paths of the stars result from one simple motion—viz. the apparent revolution of the whole sky once in every twenty-four hours, as if it were a vast hollow ball hung on opposite points at the two poles. The observer looks as from the centre of this ball, and were it not for the earth intercepting his view would see stars on all sides, below as well as above him. At sea or in a sufficiently extensive plain he will see almost exactly one-half of this sphere, the earth hiding the other. A celestial globe represents this sphere, but is necessarily examined from *without*, while the sky is seen from *within*, which must be remembered in using such globes.

Owing to the sun's yearly motion the stars present different aspects at successive times. In June we see nearly one-half of the sky at midnight. By December the sun, pursuing his annual track, has gained a position among the stars we saw at June midnight. They are above the horizon when the sun is in the meridian at noon. At midnight in December we therefore see the stars in the other half of the heavens. At intermediate seasons the condition of things is of course intermediate also. Speaking generally, the starry sky at midnight on the first of any month is the same as that visible at ten o'clock in the evening of the first of the following month, while the ten o'clock aspect in the first case has of course moved to eight o'clock, and so on.

On the inner surface of the sky sphere the stars are irregularly scattered in groups called Constellations (q.v.). From these groups the stars are named by adding a letter or number to the name of the group. The Greek alphabet is used for the brighter stars—α denoting the brightest, β the next brightest, and so on. Roman letters are used when the Greek ones are exhausted, and afterwards numerals. Sometimes, however, the stars are named by their number from some catalogue, with the initial letter of the observer or of the name of catalogue, and the hour of right ascension (see Vol. I. p. 475) in which the star stands. So great a variety and confusion exists in this nomenclature as to be a serious trouble to beginners, and better arrangements in regard to it are much to be desired. In 1891 arrangements were nearly completed for the charting of the stars by a uniform series of telescopic photographs of the entire heavens. In this great work all civilised nations are uniting with an energy promising success. It is expected to contain when finished all stars down to the 14th magnitude.

The Scintillation (q.v.) or twinkling of the stars, by which they are easily distinguished from the planets, is due to disturbances in our atmosphere, combined with the fact that the stars are to us mere luminous *points*. It is magnified by the telescope, and becomes often then sufficient to transform the star into something like a tangled mass of worsted. The various points on the surface of a planet, the sun, or the moon are similarly affected, causing an indistinctness of telescopic vision, which when the air is much disturbed renders accurate observation impossible. But the star, being *one* point of light, twinkles *as a whole*, while the planet, sun, or moon, being even in the smallest case *many* points, does not twinkle as a whole, and the *average* of its rays gives a steady impression to the eye. Scintillation is most observable on nights when the atmosphere is disturbed, and always greatest at the horizon, being least at the zenith and on quiet nights.

Stars are classed in *magnitudes* according to their brilliance. The 1st magnitude includes the brightest class, only some twenty-four in number, the 2d magnitude the next brightest class, and so on, descending in order of brightness to the 15th or even the 17th magnitude, where we encounter the present limit of telescopic vision. At first this classification was most arbitrary, astronomers differing as to the magnitude to which many stars should belong. Hence a decimal notation was introduced, and stars were classed as 1·5 magnitude, 2·3, 4·6, &c. This must not, however, be confounded with an obsolete notation found in some old books, in which 1·2 mag. meant a star between 1st mag. and 2d, but nearer 1st than 2d, and 2·1 meant the same, but nearer 2d than 1st. The regular instrumental measurement of star-magnitudes is an entirely modern work, proceeding rapidly still. Professor Pickering of Harvard has published (1891) two catalogues, together including more than 25,000 stars whose magnitudes are instrumentally determined, and other astronomers are at work in the same field. A rough guide to ordinary estimates is furnished by the fact that stars barely visible to a good eye are classed in mag. 6, while telescopic stars range from mag. 7 to mag. 15 or 16. Arcturus is nearly 1·0 mag. Pollux and Regulus are an average 2d mag. β Arietis is a shade above 3d mag.

Three explanations may be given for this great variety in brilliance among the stars: (1) that they are all at nearly the same distance from us, and are in themselves different in size or brightness; (2) that they are of nearly equal brightness, but ranged at very varied distances; (3) that they vary both in lustre and distance. The first view has long been obsolete, belonging to the infancy of astronomy; the second, though equally erroneous, is still to be found treated in many text-books as if it had some foundation, no doubt because it forms a theoretical basis for the *star-gauging* carried out by the Herschels (q.v.). The third view is unquestionably the correct one, as will more clearly appear when we examine the measured distances of the stars. There must also be considered the probability that space is not perfectly transparent, and may entirely absorb the light of a star, if its distance from the observer be great enough. If this were the case it would help to account for the observed variety in stellar light. It is at least remarkable that the number of faint stars is so much greater than of bright ones, the former exceeding the latter by millions.

Besides this variety between separate stars there are remarkable changes in the light of some stars from time to time. These are known as *Variables*. The number known is continually enlarged by fresh discoveries, and is now several hundreds. This variability is almost always *periodic*; but the length and form of the periods are strikingly different for different stars. *o* Ceti, or *Mira*, as it is called, requires 331 days 8 hours to accomplish its changes. For about a fortnight it is nearly mag. 2, decreasing for three months it becomes invisible, remains so for five months, and then gradually increases for the rest of its period. Algol, or β Persei, has a period of 2 d. 20 h. 49 m.; but its actual change from mag. 2 to 4 is accomplished in 3½ h. η Argus, again, varies from mag. 1 to 6 in seventy years. The so-called 'new' stars appearing from time to time are possibly only extreme instances of this variability. A noted example is the 'Nova' (or new star) of 1572, which reached such brightness as to be visible at mid day in November of that year, but immediately began to diminish, entirely disappearing by March 1574. It is probably *not* identical with the temporary stars of 945 and 1264 A.D. Several similar appearances are known. In August 1885 a 'Nova' appeared in the nucleus of the great Andromeda nebula. About the 6th mag. when first seen, it steadily faded, until by February 7, 1886, it was only of mag. 16. On February 1, 1892, another *nova* of mag. 6 was pointed out in Auriga by Mr T. D. Anderson of Edinburgh. Its place is R.A. 5 h. 25 m. 3 s., dec. + 30° 21′. Within two months it had grown very faint, decreasing since March 9 by half a mag. per day. Its spectrum shows many bright lines, including those of hydrogen and sodium. As to the cause of these outbursts and the other minor fluctuations of the variables there has been much speculation. The passage of attendant meteor-swarms in front of the star, the changes in its atmosphere, positive collision of stars or meteor-swarms, passage of the star behind the edge of a nebula owing to its parallax—these and other explanations have all been advanced; but as yet no satisfactory theory has been given. The spectroscope has revealed in some 'Novas' outbursts of glowing gas; but the cause of such outbursts remains as yet unrevealed. The analogy of the solar spot period (see SUN) would seem to show that solar physics holds the key to this strange problem, our sun being really a slightly variable star.

Variety in *colour* is as great among the stars as variety in light. Comparing Sirius with Betelgeuse this is easily seen. The investigation into this subject is as yet in its infancy, and we may here only note that *very* red stars are never bright, and that the two constituents of a binary star usually are of different colours. Blue or green stars of *marked* colour are also never found alone, but always as members of a close double star.

The measurement of the *distance* of the stars, one of the most difficult problems presented to the human mind, has been also one of its greatest triumphs. It was one of the strongest objections to the Copernican system that if the earth moved as Copernicus said, then the stars would appear to move also, as trees and houses appear to move when seen from a train in motion, *unless indeed the stars were at an inconceivable and impossible distance.* The evidences for the motion of the earth were too strong to be long disputed, and the alternative of the inconceivable distance of the stars had to be admitted. Thus men became familiarised with the *thought* of immense distances, and soon began efforts to *measure* them. The movement of the earth transfers it every six months from one extremity to the other of a line 180,000,000 miles in length. So enormous is the distance of the stars that this change of place in our observatories has hardly any effect on the direction in which we view them. If a star is directly overhead on the meridian when we are at one end of this immense *base-line* it is still overhead when we have arrived at the other end. *Some* minute change, however, there must be, and to measure this astronomers set themselves. In 1805 Piazzi published some results, only to be disproved. Pond and Brinkley in England disputed concerning each other's results, coming to no definite conclusion. Their work, combined with that of Struve at Dorpat in 1820, showed that the change of place looked for—called Parallax (q.v.)—was even smaller than had been supposed, in fact inappreciable to the instruments of that day.

Finally Bessel of Konigsberg, furnished with a fine *heliometer* by Fraunhofer, found in 1840 that the star 61 Cygni showed a *parallax* of 0″·3483, since raised by modern observation to 0″·475. This placed 61 Cygni at a distance = 600,000 times that of the sun from the earth. Struve found about the same time a parallax of 0″·26 for the star Vega, a value since slightly diminished. Henderson also found for α Centauri, a bright southern star, a parallax of about 1″·0, since corrected to 0″·75, a distance equal to 4⅓ *years'* journey of light. The year's journey of Light (q.v.) is now used as the unit in which to express star distance. The distance expressed thus is easily found from the parallax by the following equation: $\frac{3\cdot202}{p} = d$, where p is the parallax, as usually given, in seconds of arc, and d = the distance required. The number 3·202 is a constant depending on the velocity of light. Succeeding these early observers, Auwers and Brunnow in Europe, and C. A. F. Peters in the United States, continued this great work, and in our own day Professor A. Hall, of Washington, and Drs Ball, Gill, and Elkin, in Britain and at the Cape of Good Hope, have wrought diligently in the same field. We give below a table of a few of the more interesting stars, with their parallaxes and distances:

Star.	Parallax.	Distance in Light-units.	Observers.
α Centauri	0″·75	4·3	Gill and Elkin.
61 Cygni	0″·47	6·80	Ball.
Arcturus	0″·127	26·41	C. A. F. Peters.
Vega	0″·18	17·78	A. Hall.
Polaris	0″·076	42·45	C. A. F. Peters.
Aldebaran	0″·516	6·20	O. Struve.

Since 1889 Professor Pritchard of Oxford has employed photography in determining stellar parallax with considerable success. But very much yet remains to be done in this field of research.

From what is said above it is evident that the stars are distributed through all space, as far as we know it. To a cursory glance they appear to be capriciously scattered, but more minute observation shows traces of arrangement, though we are not yet able to state distinctly the law governing it. The Galaxy (q.v.) or Milky Way forms a ring in the heavens, entirely consisting of minute stars, and as we pass away from this ring the stars become much less abundant. The Herschels laid the foundation for this important discovery by their *star-gauges*. A telescope of 18 inches aperture, 20 feet focus, and a magnifying power of 180, giving a field of view 15′ in diameter, was used in all these. The process consisted in directing this instrument to a part of the sky and counting the stars in its field. This repeated hundreds of times gave a fair idea of the average number of stars in a circle of 15′ diameter at all parts of the sky. It was found that at 90° from the ring of the Galaxy this number was 4·15, at 45° from it 10·36, at 15° 30·30, and in the ring 122·00. Sir W. Herschel considered this to indicate that our sun was one of the stars of the Galaxy, which extended on all sides of us as a flat disc of stars. This view, however, presupposes that the stars in this disc-like cluster are somewhat uniformly distributed, a supposition which has little to support it. The Galaxy may
sidered as what it appears, a ring of
latively near one another and vastly distant from us. The whole question remains still unsettled, awaiting more numerous measures of stellar *absolute* parallax than we yet possess.

In particular parts of the sky stars gather in clusters. The Pleiades, Hyades, and Præsepe are examples of loose clusters of comparatively bright stars. Telescopes reveal marvellous groups, such as that in Hercules, which contains in very small space *thousands* of stars, spreading at the edge of the mass into curious curved *sprays*, an arrangement seen also in less closely packed groups. These clusters are quite distinct from Nebulæ (q.v.), and form still a puzzle to the astronomer. The nubeculæ form a very curious instance of a clustering *mixture* of nebulæ and stars. In the case of all these clusters, and even of groups less closely compacted, it is probable that a physical connection binds the various members together. The five intermediate stars of the 'Plough' are known to be moving together, in the same direction and with sensibly equal speed. And this grouping is evident in many other cases. But the laws governing and producing it remain yet unknown.

We have alluded here to star motion, called by astronomers *Proper Motion*. This, although hardly affecting the places of the stars in the sky as marks of reference, is distinct and even measured in the case of very many stars. An annual motion of this kind amounting to 6″ of a great circle of the heavens is accounted large, only some three or four stars exceeding this speed, which would require more than 300 years to transfer the star a distance in the sky equal to the moon's diameter. Although so minute in *apparent* amount, these motions are in reality of a speed inconceivable by us. The star Groombridge 1830 has a real velocity of more than 200 miles per *second*, although annually shifting its place in the sky by only 7″·03; 61 Cygni has a proper motion of 5″·12; a small star 1584, xxiii.^{h} Cordoba Catalogue, has recently been shown to have a proper motion of 6″·205, while many others have motions of much less amount. Part of these motions is due to the solar movement in space (see SUN), which has been calculated from them.

Double and binary stars were first discovered by Sir William Herschel, and the known number is noted now in thousands, and is continually increasing. There are stars so close as to appear single to the eye, or even, in many cases, to considerable telescopic power, but which, when sufficiently magnified, are seen to consist of two or more separate stars. In some cases no known telescopic power suffices to show the double separate, but the periodical *doubling* of certain lines in its spectrum alone reveals its duplicity. In other cases a single star may show such irregularities in its proper motion as to lead to the suspicion that it is attended by a *dark* companion, whose presence is only indirectly revealed to us by the effect it has in disturbing its luminous neighbour. This is the case with Sirius (q.v.) and Procyon, the companion of the former having been actually discovered as an orb of feeble light, after Bessel had pointed out the probability of its existence. Other stars are also surmised to have companions of this kind. Some of the double stars appear to have no physical connection between their components. Others undoubtedly form *systems*, of two or more suns revolving in periods round their common centre of gravity. These periods vary from 1159 years in the case of 61 Cygni to 10·8 years in that of δ Equulei. When the distance from us and period of such a 'double' are known, together with the dimensions of its orbit, its mass can be calculated, on the supposition that it is controlled by the force of gravitation.

In studying the *physical nature* of the stars, modern, unlike ancient and mediæval, science, assuming that the universe is *continuous*, has considered the laws governing terrestrial matter to obtain throughout the visible universe. It was therefore easy, once the question of stellar distance was partly answered, to reach the conclusion that the stars are really *suns*. For they have that in common with our sun, and even with our candles, that they emit *light*, and their light, when analysed, exhibits all the qualities of that emitted by luminous bodies in our laboratories. When their masses are calculated they are found to form bodies of the same order of magnitude as our sun. *α* Centauri (a 'double') has a mass twice that of the sun. 61 Cygni only equals $\frac{1}{7}$ the solar mass. Judging not by direct measurement of mass, but by distance and relative *brightness*, the star Arcturus is 10,000 times more luminous than our sun, and may have a volume equal to 1,000,000 suns. Other stars, either very brilliant or very distant, range in the same order of magnitude, though too much reliance should not be placed on these calculations, which are liable to large errors and discordances.

These investigations prepare us to expect that the stars are similar in materials and in history to our own sun. When the spectroscope (see SPECTRUM) is applied to examine their light this expectation is confirmed. The star Aldebaran shows the spectral lines of hydrogen, sodium, magnesium, iron, tellurium, antimony, calcium, bismuth, and mercury, indicating that these elements exist in its atmosphere in the vaporous state. The examination of numbers of stars confirms this, so that we know the stars to be of material similar to that composing our earth. The problem before astronomers is therefore now to determine the physical state of the matter composing the stars, and the history of their construction. Through Kant and Laplace the idea had become familiar that nebulæ and stars represent different stages of star history, and that different stars correspond to different steps in the process of star *life*, if we may use the expression. Though certainly not yet *proved*, much of modern discovery confirms this view. There is no distinct line between stars and nebulæ. From the cloudy mist of the Orion nebulæ to the sparkling point of Vega or Sirius a gradation of forms may be traced with no sensible break.

Rutherfurd of New York, in 1863, first classified the stars according to their spectra into three groups: (1) Red and golden stars; (2) white stars with lines in their spectra; (3) white stars (as he supposed) without lines. In 1865 Secchi commenced also to classify, ultimately adopting a division into four types, which, though altered by Vogel in name, remains the standard classification of the stars. *It is as follows:*

I. Continuous spectrum, with four heavy hydrogen lines. White stars, as Sirius and Vega.
II. Closely resembling solar spectrum. Yellow stars. Aldebaran and our Sun.
III. Red stars. Fluted bands, *fainter towards the violet end.*
IV. Faint, deep red stars. Fluted bands wider than in III., and *fading towards the red.*

Two prominent explanations are given of these types. The first is that they represent the various stages of star history in order, Class I. containing stars newly formed and excessively hot and brilliant, while Class IV. contains stars cooled down nearly to extinction. The other explanation, due to Lockyer, is that Class III. represents an earlier stage in star history than either I. or II., showing, in fact, the fainter beginning of stellar luminosity; while Class IV. represents the closing period of the star's life as it approaches extinction. Lockyer has on these lines attempted a full classification of the nebulæ and stars, considering all to have their origin in swarms of meteorites (see METEORS), with which he supposes space to be everywhere peopled, and whose collisions, abrasions, and condensations give us ultimately all celestial bodies. This theory has grave objections, and is certainly not established as fact, but it has the merit of being an attempt to unite a vast variety of stellar phenomena under one intelligible principle. We therefore give Lockyer's development of Secchi's classes, with his explanations.

I. Radiation lines and flutings chiefly. Nebulæ and stars with bright line spectra.
II. *Mixed radiation and absorption chiefly. Red stars. Bright* flutings—i e. bands fading—towards the violet.
III. Line absorption chiefly.
IV. Few strong lines. Hottest stars. Central point of star life.
V. *Resembling group* III.; but stars *cooling.*
VI. Carbon absorption chiefly. Stars cooling to extinction.

New stars, on Lockyer's theory, are produced by the sudden collision of swarms of meteors, variable stars by the revolution of two or more swarms, which periodically mingle and collide; and in other ingenious ways various stellar features are accounted for. Time and future observations must be waited for before these explanations are either wholly accepted or rejected. Other eminent scientists strongly object to Lockyer's conclusions. In particular, Croll contended that all evidence goes to show that the physical universe had a beginning not as scattered meteorites, but as immense solid masses moving with a finite velocity, whose collisions formed the first step in the evolution of the various heavenly bodies. Caution in accepting any such theories is, however, very desirable.

Clerke's *History of Astronomy in the 19th Century*, and *The System of the Stars* (1890); *Proceedings Royal Society*, vol. xliv., No 266, being the Bakerian Lecture, 1885, by Lockyer; and Croll's *Stellar Evolution*. See also the articles ASTROLOGY, ASTRONOMY, ZODIAC, &c.

Stars and Stripes. See FLAG, p. 665.

Star-stone, a kind of Sapphire (q.v.).

Start Point, a projection of the coast of Devon, 8 miles S. of Dartmouth, forming the south-eastern extremity of the county. It is crowned by a lighthouse (92 feet), whose light, 204 feet above high-water, is visible for 20 miles.

Starvation. See FAST, Vol. IV. p. 559.

Starwort, or STITCHWORT (*Stellaria*), a genus of plants of the natural order Caryophylleæ, having

Greater Stitchwort (*Stellaria Holostea*).

a calyx of five leaves, five deeply-cloven petals, ten stamens, three styles, and a many-seeded capsule opening with six teeth. The species are numerous, and several are very common in Britain, annual and perennial plants, with weak stems and white flowers, which in some are minute and in others are large enough to be very ornamental to woods and hedge-banks, as in the Wood Starwort (*S. nemorum*) and the Greater Starwort (*S. Holostea*). To this genus the common Chickweed (q.v.) is now generally referred.

Staten Island, (1) a beautiful and picturesque island, 5 miles SW. of New York, washed by both the Upper and Lower Bay, and separated from Long Island by the Narrows and from New Jersey by the Kill van Kull and Staten Island Sound. Area, 55 sq. m.; pop. (1880) 38,991; (1890) 51,693. Its shores are dotted with villages, and its heights crowned with villas. At its eastern point Forts Richmond and Wadsworth guard the entrance to the Narrows. The island constitutes the southernmost county (Richmond) of New York, and on the north shore possesses a home for old sailors.—(2) An Argentinian island separated from the south-east point of Tierra del Fuego by Le Maire Strait (40 miles). It is long (45 miles) and narrow in shape, with steep coasts penetrated by deep fiords, and rises to nearly 3000 feet. Snow covers it almost all the year. The island received its name in 1616 from Cornelius Schouten in honour of the 'Staaten' or States-general of Holland.

State Papers. See RECORDS.

State Religion. A state religion and a national religion are two different things. A nation may, with more or less of universal concurrence, accept a certain type of religion—as the people of the United States for the most part accept Christianity—yet they may not commit to their government the task either of representing officially or of maintaining financially their religion. In that case it is a national but not a state religion. Wherever, on the other hand, we witness either establishment or endowment committed to the government—even if, as in Ireland till 1869, the religion thus favoured is very far from being national—there we have the spectacle of a state religion. Now such a spectacle almost invariably presents itself to our view on the first emergence of any people from tribal confusion into national order. The previous multiplicity of local gods and diversity of religious ideas became fused together into a conglomerate state religion, and then were compacted by time and by priestly labour into a sort of incoherent unity. As to any rights of the individual conscience to worship according to its own private judgment, such a notion had not so much as dawned upon men's imagination. It thus becomes interesting in studying this subject to watch the first emergence of the chief historical nations of the ancient world into organised states; and the earliest naturally to reach this high degree of development were the crowded populations whom abundance of food and water drew together in the great river-basins of the East. China, India, Mesopotamia, Egypt accordingly present us with the first 'states' about which anything is known; and in each case we are confronted with a state religion either patronising or patronised by the civil power. In ancient China, for instance, public worship was regulated down to its minutest details by six ministers of state, who were responsible even for the sacred music and religious dancing. The emperor alone might offer sacrifice to the supreme spirit; the nobility might do homage to the various subordinate spirits of the earth; the high officials to the spirits of house and home, and so on, in ever-descending order. Even the soothsayers, magicians, and spirit-charmers were reckoned among public functionaries of the state. Nor did the reforms effected by Confucius (500 B.C.), nor yet the uprise of two sects, the Tâoists and the Buddhists, alter in any way this Erastian character of the Chinese system. It was therefore, and is still, a state religion in close combination with, and subordination to, the civil power.

A similar phenomenon appears among the crowded races which inhabited ancient Mesopotamia. There, too, the supreme head of the state religion was the king; and to such an extent was he predominant that he alone could penetrate into the innermost sanctuary, he alone could offer sacrifice for the whole people; and his palace stood pre-eminent and alone and solid, as if built for eternity, on the sacred platform whence rose towards heaven the terraced tower of Bel. It is therefore from the ruins of the palaces at Nineveh and Babylon, and not from those of the temples, that the records have been recovered which unfold to us the sacred history of this remarkable form of state religion; displaying to us the gradual amalgamation of a hundred tribal beliefs, the ultimate emergence of a Sennacherib or a Nebuchadnezzar to rule, like some incarnation of divine despotism, over all the prostrate nations, and the absolute predominance of the civil over the ecclesiastical power.

Singularly enough, both in India and in Egypt we have the exact contrary of all this. We find there two forms of state religion, in each of which a priestly caste has gained the supremacy over the regal power. In India (as is well known) a religion which began with the lay poets who composed the Vedas emerged from an obscure period at last completely organised on a caste system; and this system assigned irrevocably the first place to the priesthood and the second place to the secular authorities. In ancient Egypt the same relation between the two powers may be observed. There, too, the priesthood is predominant, and kings hold the secondary place. It is the temples which seem built for eternity. The royal palaces have disappeared; or if anything of royalty has remained it is in their tombs—those palaces of the buried kings which the state religion has consecrated with its symbols and covered thickly over with its rubrics from the 'Book of the Dead.' Here, indeed, as in ancient Mesopotamia, the local gods long held sway, and suffered at last agglomeration into the state religion. But the greater state deities were immensely more powerful. They were endowed with vast estates; they employed thousands of labourers, agents, scribes, overseers; they even maintained armies and flotillas of their own; and should any luckless sceptic too openly express his views he was dragged before the pitiless idol in some dark judgment-hall, and expiated his offence in the flames. Thus the Egyptian state religion dominated the entire life of the people, and for long centuries reigned in uncontested supremacy.

When we cross the sea, however, and disembark in imagination among the bright and mobile populations of southern Europe, we soon find that these vast sullen state religions of the eastern river-basins have been left behind. The gods of ancient Greece were as Bohemian and passionate as their worshippers, and no crushing priestly tyranny could find a footing among its small and quarrelsome communities. Yet even there, as childish fancies about Olympus and its happy denizens hardened into dogma, and nursery legends became endeared to the people and fixed in beautiful forms of epic, dramatic, and statuary art, then here, too, a state religion came into being. To ridicule the gods became perilous, even to an Aristophanes; to mutilate their images became an unpardonable crime; and to replace them by other and worthier conceptions of divine things was a treason which even a Socrates must expiate by his death. In more grim and serious Italy the mingled native and Greek theology became characteristically transmuted into downright law. Offences against the state religion were supposed to bring down on army and navy, on agriculture and commerce, the anger of a justly indignant heaven. And as for any such unheard-of novelty as a catholic or world-wide religion, unacknowledged as its own even by any subject state—still more, for any preposterous claim to worship according to each man's private conscience—away with people possessed of such ideas 'to the lions!' For Christians, therefore, and all state heretics of that sort there was but one answer to be made, *non licet esse vos*, you have no right to exist, you have placed yourselves outside the protection of the Roman empire.

With the conversion of Constantine (313 A.D.), of course, all this was entirely changed; but it was only changed by the parts being reversed. The state religion had now become Christian; and paganism was ere long held to have no right to exist. It is true that with Christianity a new and gentler spirit had found entrance, and that a day might certainly be foreseen when men would cease to persecute and to be persecuted for religion; but that day did not, in fact, come for more than a thousand years. Under the imperial legislation of Justinian the orthodox alone possessed the full privileges of citizenship. And even when the Roman empire was broken up at all points by the irruption of the barbarians, and everything else became changed, still the old-world system of state religions remained unchanged. The Mohammedans, who broke in from the south-east, have always regarded intolerance as a sacred duty; and the Teutonic tribes, who broke in from the north-east, accepted as a matter of course, along with Christianity, its traditional outward forms. Thus, Clovis (500) established the new religion in his Frankish kingdom; Charlemagne (800) even drove the Saxons to conversion at the point of the sword, and with his 'missi,' or royal commissioners, inspected and managed church affairs throughout his wide dominions; and the English Heptarchy, gradually blended into unity, combined in intimate connection the authorities of church and state, without any suspicion that they might one day turn against each other.

But the dangers of such a feeble patchwork of state religions, covering the face of Europe, were obvious and manifold. There was first the insidious danger of 'Simony'—i.e. of a corrupt use of patronage by the laity. Then there was the danger of violent destruction of small state-churches in detail by the fierce and greedy barons of the neighbourhood; and lastly, there was the yet larger peril looming in the future, that each kingdom might finally set up a state religion for itself, and thus hopelessly break up the unity of Christendom. To meet and cope with all these dangers some powerful churchman of large ideas was urgently required, and such a man providentially appeared (1050) in Hildebrand (Pope Gregory VII.). Under his vigorous rule all the existing state religions of Europe were crushed and cramped together into a sort of imperial religion; and for two centuries (till 1300) it seemed as though one all-embracing empire religion were destined to swallow up and destroy all the minor state religions of the world. But when the vast war waged by the papacy in the Crusades had ended in ignominious failure, and when the insensate ambition of men like Innocent III. and Boniface VIII. had roused both France and England to resistance, that great movement of return to state religions (in the proper sense) began which culminated at last in the Reformation. And then the effect of prolonged and obstinate resistance to all change, and of desperate recourse to fire and sword and fraud and treachery, in maintenance of a despotic system in the church which the free strong nations of the north would not endure, was seen in a general break-up of Christendom.

The first thought naturally was to revert to the previous long-tried system of state religion. But when that seemed reduced to an absurdity in the Augsburg settlement (1555) of *cujus regio ejus religio*—making the church an aristocracy instead of a despotism, and every petty duke and count a pope in his own dominions—the tormented nations had recourse to the sword. Germany was torn to pieces and ruined for two hundred years, France was steeped to the lips in blood, Spain and Austria were silenced, the Netherlands thrown into revolt, and England plunged into her great rebellion, till out of the seething strife between papal religion and state religion there gradually emerged a third form—democratic religion. It began, naturally enough, in Switzerland—at Zurich and Geneva. It permeated and honeycombed, to their ultimate downfall, the despotisms in church and state which 'concordats' had conspired to establish; till at last the various acts of toleration in England, the secular 'Constitution' of the United States, and the French revolutionary enactments of 1789 and 1830 completed the transformation of every state religion throughout Europe into a congeries of virtually free churches—sometimes with, sometimes without, a survival from the past in the shape of a central establishment fully tolerating all its neighbours. Thus, at the present moment, England and Scotland retain, along with absolute toleration for every other form of religion, modified state churches; while Ireland—like the United States—has none. France accepts, as a religion recognised and maintained by the state, every communion which numbers 100,000 adherents—those at present receiving state-payment being Roman Catholics, Protestants, Jews, and (in Algeria) Mohammedans. In Belgium the state does not interfere with the internal affairs of any religious body, but it subsidises the Roman Catholics, the Protestants, and the Jews. In the German empire there is universal toleration, but the various states subsidise their religious communities in various ways. In Denmark there is full toleration for all, but the state religion is Lutheranism; and the same arrangement prevails in Sweden and Norway.

The most prominent example of a surviving state religion, with intolerance for all other forms of faith, is to be found in Russia, where the orthodox Greek Church reigns supreme and dissent is severely persecuted. In Austria-Hungary there is liberty for all, but the recognised religions are those of the Roman Catholics (the dominant church), the Greeks, the Protestants, the Armenians, and the Jews. Even in Greece there is full toleration, though the state religion is that of the Greek Church. In Italy, 'by the fundamental law of the kingdom' in 1870, the state religion is Roman Catholic, but there is now complete toleration for other forms of faith. In Spain and Portugal the state religion is also Roman Catholic, and toleration is very limited. In Holland Protestants, Roman Catholics, and Jews are subsidised by the state, but there is toleration for all. In Turkey the state religion is Mohammedanism. In Switzerland there is absolute freedom for every form of faith. On the whole it would seem that the system of state religion is, by the advancing tide of democracy, threatened with extinction; but that some countries retain it, as an axis round which other communions may crystallise, or at least as a security against Atheism, Ultramontanism, and other dangers which the future may have in store for democratic states.

The special relation of the church and state in the Jewish theocracy will be gathered from the articles BIBLE (Vol. II. p. 118), JEWS. The growth of nonconformity in England led to keen controversy between the defenders and the opponents of church establishments; and, especially since the foundation of the 'Society for the Liberation of Religion from State Patronage and Control' in 1844, there has been an increasingly outspoken demand for the disestablishment, with or without the disendowment of the Church of England, especially in Wales. For the 'Erastian Controversy,' see ERASTUS; for the 'Bangorian Controversy,' see HOADLY; for the rivalry between the church and dissent in the schools, see EDUCATION. The great Scottish 'Voluntary Controversy' (see UNITED PRESBYTERIAN CHURCH) between the defenders of the church and dissenters was at its height in 1829–34; the Free Church (q.v.) long insisted on the establishment doctrine in a modified form. The disestablishment of the Irish Church (1869) rendered the controversies as to the established churches in the other parts of the United Kingdom more acute. For other controversies bearing more or less directly on the question, see CATHOLIC EMANCIPATION, JEWS (for the removal of Jewish disabilities), CHURCHYARDS, HOOKER, NEWMAN, OATH, PERSECUTION, TEST ACTS, TITHES, TOLERATION; and the articles on Independents, Friends, and other Nonconformists, as well as that on the Church of England. Of the British colonies, it may be generally said that those which have representative government have no state church, though provision has long been guaranteed for Catholic education in Quebec province. And in most of the Crown colonies also the disestablishment of the Church of England, and the withdrawal of state aid where there was concurrent endowment, has been carried out, especially since 1868. In India there is a small Anglican establishment for the army and other English residents. In the articles on the several countries notes will usually be found as to whether there is an established church or not. And for the view that the church should finally be merged in the regenerated state, see ROTHE (RICHARD). Of the copious literature, see, of works favourable to establishments, Selden, *On Tithes* (1618); Coleridge, *Church and State* (1830); Stanley, *Church and State* (1870); the present writer's *Dissent in relation to the Church of England* (1871); Warburton, *Alliance of Church and State;* Maitland, *The Voluntary System* (1837); Moore, *Englishman's Brief for his National Church* (1880); Selborne, *Defence against Disestablishment* (1886); Hughes, *The Old Church and the New* (1891); Story, *The Church of Scotland, Past and Present* (1891). Unfavourable: Locke, *Letters on Toleration* (1689); Wardlaw, *National Establishments* (1839); Baptist Noel, *Church and State* (1849); Vaughan, *English Nonconformity* (1862); Miall, *The Voluntary Principle* (2d ed. 1850); Skeats, *Free Churches* (1869); *Religious Republics* (1869); *The Case for Disestablishment* (1884). Of books on the general subject of church and state, the following may be consulted: De Marca, *De Concordantia Sacerdotii et Imperii* (fol. 1641); Franck, *Philosophie du Droit Ecclesiastique* (1864); Zeller, *Staat und Kirche* (1873); Geffcken, *Church and State* (Eng. trans. 2 vols. 1877); A. Taylor Innes, *Church and State* (1890). On details: Tiele, *History of Ancient Religions* (Eng. trans. 1877); Speir, *Life in Ancient India* (1856); Reville, *Religions des Peuples non-civilisés* (1883); Sayce, *Ancient Babylonian Religion* (1887); Maspero, *Life in Ancient Egypt* (trans. 1892).

States-general (Fr. *états généraux*), the name given to the representative body of the three orders (nobility, clergy, burghers) of the French kingdom. In the time of Charlemagne and for seventy years after his death there were assemblies of clergy and nobles held twice a year to deliberate on matters of public importance. There is no trace of any national assembly in France properly so called earlier than 1302, when the States-general or representatives of the three orders were convened by Philip the Handsome in his quarrel with Pope Boniface VIII. The States-general, however, though their consent seems in strictness to have been considered requisite for any measure imposing a general taxation, had no right of redressing abuses except by petition, and no legislative power. Under Charles VI. and Charles VII. they were rarely convened. Louis XIII. convoked them, after a long interval, in 1614, but dismissed them for looking too closely into the finances; and from that time down to the Revolution (1789) they were never once summoned to meet. As soon as they did assemble—the clergy, 291; noblesse, 270; *tiers état*, 557 (nearly half lawyers)—the Third Estate, after inviting the noblesse and clergy to sit with them, on the advice of Sieyès, constituted themselves a National Assembly (17th June). About 150 of the clergy joined them (22d June), and nearly 50 of the nobles, with Philip of Orleans, on 25th June; the rest followed by the king's command two days later.

The title States-general was likewise borne by the representatives chosen by the provinces of the old republic of the Netherlands to exercise sovereign power. They met at the Hague (1593–1795), and voted by provinces. The name is retained for the existing legislative body or parliament of the kingdom of the Netherlands. See also ESTATES.

States of the Church. See CHURCH (STATES OF THE).

States' Rights, in the history of the United States, refers to a construction of the Constitution and to a doctrine based on that construction, to the effect that the several states of the Union were and are independent sovereigns, federate to attain and maintain certain common interests by means definite and limited, and that to them alone allegiance is due by their citizens; that the general government is not raised by the Constitution to the position of a national sovereign, but is merely a diplomatic agency whose acts must be ratified by the independent states from whom its authority is derived; and that these are each entitled to judge of any infractions of the Constitution, and to nullify any acts of congress which they may hold to be in excess of its authority, or even to secede from the Union. It will be evident that this position rests on a false assumption, for not one of the thirteen colonies which first formed the United States ever possessed an independent sovereignty, nor could sovereignty have been attained by them otherwise than by united action; so that in 1776 it was a single possessor of the entire sum of sovereign powers that came into being in the person of thirteen states manifesting the will and force to hold such power as one national state within all the territory known as the United States; nay, each several state jurisdiction is actually dependent on that federal will and force, and the sovereign powers exercised in the government of each state, as well as those exercised in and for the whole country by congress, are derived from the will and force of all the states, existing as one integral sovereignty. See Dr J. C. Hurd's *Union-State* (New York, 1890).

Invalid as the doctrine appears, however, it has played a prominent part in the country's history, and brought on finally the war of secession. Its earliest appearance was during the troublous years that followed the French Revolution, when the unsettled condition of affairs in that country alarmed congress and led it to pass certain Alien and Sedition laws, authorising the president to remove from the United States aliens whose presence might seem to him of public danger, and to punish sedition and seditious publications. This action of congress appeared to some to overstep its powers, and in 1798 the legislatures of Kentucky and Virginia protested vigorously on States'-Right grounds; but the other states dissented from the position thus for the first time formally assumed. In 1811, and again in 1819, the question was raised in connection with the United States Bank Charter, Henry Clay, and afterwards the state of Maryland, maintaining that congress had no power to incorporate companies or to create a bank. So far the advocates of States' Rights had spoken only; in 1832, in South Carolina, they made the first attempt to carry the principle into action (see NULLIFICATION); in 1860-61 (South Carolina again the first), and in the years which followed, the seceding states carried out that principle, of which they assumed the truth, to the full. The war of secession was the logical outcome of the disputes and agitation of sixty years; with its failure it may be presumed that the doctrine which inspired it, at least in its extreme form and as a factor in practical politics, fell too.

Statice. See PLUMBAGINEÆ.

Statics, the branch of dynamics which treats of equilibrium. The ordinary Balance (q.v.) is one of the most important of statical instruments. With it we balance the weight of a body of unknown mass against the combined weights of a number of standard masses, and so determine the unknown mass in terms of recognised units. The general principle of statics is that which describes the condition of equilibrium amongst a number of given forces. The condition is that the vector sum of the moments of the forces about any and every point vanishes. It is more usual in text-books to break this statement up into two, which admit of ready application. The first is that the sum of the components of the forces along each of three non-coplanar directions vanishes; and the second that the sum of the moments of the forces about each of these three directions also vanishes (see MOMENT). These two rules give six conditions for the equilibrium of a rigid body, three for translation, and three for rotation. Used in combination with other roots, the word statics always implies equilibrium or relative rest. Thus we have Hydrostatics (q.v.) dealing with the equilibrium of fluids, and Electrostatics (see ELECTRICITY) treating of the equilibrium of electrified bodies. See also DYNAMICS and KINETICS. Minchin's *Statics* (4th ed. 1890-91) is the best English treatise on the subject. See also GRAPHIC STATICS.

Stationers' Hall, the hall of the 'Master and Keepers or Wardens and Commonalty of the Mystery or Art of the Stationers of the City of London.' The Company was incorporated in 1557, and had until the passing of the Copyright Act in 1842 an absolute monopoly, as all printers were obliged to serve an apprenticeship to a member of the Company, and every publication, from a Bible to a ballad, was required to be 'Entered at Stationers' Hall.' This registration is no longer compulsory, but the practice of registering is still useful in making good claims of Copyright (q.v.). The series of registers of books entered for publication, commencing in 1554, is of enormous value in the history of English literature. A transcript of these from 1554 to 1640 has been published by Professor Arber, in 5 vols.

Stationery Office, an office in London established by the Lords of the Treasury in 1786, for the purpose of providing for the supply of books, stationery, &c. for the government offices at home and abroad. Its main function, however, is in making contracts for the printing of all reports and other matters laid before the House of Commons. The duties are performed by a controller and assistant-controller, a storekeeper, and about thirty clerks or other subordinate officers. There is a branch establishment in Dublin. The Lords of the Treasury make the principal appointments, but clerkships are open to competitive examination.

Stations (Lat. *statio*), a name applied in the Roman Catholic Church to certain places reputed of special sanctity, which are appointed to be visited as places of prayer. The name is particularly applied in this sense to certain churches in the city of Rome, which, from an early period, have been appointed as churches which the faithful are particularly invited to visit on stated days. The names of these churches are found on the several days in the Roman missal prefixed to the liturgy peculiar to the day. The word, however, is employed in a still more remarkable manner in reference to a very popular and widely-received devotional practice of the Roman Catholic Church, known as that of 'The Stations of the Cross.' This devotion prevails in all Catholic countries; and the traveller often recognises it even at a distance by the emblems which are employed in directing its observance—the lofty 'Calvary' crowning some distant eminence, with a series of fresco-pictures or bas-reliefs arranged at intervals along the line of approach. But the same series of images or pictures is ranged round most Roman Catholic churches, usually starting from one side of the high altar and ending at the other. These representations, the subjects of which are supplied by scenes from the several stages of the Passion of our Lord, are called Stations of the Cross, and the whole series is popularly known as the *Via Calvarii*, or Way of Calvary. The origin of this devotional exercise, like that of local pilgrimages, is traceable to the difficulty of access to the Holy Places of Palestine, consequent on the Moslem occupation of Jerusalem and the Holy Land; these representations being designed to serve as some analogous incentive to the piety and faith of the Christian worshipper of our Lord in His Passion. The number of the so-called 'stations' is properly fourteen, although in some places fifteen, and in others, as Vienna, only eleven; but, whatever may be their number, the subject of all is a sort of pictorial narrative of the Passion. The devotional exercise itself is performed by kneeling at the several stations in succession, and reciting certain prayers at each. Forms of prayer are prescribed to those who can read. The poor and ignorant recite the Lord's Prayer and Hail, Mary! all being directed to fix their thoughts in grateful memory upon 'the sufferings which each representation describes our Lord as having undergone, in atonement for the sins of mankind.' Many 'indulgences' are granted to those who, having duly repented of their sins, shall piously perform this exercise. One Anglican church at least, that of Frome in Somerset, has sculptured Stations of the Cross.

Statistics, that branch of Political Science which has for its object the collecting and arranging of facts bearing on the condition, social, moral, and material, of a people. The collecting of such facts, and the taking of censuses for military purposes, have been in use since the earliest times: King David numbered his people, and Egyptians and Romans had censuses. But the treatment of the statistics of all nations as a branch of study dates from the time of Conring (1606-81), in Germany, to whose distinguished successor Achenwall of Göttingen (1719-72) the name of the study (Ger. *Die Statistik*) seems to be due. As distinguished from the early and simple 'descriptive statistics,' in which the figures were but illustrations to the text, a more scientific arithmetical or mathematical method may be credited to Sussmilch (1707-67), whose work had been simplified by the working out of probabilities and averages in connection with mortality tables and otherwise, by Petty and Halley in England, and others. But most of all to Quételet (q.v.), the great Belgian statistician, is the science indebted for its present standing. The principle lying at the foundation of the science as ultimately developed is that the laws which govern nature, and more especially those which govern the moral and physical condition of mankind, are constant, and are to be discovered by the investigation and comparison of phenomena extending over a very large number of instances. Accidental diversities tend to neutralise each other, their influence diminishing as the area of investigation increases; and if that area be sufficiently extended, they so nearly disappear that we are entitled to disregard them altogether. While the length of a single life cannot be counted on, an average of 1000 or 10,000 lives gives us a constant quantity, sufficiently near the truth to answer the purposes of insurance companies. Even the acts which are the most purely voluntary as regards individual men have been found to be subject to laws which, in respect of the masses which make up society, are invariable in like circumstances, and discoverable.

The science of statistics has a twofold relation to political and social economy. The facts collected by the statist are the bases on which political economy rests; their application to social and economical problems is an appeal from imagination to fact. But the statist must be guided by the political economist in what direction to extend his investigations: without political economy we should have had no statistics. There have been keen and useless controversies as to whether statistics is an adjunct to other sciences, and a mere method, or an independent science; and as to whether it should limit its scope to national and social phenomena (in which acceptation the word 'demography' has been proposed as a descriptive name), or should be extended into meteorology and other natural sciences. It is impossible to give any convenient and comprehensive classification of the multifarious topics that fall within the sphere of the statistician—population, trade inland and foreign, wealth, currency, prices, banks, social conditions, the people, &c.

There was a kind of statistical bureau in France in Sully's days; such an institution was permanently set ageing in 1800. But the perfecting of statistical methods owes more to the foundation of the Belgian statistical bureau under Quételet in 1831. Since then most civilised lands have devoted much time, labour, and money to collecting and tabulating their statistics—France, Italy, and Germany, and the United States being perhaps remarkable for the fullness and systematic organisation of their statistical returns. What is done in England is not managed by any one central bureau or board, and is less systematic, though very varied and valuable (see BLUE-BOOKS).

There was a statistical section added to the British Association in 1833, and the Statistical Society of London was established in 1834. Under Quételet's influence a great statistical congress was brought together at Brussels in 1853, and like congresses have been held since, usually at intervals of three years, in one of the chief European towns. The *Journal of the Statistical Society* and the *Journal de la Société de Statistique* of Paris appear regularly; and in 1885 an 'International Institute of Statistics' was founded, which publishes a *Bulletin de l'Institut Internationale de Statistique.*

See the articles in this work on CENSUS, MORTALITY (BILLS OF), INSURANCE, GRAPHIC METHODS, AVERAGE, PROBABILITIES, VITAL STATISTICS; the relevant sections in the articles on Great Britain and the several countries, as also such articles as COTTON, RAILWAYS; annuals like the *Almanac de Gotha*, *Statesman's Year-Book*, and such almanacs as Whitaker's; Mulhall's *Dictionary of Statistics* (1883; new ed. 1891-92); Kolb's *Condition of Nations* (Eng. trans. 1880); Hübner's *Statistische Tafel* (annual); Webster's *Trade of the World* (1880); Block's *Traité Théorique et Pratique de Statistique* (1878); and other works and articles about statistics by modern statisticians like Bodio, Haushofer, Kries, Gabaglio, Farr, Giffen, and Sir Rawson Rawson.

Statius, PUBLIUS PAPINIUS, Roman poet, was born at Naples 40 to 45 A.D., son of a poet and schoolmaster at Naples and at Rome. From early youth addicted to poetry, he gained prizes in the contests at Naples, won the Alban olive-wreath three times, and flourished as a court poet in the favour of Domitian, whom he flattered almost as shamelessly as his rival Martial himself. He lost the wreath of oak-leaves at the Capitoline competition in 94, and thereafter retired to Naples with his wife Claudia, where he died about 96. His chief work is the *Thebais*, an epic in twelve books on the famous theme of the struggle between the brothers Eteocles and Polynices of Thebes. The poem took twelve years to write, yet its construction is slovenly enough—one episode alone occupying one-sixth of the whole poem. It is tedious as a whole, and marred by over alliteration and allusiveness, but is redeemed by passages of exquisite art. Of another epic, the *Achilleis*, only a fragment consisting of one book and part of another remains. His *Silvæ*, or occasional verses, apparently half improvisations, are thirty-two in number, extending to nearly 4000 lines, mostly in hexameters. They have the freshness and vigour, together with the artistic imperfections, of unpremeditated effort, but, putting aside the flatteries to the emperor, they show not seldom a spark of the right Promethean fire. The quick touches of pathos, on separation and death, and on the sweet charm of childhood, would alone preserve some of these slight poems from oblivion.

The *editio princeps* of the epics appeared in 1470, of the *Silvæ* in 1472. Throughout the middle ages the fame of Statius was great, as readers of Dante (*Purg.* xxi.) will remember. The best editions of the *Thebaïs* are by O. Müller (books i.-vi. only, 1870) and Ph. Kohlmann (1844); of the *Achilleïs*, by Kohlmann; of the *Silvæ*, by Jeremiah Markland (1728) and by Baehrens (1876).

Statuary. See SCULPTURE.

Statute of Frauds. See FRAUD.

Statutes. A statute expresses the will of the legislature. It takes effect from the first moment of the day of its passing. Except in Scotland, it remains in force though obsolete; and when repealed it is not revived by the repeal of the repealing act. It is always to be construed 'according to the intent of them that made it.' Primarily, technical words are understood in their technical, other words in their popular sense. When precise and free from ambiguity, they receive their literal meaning and grammatical construction, whatever may be thought of the wisdom or policy of the enactment. But language is so imperfect, and general words are so elastic and open to such varieties of meaning and force, that the literal construction often does not express the real intention. Where such a doubt arises it is necessary to consider what was the earlier law, what its defect, and what the proposed remedy and its object; in other words, to examine the history of the act and the context. The whole act is read, every part in the sense best harmonising with the rest. The preamble is especially invoked to explain what is doubtful. Earlier acts, though expired or repealed, and even later ones on the same or analogous subject, are resorted to, also, for light. The title, marginal notes, and punctuation are disregarded, and so are all statements of members of the Houses and draftsmen as to what was intended.

The scope and object of the act being thus ascertained, it generally receives a beneficial construction which best 'suppresses the mischief and advances the remedy.' Sometimes words receive an unusual stretch of meaning; for instance, a married woman living apart from her husband would be included in the expression a 'single woman,' where the object of the act was to give the mother of an illegitimate child a claim on the father for its support. So a generic term usually includes species which did not exist when the act was passed. Thus, an act of George II. against copying copyright engravings includes photographic copies, and one of William IV. against 'furious driving' applies to bicycles, though photography and bicycles were not then known. In the same spirit all devices resorted to for evading a law, or misusing powers which it conferred, are defeated by including such attempts within it.

To give effect to the intention expressions are sometimes strained; for instance, 'beyond the seas' is read in an old act as equivalent to 'out of the British dominions.' Sometimes the collocation of the words is altered, or they are rejected altogether, or even words are interpolated. But such modifications are made only when obviously necessary in correction of a careless text which did not make sense or was incomplete as it stood.

Beneficial construction is applied less freely to penal acts. There is a reluctance to supply in them the defects of language, or to eke out their meaning by doubtful inferences. Where a word or phrase is open to reasonable doubt, the benefit of the doubt is given to the subject. An omission, also, would probably not be supplied; but the extreme strictness of construction of former times has now materially given way to the paramount rule that a statute is to be expounded according to the real intention. Acts which impose on the subject burdens or formalities, or otherwise restrict natural liberty, or create monopolies, or confer privileges are construed in the same spirit as penal acts. The language of local and personal acts, which invest persons or bodies with rights and privileges for their own profit or interfere with the rights of others, is regarded as rather that of its promoters than of the legislature, and is consequently construed most strongly against them.

Certain constructions are always rejected, if the language can admit it. Any which would lead to inconvenience and injustice or absurdity would be avoided as probably foreign to the real intention. For this reason a construction which made an act operate retrospectively on vested rights would be avoided; and so would any which conflicted with international law—a construction, for instance, which extended a criminal statute to a foreigner for an offence committed abroad. Again, an act would not be read as affecting the prerogative rights or property of the crown, unless the intention was plainly expressed or irresistibly inferable. A like reluctance is felt to attribute an intention to oust the jurisdiction of the superior courts, or to extend that of new or inferior tribunals and authorities.

If two statutes, or two passages in one, are contradictory, the earlier is abrogated by implication. But, as self-contradiction was probably not intended, such a construction is rejected unless inevitable, or unless there be inconvenience or incongruity in both enactments being in force, or the later would be inoperative if the earlier was not repealed. Special and local acts are unaffected by general acts inconsistent with them, being regarded as not in the contemplation of the legislature when making the general act.

Another and most important axiom is that no change of the law is intended beyond the specific object immediately in view. Words and phrases, therefore, however comprehensive literally, are so restricted as not to affect any general principles of law. An act, for example, which empowered 'any' justice to try a case would not include a justice who was incapacitated by interest or otherwise from trying it. To confine an act to its immediate object, it is often construed as operative only between certain persons, or under certain circumstances, or for certain purposes only. Thus, an act which made a bill for money lost at play 'void to all intents and purposes' would not affect the validity of the bill in the hands of an innocent indorsee for value, but would apply to it only when in the hands of the drawer or of others with no better title.

It follows that incidents are sometimes found imported into an act which give it an operation different from its strictly grammatical meaning. Thus, where a power is conferred, everything in the way both of right and obligation which is indispensable to its due exercise is tacitly included by law. When, therefore, a statute enacts that a public officer 'may' do some act of a judicial or public nature, it also by implication directs that he 'must' exercise the power whenever the occasion arises; and if its exercise may prejudice a person, it involves the further duty of first giving the latter an opportunity of being heard against it.

When a statute grants a right subject to certain formalities, compliance with such prescriptions is essential on pain of invalidation. But when the prescriptions relate to a public duty, and invalidation for neglect would be unjust to persons who have no control over the defaulting official, without promoting the object of the act, non-compliance does not invalidate. In the former case the act is imperative, in the latter directory only. A penalty for doing something implies a prohibition; this makes the prohibited act unlawful; and all contracts connected with illegal acts are void.

There are some minor rules of interpretation which hardly call for notice here. Some will be found in the Act 52 and 53 Vict. chap. 63. But it may be mentioned, in conclusion, that usage, or a long and general public or professional practice, sometimes impresses on an enactment a meaning not in accord with the natural sense of the words, but which is nevertheless accepted as conclusive.

Staubbach, Fall of. See Lauterbrunnen.

Staunton, capital of Augusta county, Virginia, in the Shenandoah valley, 136 miles by rail WNW. of Richmond. It is the site of the state lunatic and deaf and dumb and blind asylums, and contains several women's schools, large ironworks, and flour and planing mills. Pop. (1890) 6975.

Staunton, Howard, chess-player and Shakespearian scholar, was born in 1810, studied at Oxford, early settled down to journalism in London, and died June 22, 1874. His victory in 1843 over M. St Amand made him the champion chess-player of his day. To this subject he contributed the following works: *The Chess-player's Handbook* (1847), *Chess-player's Companion* (1849), *Chess-tournament* (1851), *Chess Praxis* (1860). His edition of Shakespeare appeared in six volumes (1858-60), with a number of textual emendations so excellent as to give him rank among the best contemporary critics. Another edition (3 vols. 1858-60) was enriched by 824 illustrations by Sir John Gilbert. Staunton also published in 1866 a careful photo-lithographic fac-simile of the first folio text of Shakespeare. Another useful work was *The Great Schools of England* (1865).

Staurolite (Gr. *stauros*, 'a cross;' *lithos*, 'a stone'), a silicate of alumina with ferrous oxide, magnesia, and water, crystallises in trimetric forms, and often occurs as twinned cruciform crystals in certain slates and schists. It is reddish, yellowish brown, or brownish black.

Stavanger, the most important town in the south-west of Norway, stands on the southern side of Bukken Fjord, 100 miles S. of Bergen. It has two harbours, entered annually by about 490 vessels of 180,000 tons burden, and derives its importance from its connection with the fisheries of the adjacent coast. The town dates back to the 9th century at least, but has been frequently destroyed by fire, and is now quite a modern place. The cathedral, a Gothic structure, was founded by an English bishop (Reinald) in the 11th century, but was restored in 1866. Of late years it has become a favourite rendezvous of tourists to Norway, 3500 stopping here in 1890. Pop. (1891) 23,930.

Stavesacre (*Delphinium staphisagria*), a species of Larkspur (q.v.), a native of the south of Europe. The seeds have been used in medicine from ancient times; they contain the alkaloids delphinine, delphinoidine, and delphisine, and a considerable quantity of a fixed oil. The seeds are poisonous, causing great depression of the nervous and circulatory systems, with vomiting and purging. They are officinal in the British pharmacopœia, and from them an ointment is made which is used to kill lice, this being its sole therapeutical application at the present time.

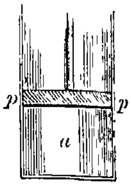
Stavropol, a town laid out in 1776 on the northern slopes of the Caucasus and on the principal highway between Russia and Persia. It has broad streets and good stone houses, is the seat of a Greek-Catholic bishop, has railway connections with Rostoff near the mouth of the Don, and is a rapidly growing place, with active industries and a brisk trade in cattle, corn, tallow, hides. Pop. 36,561.—The *government* of Stavropol has an area of 26,492 sq. m. and a pop. of 657,554.

Stays. See TIGHT LACING.

Stealing. See THEFT.

Steam. Steam is the vapour of water. When dry it is invisible and transparent like air, and not to be confused with the semi-liquid cloud which comes from the chimney of a locomotive. When superheated (see below) it changes the characteristics of a vapour for those belonging to what is known as a 'perfect gas' (see GAS). The development of steam is naturally enough connected popularly with a high temperature, but the two things do not necessarily go together. Water (or snow, or ice) gives off vapour or steam at *every* temperature—a low temperature not preventing the formation of steam, but only decreasing its density. The only limit to this evaporation is when the air surrounding the water (or snow, &c.) is already saturated with vapour of the maximum density which the water can give off at the existing temperature. Thus, water at 32° F. will give off vapour of a pressure equal to 0·085 lb. per square inch; but if the air above it is already saturated with vapour of that density the tendency of the particles of water to fly apart is exactly balanced by the pressure of the vapour on its surface, and no more evaporation takes place. While no atmospheric pressure can prevent the water or ice passing into vapour, the previous presence in the air of vapour of the required density (even when so small as in the instance just given) entirely stops it.

Suppose *a* to be a cylinder, and *pp* a piston moving steam-tight within it; and suppose also that the end of the cylinder above *p* is open to the atmosphere, and that below *p* there is in the cylinder a perfect vacuum. There is then a downward pressure upon the piston equal to the whole force of the atmosphere, or about 14·7 lb. per square inch. If now a little water could be introduced into the bottom of the cylinder without admitting any air, a quantity of vapour would rise from it, and press with more or less force on the lower side of the piston so as to sustain a portion of the weight of the atmosphere. How much vapour would rise, and how much elastic force or pressure it would exert, would depend upon the temperature of the water and cylinder.



At 32° F., as we have already said, the vapour in the space *a* would exert a pressure equal only to 0·085 lb. per square inch. If the temperature were raised to 80° more vapour would rise until its pressure became about 0·5 lb. per square inch; at 102° the pressure would be 1 lb.; at 162°, 5 lb.; at 193°, 10 lb.; and so on, until at 212° F. the pressure would be 14·7 lb., or exactly equal to that of the atmosphere. When this point has been reached it is evident that the piston will be *in equilibrio*, the pressure beneath it being exactly equal to that above. At each intermediate point the downward pressure on *pp* is equal to the pressure of the atmosphere *minus* the pressure of the steam below the piston. So far as the piston is concerned the conditions are therefore the same as if the vacuum had been impaired by the introduction of a certain quantity of *air* below *pp*; but there is this difference between the two cases—if the space *a* had been occupied by rarefied air, then, by forcing the piston down and compressing it into less space, its density would increase until its pressure became equal to or greater than that of the external air. With steam, however, if the piston were depressed, *and if the temperature of the steam were preserved the same*, instead of its pressure being increased, a portion of it would be liquefied, and the remainder would have the same pressure as before.

It is at 212° F. that water in an open vessel begins to boil—i.e. the vapour rises rapidly and in volumes, being able to displace the atmosphere (see BOILING). In this state it is usually called *steam*; but there is no essential difference between steam at 212° and steam at 60°. The steam rising from boiling water in an open vessel is of the same temperature as the water—viz. 212°; but, notwithstanding this, it contains a great deal more *heat*. This heat is employed in (to use popular language) forcing asunder the molecules of the steam, and thus causing it to occupy so much greater a bulk as steam than as water. It does not make itself known by the thermometer (for which reason it is called *latent* heat), but its existence and amount are known by other means (see HEAT). In speaking of the pressure of steam we have given it in pounds per square inch above a perfect vacuum, or as what is called an *absolute* pressure. This must be carefully distinguished from pressures (as often given) in pounds *above atmospheric pressure*. According to the method we adopt, which is the more scientific one, steam of 14·7 lb., or one atmosphere, exactly balances the pressure of the air, and can therefore do no work against it; while, if the other nomenclature had been adopted, steam of 14·7 lb. *above* atmospheric pressure would have been really steam of *two* atmospheres pressure.

When a cubic inch of water is converted into steam at the ordinary pressure of the atmosphere its volume is increased to 1645 cubic inches—i.e. a cubic inch of water becomes nearly a cubic foot of steam of one atmosphere. If the steam is produced at any greater pressure, its volume will be very nearly inversely as that pressure; at two atmospheres it would occupy about 855 cubic inches; at four atmospheres, about 457 cubic inches.

When water is boiled in an open vessel neither the temperature of the water nor that of the steam rising from it ever rises higher than 212°, however hot the fire; the heat as it enters is carried off in a latent state in the steam. But under pressure the temperature of both can be raised to any degree. If, when the water and steam in *a* (above) came to 212°, the application of heat were still continued, more steam would continue to rise, and, the pressure on the under side of the piston being now greater than that of the air above it, the piston would begin to ascend; but suppose it held in the same position by force, the upward pressure of the steam would be found rapidly to increase until it would soon require a weight of 14·7 lb. per square inch to keep it down, showing that the pressure of the steam was now equal to twice that of the atmosphere, or to 29·4 lb. per square inch. If at this point the temperature of the water and steam were examined, it would be found to be very nearly 250° F. When the absolute pressure of the steam reached 50 lb. its temperature would be 281°; at 100 lb., 328°; at 150 lb., 360°, and so on.

From the numerous experiments made on this subject some very important general conclusions may be drawn. Of these one—which will be evident from the figures just given—is that the pressure of steam increases at a far higher rate than the temperature (doubling the temperature increases the pressure *nearly 23 times*), which shows the extreme danger of continuing to apply heat to a vessel from which the steam is not allowed to escape. The bursting force would soon become such as no vessel could resist. Another important conclusion is that for every temperature there is a corresponding density of steam produced. This steam contains a definite amount of latent heat, and exerts a certain uniform pressure on every side of any vessel in which it may be contained. The following table shows the relation between these values for steam of several different temperatures:

T.	*p*.	H.	V.	*v*.
32°	0·085	1091·8	3390·0	211,536
104°	1·06	1113·7	312·8	19,519
158°	4·51	1130·1	80·02	4,993
212°	14·7	1146·6	26·36	1,645
248°	28·83	1157·5	14·0	874
293°	60·4	1171·2	6·992	436
350°	145·8	1190·4	3·057	191
401°	250·3	1204·1	1·838	115

T, Temperature in degrees Fahrenheit; *p*, absolute pressure in pounds per square inch of the steam at that temperature. H, Total heat of the vapour above 32° F. at that temperature (according to Regnault's experiments), in *thermal units*. A thermal unit (772 foot-pounds) is the quantity of heat which will raise 1 lb. of water 1° F. at or near its temperature of greatest density, 39·1° F. The specific heat of water increases slowly as the temperature rises, so that 1 thermal unit will not raise 1 lb. of water *quite* so much as 1° at high temperatures. V, Volume in cubic feet occupied by 1 lb. of steam; *v*, number of times which volume of steam exceeds that of same weight of water.

The relations between temperature and pressure in the foregoing table apply only so long as the steam is in contact with the water from which it is generated. Once away from the water its temperature may be raised without altering its pressure. Steam which has received additional heat in this way is called *superheated* steam. It approximates to the condition of a perfect gas, and therefore follows nearly what is known as Boyle's or Mariotte's Law, its volume varying always inversely as its pressure. By this law steam which occupied 1 cubic foot at 20 lb. absolute pressure would occupy 4 cubic feet at 5 lb., and half a cubic foot at 40 lb. absolute pressure. But steam, as commonly used in the steam-engine, is not superheated, but used under the conditions given in the table. It is then called *saturated* steam, and differs sensibly from the condition of a perfect gas. If the pressure (p) be given in pounds per square inch, and the product (pv) of pressure and volume in foot-pounds, then the formula, $\log. (pv) = 4·675 + ·061 \log p$, gives results accurate enough at all ordinary pressures, and can be very easily applied. The volume, instead of increasing inversely as the pressure, increases less rapidly; the difference, though not very great, is so large that it has to be taken into account in all calculations as to the efficiency and behaviour of steam in a steam-engine.

It might naturally be expected that it would take much more heat or fuel to convert a pound of water into steam at a higher than at a lower temperature and pressure. In reality, however, the difference is very slight. Referring back to the table it will be seen that it requires 1146·6 units of heat to raise a pound of water from 32° to 212°, and evaporate it at that temperature; of these 180 are expended in raising the temperature, while 1146·6 – 180, or 966·6 units, become latent in the steam. It only requires 1171·2 units, however (261 sensible and 910·2 latent), to raise the water to 293°, and evaporate it at that temperature; for the latent heat falls nearly as fast as the sensible heat rises. The additional heat required is thus only a little over 2 per cent., while the pressure—which is, *cæteris paribus*, a measure of the work the steam will do—is more than quadrupled. In this way a large increase of power in any engine may be obtained by a small additional expenditure of fuel, and consequently steam of a high pressure is now being used for all purposes, its economy and advantages being fully recognised by engineers. It was thought for a long time that the *total* heat of steam—i.e. the sum of the sensible and latent heats—was constant at all temperatures; but this is not strictly the case, although the table shows that the difference for ordinary ranges of pressure is but trifling. See HEAT, and GAS.

Steam-carriage. See TRACTION-ENGINE.

Steam-crane. See CRANE.

Steam-digger. The successful application of steam to the 'digging' of the soil can hardly be said to date further back than 1880. In that year at the Royal English Show at Carlisle Messrs M'Laren of Leeds exhibited the Darby Digger, for which they received the society's special silver medal. This digger was the invention of Mr T. C. Darby of Pleshey Lodge, Chelmsford, a gentleman-farmer, who expended large sums of money and much anxious labour upon the perfecting of this most useful implement. The problem of steam-digging was now successfully solved, and it is surprising that the system has not been more largely adopted. The action of the digger in the soil is quite different from that of the plough. It is much more beneficial to the soil from almost all points of view. Not only is there a saving in power, but the quality of the work done is far superior to that accomplished by the plough. The steam-digger indeed imitates closely digging by hand, and hand-digging is the most perfect of all methods of tillage. By the process of digging the soil is much more thoroughly pulverised than by ploughing. The digging-forks of the steam-digger tear up the soil and toss it over in forkfuls in a manner which leaves both the subsoil and surface-soil more open than is the case in ploughing. The action of the plough in cutting the furrow from the subsoil tends to the formation of a 'pan' on the top of the subsoil. The digger 'tears' instead of 'cuts' the surface-soil from the subsoil, and this tearing action tends to loosen the latter. Most farmers who have tried both steam-ploughing and steam-digging much prefer the latter, not only because they believe that from digging the crops are better and the weeds fewer, but also because the digging appliances are much more simple, and involve less cost for tear and wear, and for attention in working, than the steam-ploughing gear. The curious circumstance that fewer weeds grow up on land turned over by the steam-digger than on ploughed land is attributed to the fact that, while the digging-forks tear deep-rooted weeds out of the subsoil and toss them on the surface, where they are killed by exposure, the plough merely cuts the long roots in two, leaving one portion to send forth a new crop of weeds. The Darby digger consists of a steam-engine with working parts similar to those of an ordinary traction-engine fixed on the top of a double locomotive boiler. The power is communicated by steel spur gearing to a long horizontal shaft running parallel with the centre line of the boiler. Thence it is transmitted to the digging-cranks by wheels and pinions of cast steel. There are six digging forks, each about 42 inches wide, so that the digger turns over a breadth of about 21 feet at a time. The digging-forks can be set to work at various depths, down to about 14 inches. Whilst digging the digger travels sideways, and has thus been designated the 'broadside' digger. For travelling on the road the travelling wheels can be turned so that it moves like an ordinary traction-engine. When digging it travels at the rate of about half a mile per hour, and allowing for turning and stoppages digs over an acre per hour. The cost of this digger with an 8 horse-power engine is £1200, and its inventor claims that it will dig ten acres per day at a net cost of nine shillings per acre, including men's wages, coal, interest on capital and depreciation. The digger invented by Mr Frank Proctor, of Stevenage, consists of an ordinary traction-engine geared into a crank shaft, which works three forks in the rear, so that as the engine travels forward in the usual manner the ground is left dug up behind. These forks can be thrown out of gear or hinged up to permit of the engine being used for threshing or other purposes. This system is comparatively cheap, simple, and effective. An 8 horse-power digger costs £800, and in a day of ten hours should dig ten acres, consuming about 11 cwt. of coal, and requiring the attendance of two men.

Steam-engine. Steam-engines in their infancy were known as 'fire' (i.e. *heat*) engines; and in point of fact the older term is the more correct, because the water or steam is only used as a convenient medium through which the form of energy which we call heat is made to perform the required mechanical operations. In modern engines sufficient heat is added to the steam to raise it to a very high pressure, and the excess of this pressure over the pressure opposed to it (either atmospheric pressure or the still lower pressure in a condenser) is both the cause and measure of the work done by the engine. In earlier machines, however, the steam was raised only to atmospheric pressure, and admitted into the engine only to be at once condensed by a jet of cold water. The excess of the atmospheric pressure above the pressure in the partial vacuum caused by the condensation was then the direct cause of work. Engines of this kind were called *atmospheric* engines.

The invention of steam as a moving power is claimed by various nations; but the first extensive employment of it, and most of the improvements made upon the steam-engine, the world indisputably owes to Britain and the United States.

Among the first notices we have in England of the idea of employing steam as a propelling force, is in *The Art of Gunnery* (1647), by Nat. Nye, mathematician; in which he proposes to 'charge a piece of ordnance without gunpowder,' by putting water instead of powder, ramming down an air-tight plug of wood, and then the shot, and applying a fire to the breach 'till it burst out suddenly.' But the first successful effort was that of the Marquis of Worcester. In his *Century of Inventions*, the manuscript of which dates from 1655, he describes a steam-apparatus by which he raised a column of water to the height of 40 feet. This, under the name of 'Fire-waterwork,' appears actually to have been at work at Vauxhall in 1656. Sir Samuel Morland in 1683 submitted to Louis XIV. a project for raising water by means of steam, accompanying it with ingenious calculations and tables. The first patent for the application of steam-power to various kinds of machines was taken out in 1698 by Captain Savery. In 1699 he exhibited before the Royal Society a working model of his invention. His engines were the first used to any extent in industrial operations; they seem to have been employed for some years in the drainage of mines in Cornwall and Devonshire. The essential improvement in them over the older ones was the use of a boiler separate from the vessel in which the steam did its work; one vessel in all former engines had served both purposes. He made use of the condensation of steam in a close vessel to produce a vacuum, and thus raise the water to a certain height, after which the elasticity of steam pressing upon its surface was made to raise it still further in a second vessel.

In all the attempts at pumping-engines hitherto made, including Savery's, the steam acted directly upon the water to be moved without any intervening part. To Denis Papin (q.v.), a French physicist, is due the idea of the *piston*. It was first used by him in a model constructed in 1690, where the cylinder was still made to do duty also as a boiler; but in an improved steam-pump invented about 1700 he used it as a diaphragm floating on the top of the water in a separate vessel, or cylinder, and the steam, by pressing on the top of it, forced the water out of the cylinder at the other end.

The next great step in advance was made about 1705 in the 'atmospheric' engine, conjointly invented by Newcomen (q.v.), Cawley, and Savery. This machine (fig. 1) held its own for nearly seventy years, and was very largely applied to mines. In it the previous inventions of the separate boiler and of the cylinder with its movable steam-tight piston are utilised, although in a new form. The 'beam,' which has ever since been used in pumping-engines, was used for the first time, and

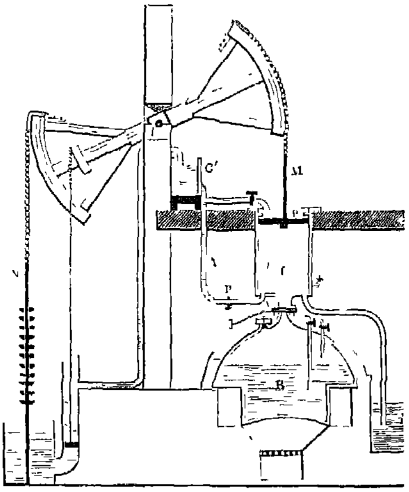


Fig. 1.

for the first time also the condensation of the steam was made an instantaneous process, instead of a slow and gradual one. *Newcomen's engine* was chiefly used, like all former steam-engines, in raising water. To one end of a beam moving on an axis, I, was attached the rod, N, of the pump to be worked; to the other the rod, M, of a piston, P, moving in a cylinder, C, below. The cylinder was placed over a boiler, B, and was connected with it by a pipe provided with a stopcock, V, to cut off or admit the steam. Suppose the pump-rod depressed, and the piston raised to the top of the cylinder—which was effected by weights suspended at the pump-end of the beam—the steam-cock was then turned to cut off the steam, and a dash of cold water was thrown into the cylinder by turning a cock, R, on a water-pipe, A, connected with a cistern, C'. This condensed the steam in the cylinder, and caused a vacuum below the piston, which was then forced down by the pressure of the atmosphere, bringing with it the end of the beam to which it was attached, and raising the other along with the pump-rod. The cock was then turned to admit fresh steam below the piston, which was raised by the counterpoise; and thus the motion began anew. The opening and shutting of the cocks was at first performed by an attendant, but subsequently a boy named Humphrey Potter (to save, it is said, the trouble of personal superintendence) devised a system of strings and levers by which the engine was made to work its own valves. In 1717 Henry Beighton, an F.R.S., invented a simpler and more scientific system of 'hand-gear,' which rendered the engine completely *self-acting*. During the latter part of the time that elapsed before Watt's discoveries changed everything Smeaton brought Newcomen's engine to a very high degree of perfection. As the result of study and experiment he made many improvements in it, in the form of the boiler, the proportions of the cylinder, &c. It was he, too, who invented the *cataract*, a very ingenious *self-acting valve arrangement*, which is still used in Cornish engines. In 1725 Leupold invented an engine in which steam of a higher pressure than that of the atmosphere was employed in the cylinder, but his engine possessed defects that prevented its practical use.

The next essential improvements on the steam-engine were those of Watt, which began a new era in the history of steam-power. The first and most important improvement made by Watt was the separate condenser, patented in 1769. He had observed that the jet of cold water thrown into the cylinder to condense the steam necessarily reduced the temperature of the cylinder so much that a great deal of the steam flowing in at each upward stroke of the piston was condensed before the cylinder got back the heat abstracted from it by the spurt of cold water used for condensing the steam in the cylinder. The loss of steam arising from this was so great that only about one-fourth of what was admitted into the cylinder was actually available as motive-power. Watt therefore provided a separate vessel in which to condense the steam, and which could be kept constantly in a state of vacuum, without the loss which arose when the cylinder itself was used as a condenser. This device, which now looks simple enough, was the greatest of Watt's inventions, and forms the foundation of his fame. His genius was such that in a few years he changed the steam-engine from a clumsy, wasteful, almost impracticable machine into a machine practically the same as that which we now have. The principal improvements since his time have been either in matters relating to the boiler; in details of construction consequent on our increased facilities, improving machinery, and greater knowledge of the strength of materials; in the enlarged application of his principle of expansive working; or in the application of the *steam-engine to the propulsion of carriages and vessels*. His principal inventions were: (1) The condensation of steam in a vessel separate from the cylinder, so as to avoid the cooling of the latter; (2) the use of a pump, called an 'air-pump,' to withdraw the condensed water and mixed steam and air from the condenser; (3) the *surrounding of the cylinder with a steam-jacket*, in order to prevent loss of heat from condensation (these three, with others, were included in the specification of 1769); (4) the use of the steam expansively in the way explained further on in this article (this was invented before 1769, but not published till 1782); and (5) the now universally used double-acting engine, and the conversion of the reciprocating motion of the beam into a rotary motion by means of a crank (both these were invented before 1778, the engine being patented in 1782, but the crank having before that date been pirated and patented by another). In 1784 Watt also patented and published his parallel motion, throttle-valve, governor, and indicator; all four of which are in substance still used.

The common mode of employing steam in an engine is by causing it to press alternately on the two surfaces of a movable diaphragm or piston enclosed in a fixed, steam-tight, cylindrical box. In fig. 2 A is the piston and B a section of the box. The piston, by means of a rod, E, passing through the end of the box, is made to communicate motion to the rest of the machinery. The steam is first admitted to one end of the cylinder through an opening or 'port,' D, and forces the piston along to the other end. The current of steam from the boiler is then allowed to pass into the other end of the cylinder through the opening C, and forces the piston back again to its original position, and so on. But it is obvious that while this return-motion is going on the steam previously admitted at D must be allowed some exit, or the piston could not be forced back. The manner of this exit constitutes the difference between the two principal classes of engines, according as the steam is allowed simply to rush out into the atmosphere or is conducted into a separate vessel, and there 'condensed.'

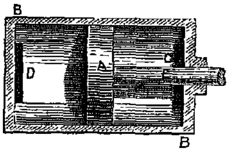

Fig. 2.

The simplest way in which steam can be used in a cylinder is at the same time the most wasteful. It consists in filling each end of the cylinder alternately full of steam direct from the boiler, and having the full boiler pressure, and thus forcing the piston along in exactly the same way as that in which it would have to be forced were water the fluid used instead of steam. If we imagine the cylinder to have a capacity of 7 cubic feet, then, if it be filled entirely with steam from the boiler at 60 lb. absolute pressure, it will contain (about) one pound-weight of steam. The total heat in this pound of steam (above 32° F.), as given in the table, is equivalent to 1171 thermal units in excess of that possessed by a pound of water at 32° F. When the piston, A, has reached the end of its stroke, the steam contained in the cylinder is thus in itself a great storehouse of work, for each of these thermal units is equivalent to 772 'foot-pounds' of mechanical energy, so that the total represents about 904,000 foot-pounds, of which we shall see later on only about $\frac{1}{20}$ has been utilised during the stroke, leaving $\frac{19}{20}$ untouched. Instead of making any attempt to utilise this huge balance, at the moment when the cylinder is full of steam the opening C is put into communication with the boiler, the opening D with the atmosphere, and the steam immediately rushes out of the cylinder, and dissipates its contained energy through the air. Although the steam, when allowed to go into the atmosphere, is immediately reduced to the pressure corresponding to the temperature of the air (which in ordinary cases would be only a fraction of a pound per square inch), still the full pressure of the atmosphere itself will always be acting on the back of the piston during its stroke, and therefore, to find the force with which the piston is being pushed along, we must subtract that pressure from the steam pressure. On the one side of the piston will be the atmosphere with its uniform pressure of nearly 15 lb. per square inch, and on the other side the steam-pressure of 60 lb. The effective pressure thus will be 60 – 15, or 45 lb. per square inch only.

Let us now consider the somewhat more economical case of an engine in which the steam is first used as described above, but afterwards, instead of being allowed to pass into the atmosphere, is conducted through a pipe into a closed vessel and there condensed. Condensation consists in the subtraction from steam of a portion of its sensible heat. This reduction of temperature has a double effect on the steam: (1) the cooling and liquefaction of a part of it; and (2) the reduction of the rest to the pressure corresponding to the reduced temperature. It is not possible to do one of these things without the other. What is commonly called 'vacuum' simply means pressure less than the atmospheric pressure; and, in the case of steam-engines, a vacuum generally implies a pressure of between 2 and 3 lb. per square inch—i.e. from a seventh to a fifth of the ordinary pressure of the air. The most common way of condensing steam is by bringing it into contact either with a jet of cold water or with surfaces kept continually cool by a current of water. In either case, directly the steam is brought into contact with the water or cooling surface, it transfers to it the larger portion of its sensible heat. During this process the greater part of the steam is liquefied, and the remainder retains only such a pressure as corresponds to its greatly reduced temperature.

The advantages possessed by a condensing over a non-condensing engine will now be obvious. When the piston is being forced from C to D by steam entering through C, the force on the back of the piston resisting its motion in that direction, *instead of being equal to the pressure of the atmosphere*, is only the pressure of the steam in the condenser, or about 2 lb. per square inch. The net effective force is therefore 60 – 2 or 58 lb. instead of 60 – 15 or 45 lb.

We have supposed that our cylinder when full of steam contained just one pound-weight at 60 lb. pressure. Let us now find out how much useful work this pound of steam has done for us, and we will then show how the same weight may be made to do a great deal more, by utilising more of its great store of heat. Let us suppose that the area of the cylinder is 2 square feet, while its length (the stroke of the piston) is 3½ feet. It will thus have a capacity of 7 cubic feet, as before assumed. In the first case described we should have a pressure of 45 lb. per square inch exerted on an area of 288 square inches through a distance of 3½ feet. This is equal to 45,360 foot-pounds of work. In the second case we have a pressure of 58 lb. per square inch on the same area and through the same distance. This is equal to 58,464 foot-pounds of work, or about $\frac{1}{16}$ of the total heat supplied by the fuel. (For simplicity's sake we have here assumed that the water in the boiler has to be raised from 32° to 292°, and evaporated at that temperature. If the water were supplied at 212°, then the work done would be about $\frac{1}{13}$ instead of $\frac{1}{13}$ of the total heat.) We may now proceed to examine the way in which the same weight of steam, generated by the consumption of an identical weight of fuel, may be made to perform many times more work by 'working expansively.'

One of the properties possessed by steam, in common with all other gases, is a tendency to expand indefinitely, its pressure varies nearly inversely as its volume. For simplicity's sake we shall here assume that steam is a perfect gas, and follows Boyle's law, the pressure varying *exactly* inversely as the volume. If then we have a cylinder of the same area as before, but of twice the length, but only intend to admit 1 lb. of steam into it at a time, it will be necessary, when the piston has travelled 3½ feet of its stroke, to shut the entrance valve, so as to prevent more steam entering; this is called 'cutting off' the steam. The piston, however, still continues its motion in the same direction as before, propelled by the internal separative energy among the particles of steam. But as it is pressed forward the space occupied by the steam is always increasing, and its pressure always decreasing in proportion, until at length, when the piston has reached the end of its stroke, the steam occupies exactly double its original volume—viz. 14 cubic feet, and is reduced in pressure to half its original pressure—viz. to 30 lb. per square inch. We have thus during the first half of the stroke a constant pressure on the piston of 60 lb. per square inch, and during the second half a pressure gradually decreasing from 60 to 30 lb. The *mean* pressure during this second half of the stroke will be found on calculation to be almost exactly 40 lb. Let us now, in the same way as before, see what work we have been able to get out of our pound of steam by expanding it in this way. In the first half of the stroke we have 58,464 foot-pounds of work exactly as before, and then we have in addition a mean pressure of 40 – 2, or 38 lb. per square inch, exerted over 288 square inches for a distance of 3½ feet. This equals 38,304 foot-pounds, making a total of 96,768 foot-pounds of work obtained from the steam which only gave us 58,464 before. The economy of working expansively, however, goes much further than this. If the cylinder had been four times its original length, and the steam had been cut off at the same point as before (which would then be quarter instead of half stroke), we should have obtained from the 1 lb. of steam about 144,000 foot-pounds of work. If we had gone still further and expanded the pound of steam into eight times its original volume, we should have obtained about 180,000 foot-pounds of work, which is more than three times as much as at first. (In actual working, owing to various causes—such as imperfect action of the valves, radiation from the cylinder, bad vacuum, &c.—the work obtained from the steam is not more than ·65 to ·75 of that given in this paragraph.) All modern engines are worked more or less on this principle of expansion, and the general tendency seems to be every year to adopt higher initial pressures and (within certain limits) larger ratios of expansion.

Fig. 3 represents Watt's 'double-acting' condensing engine. By 'double-acting engine' we mean an engine such as was sketched in fig. 2, in which the steam acts on both sides of the piston instead of only on one, as in Newcomen's engine. Watt's engine, though not of the form now generally used, contains all the parts now considered essential. The steam from the boiler passes direct to the valve-chest, *v*, which is simply a long box attached to the cylinder, *a*. In this chest are placed valves, which are so regulated as to open communication between the boiler, cylinder, and condenser, in such a way that when the top of the cylinder is open to the boiler the bottom communicates with the condenser, and *vice versâ*. When the steam has done its work it passes out through the bent pipe into the condenser, *f*, where it is met by a jet of water (not shown in the engraving), and condensed, as before explained; *g* is a pump called the air-pump, which continually draws away the contents of the condenser, and discharges them into a cistern, *h*, called the hot well. A small force-pump, *j*, draws part of the water from this cistern, and sends it back again to the boiler, there to be reconverted into steam, while the rest of the water is allowed to run to waste. A suction-pump, *k*, supplies water to the large tank round the condenser, and also for the condensing jet. Inside the cylinder are the piston and the rod (called the piston-rod) connecting it with the beam, *bb*. In Newcomen's engine the rod had only to pull the beam down, and not to push it up; it could, therefore, be connected to it by a chain, as shown in fig. 1. In the double-acting engine the piston-rod is required both to pull and to push the beam, so that the chain is no longer admissible. It is obvious that as the head of the rod must move in a straight line, while every point in the beam describes an arc of a circle, the two cannot be rigidly connected. Watt invented the arrangement of rods shown in fig. 3, by which the piston-rod head is always guided in a straight line, while the end of the beam is left free to pursue its own course. This is called a 'parallel motion.' The end of the beam farthest from the cylinder is connected by a rod, *cc*, called a connecting-rod, to the crank, *l*, which is firmly fixed on the shaft; and by this means the reciprocating motion of the beam is converted into the rotary motion of the 'crank-shaft,' *r*. The governor, *m*, and the flywheel, *ee*, will be explained further on.

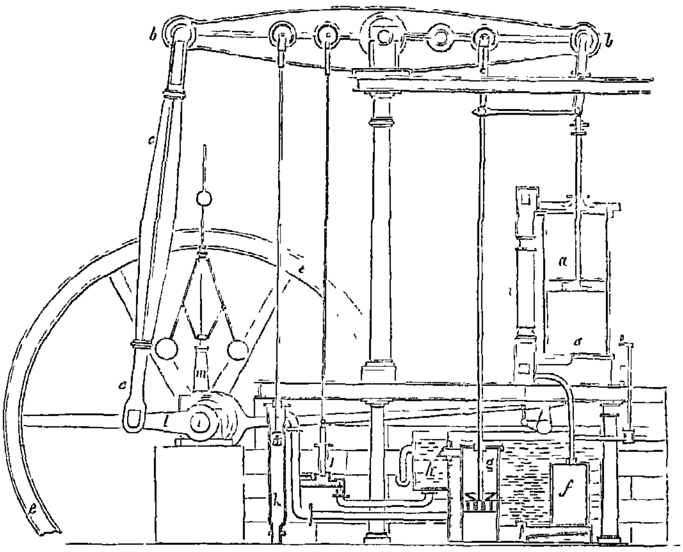

Fig. 3.

The *cylinder* and its *piston* are both made of cast-iron. The former is very accurately bored in a special machine, and ought always to be covered outside with non-conducting material to prevent radiation of heat. It is frequently enclosed in another cylinder, and the annular space or 'jacket' between them filled with steam from the boiler, principally with the object of preventing liquefaction in the cylinder, which is fatal to economical working. The openings for the entrance and discharge of the steam (shown at C and D in fig. 2) are both called *ports*.

The *valve* or valves which regulate the admission of steam to the cylinder vary very much in construction and design. In ordinary engines one valve, called a *slide-valve*, does the whole work for each cylinder in a way which we shall explain by the aid of fig. 4. This figure shows the valve in two positions—viz. those corresponding to the times when the piston is at the middle of its stroke, going in the two different directions; *c* and *d* are the ports, the ends of which are denoted by the same letters in fig. 2; *b* is the 'exhaust port,' or opening through which the steam passes to the condenser; and *a* is the slide-valve working inside the steam-chest (the latter not shown). The sketch to the left shows the position of the valve when the piston is moving upwards. The steam enters the cylinder through *d*, as shown by the arrows, while the steam in the other end is free to rush out by *c* under the valve, and through *b* into the condenser. By the time the piston has reached the same position, going in the opposite direction, the valve is in the position shown in the right-hand sketch, and the motion of the steam is exactly reversed. The valve in fig. 4 opens one port at the same moment as it closes the other. This corresponds to entirely non expansion working. In order to 'cut off' the steam before the end of the stroke the breadth of the ends of the valve must be increased. This is called *giving 'lap'* to the valve. When it is desired to 'cut off' the steam earlier than half-stroke, a separate valve, called an *expansion valve* (of which there are innumerable varieties), is generally used. The rod to which the piston is attached is called the *piston-rod*, and the rod which actually drives the crank the *connecting-rod*. In Watt's engine and similar machines these are connected to opposite ends of a *beam*, but in the common type of engine shown in fig. 6 (below) the two rods are directly attached. The *flywheel* is a large wheel fixed on the crank-shaft, and having a very heavy rim. As it revolves this contains, *stored up* in itself, a great quantity of energy, and so equalises the motion of the shaft, and by *restoring* some of the energy enables the engine to pass the 'dead-points,' or points at which the connecting-rod and crank are in a line. The *condenser* is simply a cast-iron box of any convenient shape.

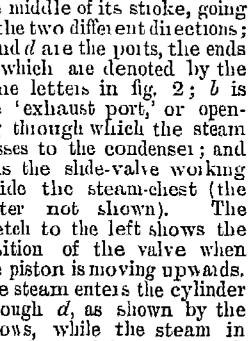

Fig. 4.

The water for condensing the steam is introduced into it in a jet in such a way that its particles mix with the steam at once on entering, and condense it almost instantaneously.

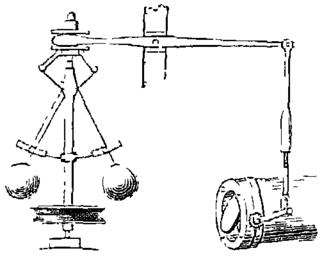

Fig 5.

The *governor*, shown in fig. 5, is an ingenious application by Watt of mechanism long used in water-mills. Its object is to make the engine to a great extent regulate its own speed, so that it shall neither be pulled up altogether by a sudden increase of load, nor 'race' when any part of its load is suddenly removed. It consists essentially of a spindle or upright rod, with a pulley by which it is caused to revolve fixed on it. Two levers are pivoted on a pin near the top of the spindle, and at the lower end of each is fixed a heavy cast-iron ball. When the engine is running at its proper speed the balls revolve with the spindle in the position shown; but if that speed be increased the centrifugal force causes them to fly outward, and consequently upward; and conversely, if it be decreased they fall downward towards the centre. At the upper end of the spindle is a system of levers, by which it will be seen that the raising of the balls tends to close, and their lowering to open, the *throttle-valve* at the right of the engraving. The valve in the figure is simply a disc of metal placed in the steam-pipe near the cylinder, but a great many other types of valve—more expensive but more efficient—are now used for the same purpose. The further this valve is opened the greater the amount of steam admitted to the cylinder, and *vice versâ*, and so the tendency of the engine to alter its speed arising from causes extraneous to itself is just balanced by the alteration made in the amount of steam admitted through the throttle-valve. In order that economy as well as regularity of working may be attained, it is in many cases necessary that the governor should be so arranged as to control the 'cut-off' instead of throttling the steam as in the figure.

The 'Cornish' engine, so called from the fact that it is principally used in the Cornish mines, resembles Watt's engine in general appearance. Like Newcomen's engine it is used exclusively for pumping and has no rotary motion, and it is virtually single-acting; but, unlike his, the steam-pressure and not that of the atmosphere actually does the work. Cornish engines are fairly economical of steam, but are very costly and extremely heavy and unwieldy.

Engines in which the piston-rod and connecting-rod are directly attached are called *direct-acting engines*, of which the horizontal engine shown in fig. 6 is the most common type. For all ordinary purposes direct-acting engines are rapidly superseding every other form. They possess the merit of having great simplicity and few working parts, and of all these parts being easily accessible to the engine-driver; and at the same time any required degree of economical working can be obtained in them as well as in any other form. They were at first only used as non-condensing (or so-called 'high-pressure') engines, but are now as frequently made with a condenser attached.

Two other forms of direct-acting engines have been much used in their day, but are now being rapidly abandoned except under special circumstances; these are called respectively the '*oscillating*' and the '*trunk*' engine. In the former (which has rarely been used except for marine engines) the crank-shaft is above the cylinder, the piston-rod head is attached to the crank-pin, and the connecting-rod is dispensed with by allowing the cylinder to oscillate on large hollow centres called *trunnions*, and so to adapt itself to the various positions of the crank-pin. In the 'trunk' engine the piston-rod becomes a hollow cylinder or *trunk*, large enough to allow the connecting-rod to vibrate inside it. The latter is then attached at one end to the crank-pin as usual, and at the other to a pin fixed in the piston.

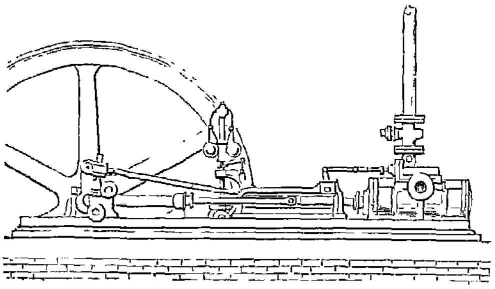

Fig. 6.

Direct-acting engines are now made to run at extremely high speeds, for driving dynamos, &c. direct. For this purpose they are made single-acting only, so that the steam-pressure tends always to keep the working surfaces pressed together, and there is none of the shock and noise found in ordinary engines where the direction of pressure is reversed at each stroke. The first successful machine of this type was Mr Brotherhood's 'three-cylinder' engine, of which an immense number are in use. Of late years Mr Willans, in his 'central valve' engine, has added an exceptional degree of economy in steam to the other advantages of the single-acting type. Willans' engines are now very commonly used in the more important electric lighting stations in Britain for the direct driving of dynamos, and have given most satisfactory results. An immense amount of ingenuity has been expended in devising engines in which the rotary motion of the shaft is obtained *directly* from the piston without the intervention of reciprocating parts. These machines are called *rotary* engines; they have never come into general use, and most of them have been defective in construction as well as founded on a dynamical misconception.

In *locomotive engines* it is necessary that the whole machinery should be compressed into the smallest possible bulk, and this necessity is the cause of their principal peculiarities. The engine itself is much the same as an ordinary horizontal engine, and has two cylinders placed side by side near the front of the locomotive. These cylinders are sometimes placed inside the main framing, which runs the whole length of the engine, and sometimes outside it, each plan having certain advantages. Fig. 7 is an outline section of an 'inside cylinder' goods-locomotive belonging to the Midland Railway Company. At the back of the locomotive is the firebox, *a*, the bottom of which is formed by the grate, *b*. Fuel is introduced by the door, *c*. The firebox is enclosed in a casing, *d*, and the space between is filled with water. This space communicates freely with the barrel, *e*, *e*, of the boiler, a long wrought-iron or steel cylinder. From the back of the firebox numerous small tubes traverse the boiler (through the water) to the smoke-box, *f*, and conduct the products of combustion to the chimney, *g*. The steam-pipe, *k*, is led away from near the top of the dome, *h*, and fitted with a regulator valve, *l*. At *m* are a pair of spring safety-valves. Both cylinders discharge their steam through the vertical blast-pipe, *p*, and by this means a sufficient draught is caused, notwithstanding the small height of the chimney. The cylinders, *r*, are placed in the bottom of the smoke-box, and partly enclosed in it.

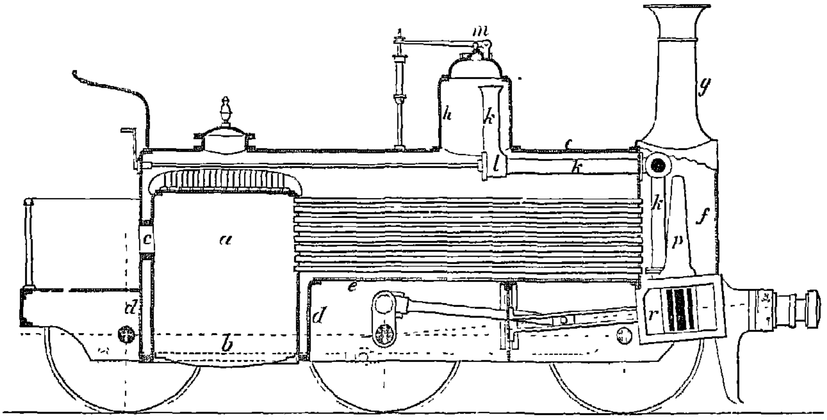

Fig. 7.

In all *marine engines*, except the very smallest, two cylinders are used, working cranks at right angles to each other, so as to equalise the motion as far as possible, it being almost impossible to use a flywheel of sufficient weight for that purpose on board ship. The form originally known as the 'steam-hammer' engine (from the resemblance of early models to Nasmyth's steam-hammer), or some modification of it, is now almost universally adopted. They are direct acting, but the cylinders are inverted, and placed right above the propeller shaft. Two of the greatest improvements in the modern steam-engine—the *surface-condenser* and the *compound engine*—have been brought to perfection chiefly in connection with marine engines here. In the surface-condenser the steam is condensed by contact with the exterior surface of a great number of small tubes, through the interior of which a current of cold sea-water is kept constantly flowing. By this means the condensing water and the condensed steam are kept separate, the former being returned to the sea, and the latter only sent into the hot well. The boiler, therefore, is continually fed with distilled water, and the wasteful process of 'blowing off,' to get rid of the unvaporisable matter which would otherwise be deposited in the boiler, is rendered unnecessary.

In 'compound' engines the two cylinders are of unequal size—the larger, called the low-pressure cylinder, having from three to four times the capacity of the smaller or high-pressure cylinder. The steam from the boiler is admitted into the latter in the usual way, and cut off generally at from ⅜ to ⅝ of the stroke; and after doing its work there, it is conducted to the large cylinder, where its reduced pressure, by acting on an increased area, does as much work as in the other cylinder, and thence to the condenser. This system of engine has several notable advantages—among which are that the driving pressures are more uniform than in ordinary engines; that leakage past the piston becomes of less importance; that for any given *large* measure of expansion the mechanism of the engine is much more simple than for the same degree of expansion carried out independently in two cylinders; and that the losses due to condensation of steam in the cylinders (which are now known to be among the most serious of all causes of waste) are much reduced.

In modern marine engines, and to some extent also in mill engines, the compound principle is now carried further, and 'triple expansion' engines (which are simply compound engines with three cylinders used consecutively instead of two) are very widely employed, with very economical results. In these engines steam is not uncommonly used at a pressure as great as 150 lb. per square inch, or six times as much as was usual about 1860. Quadruple engines are also used.

The Work done by Steam-engines is estimated in two ways—as *horse-power* and as *duty*, and the first expression includes two things—nominal and indicated horse-power. Thirty-three thousand foot-pounds of work done per minute is called one horse-power, this being considered by Watt as the maximum rate at which a strong horse can work. The *nominal* horse-power of an engine has long ceased to be any expression of the actual power it exerts; it is only used as a kind of commercial standard (a very deficient one) for the sale and purchase of engines, and is generally made to depend entirely on the diameter of the cylinder. The *indicated* horse-power is the most useful measure we have of the work done by an engine. It expresses, however, not the work itself, but the rate at which that work is being done in the cylinder. It has to be remembered also that it does not show at all what proportion of that work has to be expended in overcoming the friction of the engine itself. It is ascertained by the use of a little machine called an 'indicator,' devised by Watt, and since his time greatly improved, especially by Richards and by the Crosby Company. By taking the *mean* pressure per square inch on the piston throughout the stroke (measured from the indicator diagram), and multiplying it by the area of the piston and by the number of feet passed through by it in a minute, we can find the number of foot-pounds of work done by the engine per minute; and this, divided by 33,000, gives the indicated horse-power.

'Duty' is an expression used only for pumping-engines, and differs from horse-power in being entirely independent of time—i.e. it is a measure of work done, and not of the rate at which it is done. It is the number of foot-pounds of nett work resulting from the consumption of a given quantity of coal, usually either a bushel of 94 lb. or a cwt. At the beginning of the 19th century the maximum duty that had been attained by any Cornish engine was 20 millions of foot-pounds per cwt. of coal, but six times that duty has since been occasionally obtained. In these engines it is the actual nett work done which is taken into account; the duty would be 20 or 25 per cent. greater if the total load on the steam-piston had been considered instead.

For engines whose power can only be measured by the indicator the standard of economy is the number of pounds of steam used per hour per indicated horse-power. A first-class non-condensing engine, working with steam of about 100 lb. pressure, uses about 22 lb. of steam per i.h.p. per hour, which is reduced to 17 or 18 lb. by the employment of condensation. Occasionally better results than these are obtained, but in ordinary good work the figures are at least 25 per cent. greater, and they are often more than double as great. In any case economy is only to be obtained if the engines are worked at or near their full power, and with the full steam-pressure for which they are intended. It is very common to speak of the amount of coal burned per i.h.p. per hour, and this is a very important quantity. It is, however, a measure of the combined economy of a boiler and engine, and not of the economy of an engine alone. A pound of Welsh coal can be made to evaporate 10 to 11 lb. of water under special conditions. In ordinary circumstances and over long periods the evaporation is more like 7½ to 9 lb. of water per lb. coal. Inferior fuels, or even good fuel badly burned, give, of course, very much lower results.

L. Galloway's *The Steam Engine and its Inventors* (1881), Thurston's *Steam Engine* (Inter. Sc. Series).

Steam-hammer, a contrivance which has done more perhaps than any other mechanical invention of modern times to develop the wonderful resources of the iron trade. The first idea of a steam-hammer appears to have been due to James Watt, the great father of engineers, and was patented by him in 1784. In 1806 William Deverell, 'an engineer of Surrey,' also took out a patent for one; but in neither case does it appear that steam-hammers were actually constructed, though in both specifications a direct-acting steam-hammer is, so to speak, sketched in words. From this time till 1839 the idea seems to have been entirely lost sight of. It was then again taken up by Mr James Nasmyth, of the Bridgewater Foundry near Manchester. Mr Humphries, engineer to the Great Western Steamship Co., who had been unable to induce any forge-master to undertake the heavy forgings required for the intermediate paddle-shafts of the *Great Britain* steamship, then in course of construction, applied to his friend Nasmyth for suggestions as to how this difficulty might be overcome. Nasmyth made a sketch of a hammer operated by steam-power, and sent his sketch to Humphries, who, along with Brunel and others, heartily approved of the scheme; but in consequence of a change of design, and the substitution of a screw for paddles, the proposed heavy shafts were not required, and the hammer was not then constructed. The scheme was then offered to many forge-masters and engineers; but they failed to duly appreciate its value and importance, and the hammer remained a mere sketch in Nasmyth's 'scheme-book' till 1842. In the spring of that year Nasmyth, much to his surprise, saw at Creusot in France a steam-hammer at work, which had been built in accordance with a copy of his own rough 'scheme-book' sketch, made by two French engineers during a business visit to the Bridgewater works. Nasmyth had been previously urged by his friends to protect his invention by a patent, and immediately on his return to England secured one in June 1842. It is interesting to note that this patent mentions the use of steam above the piston to increase the intensity of the blow, and also a self-acting arrangement. The first English steam-hammer under this patent was made at the Bridgewater Foundry early in 1843; but, although considered an improvement upon the old 'helves' hitherto used for forging purposes (see HAMMER), it was far from being a perfect tool. The principle on which the hammer worked was as follows: two vertical columns or frames supported an inverted vertical steam-cylinder; the hammerhead or tup was attached to the rod of the piston working in this, while vertically beneath, supported on the floor, was the anvil; steam admitted beneath the piston raised it, and with it the hammerhead, at some chosen point the supply was cut off and the steam beneath the piston allowed to escape into the atmosphere, the piston and tup at once fell and gave a blow to anything placed on the anvil; the force of this blow simply depended on the weight of the tup and the height to which it was raised before being allowed to fall. The admission and exhaust of the steam was controlled by means of an ordinary slide-valve worked by a long lever, requiring great labour and constant attention in order to give the blow required; some automatic contrivance was considered necessary to secure complete command over the power of the blow, and to insure that the instant the blow was struck the block should immediately rise again, thus preventing the heat in the mass of iron on the anvil being reduced by the cold face of the block. The peculiar difficulty of securing a true automatic arrangement will be seen, when it is considered that the time of descent of the hammer must vary with almost every blow that is struck; for the piece on the anvil becomes thinner and thinner by each succeeding blow, and with flat bars a blow is first given on the flat side and then on the edge, the difference in the fall of the hammer in the two cases being often many inches; furthermore the hammer must be under perfect control at all times.

It is stated that Nasmyth failed to devise a satisfactory automatic arrangement, but Mr Robert Wilson, then engineering manager of the works, afterwards managing director and successor to Nasmyth on his retirement, who was assisting to work out the details, after a week's scheming solved the difficult problem. His automatic device was first tried on a small 5-cwt. hammer, the second one made, and as it at once proved successful was immediately fitted to several 5-ton hammers then under order; the first one actually made for sale was delivered to the Low Moor Ironworks on August 18, 1843, and answered every expectation. This improvement was covered by a patent taken out by Nasmyth in July 1843. The time of releasing steam from under the piston, and therefore the height of fall, was regulated by a tappet-lever carried by two vertical screws. The tup in its upward movement struck this lever, thereby moving the valve, cutting off the steam, and also releasing it so as to allow the hammerhead to fall. The attendant turning these screws by a small hand-wheel was able to rapidly alter the vertical height of the tappet-lever, and therefore the length of fall. The second point—i.e. the instant rise of the tup after the blow—was obtained in a very ingenious fashion by taking advantage of the inertia of a rocking lever carried on the tup. When the hammerhead struck the metal on the anvil, this lever, by virtue of its momentum, continued to move down against the resistance of a light spring, and in doing so set in motion a system of levers which at once opened the valve, admitted steam under the piston, and again raised the tup. The system of levers could also be operated by hand; thus steam could be admitted under the piston, and the hammer checked and stopped at any point of its descent. This gearing reduced enormously the labour of operating the hammer, increased greatly the number of blows which could be given in any time, and brought it so completely under control that while at one instant the tup could be brought down so gently that it failed to crack an egg on the anvil, the next blow could be made to shake the very ground on which the hammer stood with the violence of the shock. Such satisfaction was given by this remarkable tool that orders began at once to flow in from all parts of the country. The hammer remained in this condition, with slight improvements in details, till 1853, when Wilson devised and applied to steam-hammers what is known as the 'circular balanced valve,' in substitution for the flat slide-valve hitherto used. The steam-pressure on the back of the old flat valve was so great that the friction during any movement of the valve was excessive. This made the expenditure of power in opening and closing the valve very heavy and wasteful, and was one of the chief reasons for introducing the automatic device. By the use of the balanced circular valve the movements of opening and closing became so easy that they could be readily and rapidly made by hand-power, and as a result the somewhat complex automatic gear was abandoned, the mechanism being entirely operated by hand-gearing only. A patent was taken out for this in 1856.

The next improvement, made with the object of greatly increasing the power of the hammer without increasing the weight of the tup, was introduced in 1861 by Wilson. It is known as the *double-acting hand-gear motion.* In this arrangement steam is admitted under the piston as before to raise it; then just at the instant when the fall is about to take place, by slightly increasing the travel of the hand-lever, steam is admitted into the cylinder above the piston. The effect of this steam-pressure on the top of the piston is to enormously increase the intensity of the blow, and hence the capacity of the hammer, since the hammerhead will descend with much greater velocity, and therefore possess much more energy when it strikes. For example, a double-acting 5-ton hammer may become equal in power to a single-acting 10- or 15-ton one. It should be stated that steam-hammers are commercially rated by the weight of the falling tup, piston, and rod, even when they are fitted to be used as double-acting; so that the power of the blow is not known unless the range of fall is also stated, and whether it is single or double acting.

The figure shows the form of the modern simplified steam-hammer. They are often of great size; 80-ton ones have been made, double-acting, possessing therefore enormous power, as at Essen in Germany and Creusot in France, as well as in the United Kingdom; one in Pennsylvania, the largest made up till 1891, of 125 tons. Of recent years powerful hydraulic presses have been substituted for these big hammers for heavy forging work, but many engineers still prefer the hammering action. In Condie's hammers, a patent for which was taken out in 1846, the piston is stationary, while the cylinder with the tup attached to it is the moving piece. Since the expiration of Nasmyth's patent great numbers of different types of hammers have been put on the market, but they differ from one another principally only in details, the general arrangement being the same. The modern double acting hammer can usually be worked in four ways: (*a*) as a single-acting one, no steam being admitted above the piston, the falling weight therefore alone acting, and again the blow may be made a dead one or a cushioned and elastic one, the latter effect being obtained by admitting steam under the piston before the blow is finished to cushion the piston and cause the tup to rebound the instant it has struck; (*b*) as a double-acting hammer, by using steam-pressure above the piston during the fall, giving also either dead or elastic blows.

Stearin, $C_3H_5(O{\cdot}C_{18}H_{35}O)_3$, is one of the fats occurring in animals and plants. Like the other fats it may be regarded as an ether of the triatomic alcohol glycerine, all three hydroxyl molecules being replaced by radicles of the fatty acid—stearic acid, $C_{18}H_{35}O{\cdot}OH$.

$$C_3H_5\left\{\begin{matrix}OH\\OH\\OH\end{matrix}\right. = \text{Glycerine.} \quad\Big|\quad C_3H_5\left\{\begin{matrix}C_{18}H_{35}O\\C_{18}H_{35}O\\C_{18}H_{35}O\end{matrix}\right. = \text{Stearin.}$$

It is the chief constituent of the more solid fats, such as mutton suet, and is characterised by its high melting-point—from 53° to 66° C.—by its slight solubility in alcohol as compared with palmitin and olein, and by its crystallising from its alcoholic solution in the form of brilliant quadrangular plates. Like the other fats it may be readily split into glycerine and a fatty acid, and if an alkali be present the acid combines with this to form a soap. Stearoptene is the crystalline solid substance which separates from volatile Oils (q.v.) on long standing or at low temperatures. For Physiology of Fats, see FAT.

Steatite, or SOAPSTONE, a compact or massive variety of Talc (q.v.), is a hydrous silicate of magnesia. It is found massive, or sometimes assuming the forms of the crystals of other minerals which it has replaced. It is plentiful in many parts of the world, and is found in various parts of Britain. It is generally white, reddish white, or yellow. It is soft and greasy to the touch, easily cut, but broken with difficulty. It is used in the manufacture of porcelain. It writes readily on glass, and is used by glaziers for marking plates of glass before they are cut with the diamond. Tailors use it for marking cloth before they cut it. It is also used by shoemakers to give unctuosity to the heels of stockings that new boots may more easily be tried on. It is sold for such purposes under the names of Briançon Chalk, French Chalk, and Venice Talc. It readily absorbs oil or grease, and is used in powder for extracting spots of them from silken and woollen stuffs. It is the basis of Rouge (q.v.). It is used for imitating engraved stones, being easily cut, and afterwards hardened by heat; after which it may be coloured by metallic solutions. It also forms a polishing material for serpentine, alabaster, and glass. The so-called Agalmatolite or Pagodite of China, which is carved into images, miniature pagodas, &c., is usually not steatite but a variety of the mineral called Pinite. In other cases it is a compact variety of Pyrophyllite. Now and again it is steatite.

Steatornis. See GUACHARO.

Stedman, EDMUND CLARENCE, American poet and critic, was born at Hartford, Connecticut, 8th October 1833. He studied at Yale and early took to journalism, was war-correspondent of the *New York World* during the war, but ultimately became a stockbroker at New York. He contributed actively to the more important magazines, and published his first volume of verse in 1860. His critical work *Victorian Poets* appeared in 1875, and has gone through many editions. The *Poets of America* appeared in 1886, but naturally proved less interesting. The *Library of American Literature*, edited in conjunction with Ellen M. Hutchinson, completed in 1890, fills 11 volumes. The 'Household Edition' of his poems appeared in 1884.

Steel. The discovery of a material which is capable of cutting and otherwise shaping nearly every other substance known to man, and which can be so modified in hardness as to be able also to easily cut and otherwise shape itself, was of sufficient importance to make a distinct epoch in the progress of the human race. Such a material is steel, which may be made nearly as hard as the diamond, or so soft that it can be cut, bent, or hammered into any shape, rolled into sheets, or drawn into wire even of hair-like thinness. It is composed of iron and carbon, but is not a true chemical compound of these substances. True chemical compounds have fixed and definite proportions of the elements composing them, but steel varies in all proportions from ¼ per cent. of carbon to 2½ per cent. The more carbon the greater becomes the hardness of the steel, until a limit is reached owing to the brittleness which accompanies the hardness. The fusibility of steel increases with the amount of carbon. Ordinary steel contains a little silicon, manganese, sulphur, phosphorus, &c., but these are merely impurities. The removal of these, or their reduction to the smallest possible quantity, is very desirable, as upon such removal the quality of steel mainly depends. These impurities are derived partly from the iron ores and partly from the fuel used in smelting them. When a pure ore, such as the magnetic oxide of iron, and a nearly pure carbon, such as wood-charcoal, are used, the manufacture of steel of fine quality is very simple and easy. With such materials steel is made quite as easily as iron, the carbon of the fuel readily combining with the iron as it becomes reduced from the ore. The ancient iron-makers obtained their steel in this way, and the ironmasters of the East, who still work in the primitive manner with small furnaces and much labour, do the same, but they are not able to accurately regulate the quantity of carbon in the steel and its consequent hardness.

Owing to the scarcity of these pure iron ores and the high cost of charcoal, they are but little used by the modern steel-maker, who adopts a very roundabout process, the true reasons for which have been much misunderstood. He first makes an impure steel (pig-iron or cast-iron) containing 3 or 4 per cent. of carbon, then he reduces this quantity to about $\frac{1}{10}$ per cent. or less in making malleable or wrought iron by puddling (see IRON), and afterwards by another expensive process restores about half as much carbon as he has taken away. Steel has been defined by high scientific authority as 'iron carbonised in degrees intermediate between malleable and cast iron,' a description that has led to a multitude of futile and costly attempts to produce steel by mixing cast and wrought iron together, and other similar devices for simply diminishing the proportion of carbon. Such devices would be successful if cast-iron were a compound or mixture of iron and carbon *only*; but ordinary cast-iron contains silicon, sulphur, and phosphorus in quantities that are ruinous to steel.

The modern maker of the best steel therefore uses the best puddled iron, preferably Swedish charcoal iron. He has it rolled into bars, usually 3 inches wide and ¾ inch thick, and 10 to 15 feet long, and submits these to a process which has received the name of cementing. The cementing-furnace is a circular brick structure terminating upwards in a wide truncated conical chimney of somewhat dome-like appearance, a familiar feature in the gloomy landscape of Sheffield. Fig. 1 shows it in section with the upper part of the chimney cut off: *f* is the ashpit with the bars of the fireplace seen endwise above; *c*, *c* are two 'chests,' or converting pots, shown in section. These are made of firebrick or firestone, and supported over the fire, with flues so arranged that the flame and smoke shall pass up the arched space between them, and below and around their outer sides, so as to heat them all round as equally as possible. The smoke and lurid smoky flame after traversing these flues rise into the arch, *a*, which is thus heated and consequently radiates downwards to the upper side of the chests.

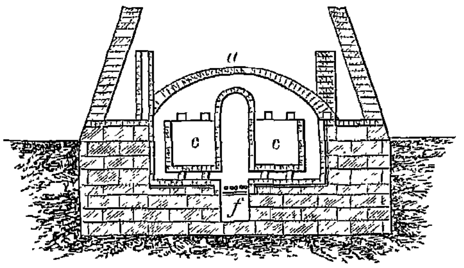

Fig. 1.

The chests, 15 to 18 feet long and 2½ to 3 feet deep and same width, are charged by first spreading over the bottom a layer of coarsely-ground charcoal (from hard wood preferred) about 2 inches deep. Upon this is placed a layer of bars with a space of ½ to ¾ inch between each. Over these bars and into the spaces between them is sifted another layer of charcoal to about an inch deep above the bars; then another layer of bars, and another of charcoal, and so on, up to within 6 inches from the top. Then old 'cement powder'—i.e. charcoal already used, and grinders' waste—is moistened and plastered over this, and the whole covered with clay or moistened sand to exclude the air. All is now closed in excepting the ends of some extra long 'tasting bars,' which are allowed to protrude from the 'tasting' or testing holes. A glowing red heat is maintained for eight or ten days, when a tasting-bar is withdrawn to ascertain whether the carbon has penetrated sufficiently. When this is the case the furnace is allowed to cool slowly during another week or thereabouts. When the bars are withdrawn they are found to be coated with a sort of dark skin which is raised in blisters over a large part of their surface. It is by the appearance of these and by fracture that the quantity of carbon taken in and the depth of its penetration is ascertained. This transfusion or penetration of solid carbon into solid iron is a mystery, the theory of which has been much discussed, too much so for exposition here. An important practical fact is, however, connected with it—*viz.* that the distribution of the carbon is very unequal. Its quantity is greatest on the surface, and gradually decreases towards the interior. Therefore the steel in this state, 'blister steel,' is of little value on account of its irregularity of composition and consequent irregularity of hardness, &c. To remedy this the outsides and insides of the bars have to be stirred up and mixed together so as to give uniformity of composition to the whole.

The most obvious mode of doing this is to melt the whole and stir the fluid. This is done in making the very best quality of steel—'cast-steel' or 'pot-steel,' as it is called in Sheffield. The bars are cut into small pieces, melted in crucibles, and then poured from these into ingot moulds. Oxide of manganese and ferrocyanide of potassium are added in small quantities to the melted metal in the crucibles. The theory of the action of these additions has been much debated, and its discussion would occupy too much space for this article. The consumption of fuel, the labour, and the destruction of crucibles renders this melting an expensive process and the result correspondingly dear. A cheaper mode of mixing is adopted in the production of what is called 'shear-steel.' The blistered bars are cut or 'sheared' into short lengths; these are bound together into bundles or 'faggots,' raised to a welding heat—i.e. heated until they become sufficiently soft to be plastic, then placed under a 'tilt hammer,' shown in fig. 2. The tail of this hammer is struck by the cams of the revolving wheel, whereby the head is lifted, and falls again before the next cam comes into action. In this manner the faggot receives 300 to 400 heavy blows per minute, the rapidity of percussion fully maintaining the heat of the faggot, while its constituent pieces are welded into one coherent mass. This is then rolled out into a long bar which is resheared into small pieces to form another faggot to be similarly treated. The reshearing, &c., may be repeated as often as demanded, and thus we have 'single shear,' 'double shear,' &c. None of these are so homogeneous as crucible steel, and they are therefore inferior in this respect.

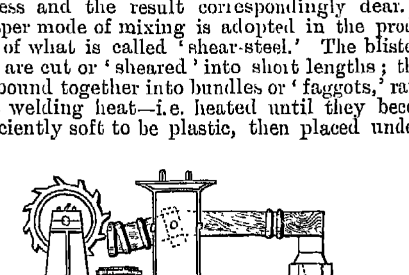

Fig. 2.

A very important development of the manufacture of steel has followed the introduction of the 'Bessemer process,' by means of which a low carbon or mild cast-steel of inferior quality can be produced at about one-tenth of the cost of crucible steel. It is used for rails, for the tires of the wheels of railway carriages, for ship-plates, boiler-plates, for shafting, and a multitude of constructional and other purposes to which only wrought-iron was formerly applied, besides many for which no metal at all was used.

This process was originally based on the theory—then generally accepted—that steel is 'iron carbonised in degrees intermediate between malleable and cast iron;' and, as carbon is readily oxidised at a high temperature and thus converted into gaseous compounds, nothing further was supposed to be necessary for the conversion of cast-iron into steel than to blow through the melted cast or pig iron a sufficient quantity of air to burn out the redundant carbon and leave behind the proportion required for the production of steel. A large number of patents were secured, including various devices for doing this, and all failed. A sort of steel was produced, but it was unworkable. When hammered, either hot or cold, it either crumbled to pieces or split at its edges when flattened down. The sources of failure were twofold. The first was that ordinary pig or cast iron contains other impurities than carbon, notably silicon, sulphur, and phosphorus. The carbon was readily removed by oxidation, and gradually, as demanded by the theory; the silicon was also oxidised even more readily than the carbon, but the sulphur and phosphorus remained obstinately, even after nearly all the carbon was oxidised and the iron itself began to burn. The other difficulty was that of regulating the quantity of carbon, by stopping when the required quantity was removed by oxidation. This difficulty was overcome by Mr Robert Mushet, who used a compound of iron and much carbon of known composition (spiegeleisen), and added this in the quantity necessary to give to the whole the proportion of carbon required. Thus, if the spiegeleisen contained 5 per cent. of carbon, and 1 per cent. was required in the steel to be produced, spiegeleisen was added to the decarburetted iron in the proportion of 1 to 4.

After considerable struggles the first difficulty was partially overcome by using only special kinds of pig-iron, those made from hæmatite ores which contain very little phosphorus. Mr Mushet's 'triple compound,' the spiegeleisen, also assisted here, as it contains a considerable amount of manganese, which exerts a purifying influence on steel. The rationale of this purification has been much debated; the experiments of the writer indicate that manganese acts by removing the last vestiges of silicon and particles of oxide of iron in the Bessemer converter. Its practical usefulness, however, is unquestionable. But the Bessemer steel even thus produced is far inferior to the crucible steel or shear-steel. There is still sufficient phosphorus in it to render it unfit for making tools with acute edges, or for files, saws, &c. If highly carburetted its hardness is accompanied with brittleness that causes cutting-tools to notch, and toothed-tools, like saws and files, to strip. Phosphorus gives hardness of a glassy character.

The Bessemer 'Converter' is shown diagrammatically in section in fig. 3. It is a strong iron vessel lined with refractory material. The bottom, which is removable for renewal, is fitted with fire-clay cylinders, *cd*, *cd*, *cd*, *cd*, and each cylinder is perforated with several holes ½ to ¾ inch in diameter. It is thus riddled with sixty to a hundred holes, according to its size. These perforations communicate by means of an air-chamber, *c*, *c*, *c*, *c*, with a powerful blowing-machine. The whole converter is mounted on an axis, *i*, and may be thereby turned as required.

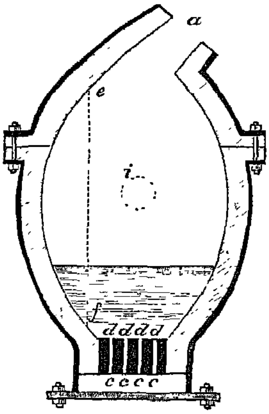

Fig. 3.

The lining is first made red-hot by burning coal within. When thus prepared ready for charging, the converter is turned on the axis, *i*, so that the line, *ef*, shall be horizontal. Molten pig-iron is then poured in at the mouth, *a*, and thus it forms a pool lying in the belly of the converter below the line, *ef*. The blast is now turned on, and the converter turned over to the position shown in the diagram, the melted metal standing over the hundred open holes. It cannot, however, run down these, as the blast of air rushes upwards with much greater force than that of the downward gravitation of the metal. The streams of air tear through the molten metal, and a huge flame roars furiously from the mouth of the converter. With this flame brilliant cascades of coruscating sparks are belched forth at irregular intervals, and the dazzling spray as it dashes against the wall of the flame-shaft rebounds with redoubled splendour. The blast still roars on monotonously, and the flame steadily increases in size and brilliancy, attaining its maximum at about the end of ten minutes. It continues thus for five or ten minutes longer, then the flame contracts. This indicates that the carbon is becoming exhausted, and that the iron, no longer protected by it, is beginning to burn. The converter is now turned to the position in which it was charged, and then the melted spiegeleisen is poured into it. A violent ebullition occurs immediately this mixes with the metal that has been blown, and a great waving blue flame of burning carbonic oxide silently pours out of the mouth of the converter.

Why this violent agitation, and whence comes this great outpouring of gas? The writer studied these questions experimentally when the Bessemer process was young, and found that the carbon is not all burned out, as was then supposed. There remained from ¼ per cent. to $\frac{1}{10}$ per cent. according to the prolongation of the blowing, and besides this there was a considerable quantity of black particles of oxide of iron in the blown metal before the spiegeleisen was added, but after this addition they disappeared. These facts answer the questions. The carbon of the spiegeleisen reduces the black oxide by combining with its oxygen, and this combination with oxygen produces the carbonic oxide. The manganese assists, for much of it disappears from the metallic product, and is found in the liquid cinder (or 'slag') combined with oxygen and silica. The blown metal, before the addition of the spiegeleisen, is 'rotten;' it breaks under the hammer whether hot or cold. If overblown it crumbles like sandstone.

One of the most remarkable phenomena of the Bessemer process is the intense heat to which the metal is subjected. It far exceeds that obtained in any other melting furnace. At first glance this may appear strange, as nothing but cold air is applied to the melted metal. But this metal is pig-iron containing silicon and carbon. Both of these are effective fuels when heated and supplied with oxygen. The manganese adds a little. In an ordinary charge of six tons of average material these fuel substances amount to about 8 cwt. They are all burned in the course of about twenty minutes, not outside a melting-pot, but within or amidst the melted metal itself; and thus the heat of this extraordinary amount of combustion in so small a space is rendered exceptionally effective. After the spiegeleisen is all added and well admixed by the agitation it produces, the liquid steel is poured into ingot moulds of suitable sizes according to its purpose, and these are wrought by hammering, rolling, &c. as required.

Owing to the phosphorus contained in ordinary Bessemer steel, it will rarely bear as much as 1 per cent. of carbon without becoming worthlessly brittle, and therefore only mild or low carbon steel is made from it for purposes already stated. Messrs Thomas and Gilchrist have succeeded in removing the most of this residual phosphorus by lining the converter with a basic material, a refractory substance in which lime and magnesia preponderate. These bases eagerly combine with phosphoric acid at high temperatures, and by their predisposing affinities assist the phosphorus in combining with the oxygen of the blast to become the phosphoric acid which they demand. The phosphates of lime and magnesia thus obtained are valuable manures. The practical value of the basic process depends mainly on its rendering impure pig-iron available.

The 'Siemens-Martin process' is now competing very effectively with the Bessemer process. It consists essentially in first obtaining a bath of melted pig-iron of high quality, and then adding to this pieces of wrought-iron scrap or Bessemer scrap, such as crop ends of rails, shearings of plates, &c. These, though practically infusible in large quantities by themselves, become dissolved or fused in such a bath if added gradually. To the bath of molten metal thus obtained spiegeleisen or ferro-manganese is added to supply the required carbon and to otherwise act as already described in the Bessemer converter. The result is tested by small ladle samples, and when it is of the desired quality a portion is run off, leaving sufficient bath for the continuation of the process.

It is evident that here a high degree of purity is attainable by selection of the scrap, which may be of high quality wrought-iron from which the impurities have been removed by puddling. Very fine samples of 'homogeneous metal' have thus been obtained, resembling wrought-iron in softness and toughness, with some degree of the high tenacity of cast-steel. Where qualities like those of ordinary Bessemer metal are required, this process supplies an economical method of melting up and utilising such materials as old Bessemer rails, &c.

Tempering.—The special property upon which the great value of steel depends is that of being capable of acquiring various degrees of hardness. These are obtained by what is commonly called 'tempering,' which really includes two processes—(1) hardening and (2) tempering properly so called. If a piece of steel containing ½ per cent. of carbon and upwards is made red-hot and then suddenly plunged into cold water, or otherwise rapidly cooled, it becomes hardened in proportion to the quantity of carbon it contains. In this condition it is of very little use, as it becomes brittle in proportion to its hardness; but this brittleness and extreme hardness may be tempered by reheating in various degrees according to the degree of hardness required. This is the *tempering* process properly so called.

The workman has discovered a simple and elegant means of determining the temperature attained in this reheating. A film of oxide is formed, and as this thickens its colour changes as shown in the table below. Another method of fixing the temperature is by immersing the tool in a bath of fusible metal or alloy just at its melting-point, which melting-point varies with the composition of the alloy. A third is to smear the surface with tallow and watch the result. The following table shows these results, the temperature at which they occur, and the alloys that may be used.

	Colour.	Temperature.	Alloy.	Effect on Tallow.
1.	Pale straw....	420° F.	7 lead 4 tin	Vaporises.
2	Straw	450°	8 " 4 "	Smokes.
3.	Straw yellow..	480°	8½ " 4 "	More smoke.
4.	Nut brown...	500°	14 " 4 "	Dense smoke.
5.	Purple...	530°	19 " 4 "	Black smoke.
6.	Bright blue...	580°	48 " 4 "	Flashes if light is applied.
7.	Deep blue ...	590°	50 " 2 "	Continuous burning.
8	Blackish blue .	640°	All lead or boiling linseed-oil.	All burns away.

Long exposure to the temperatures named has an effect similar to that of a higher temperature. The usual practice is to plunge the article into cold water immediately the required temperature is reached, and the above table is based on this practice. Varying temperatures, or degrees of softening or 'letting down,' are demanded according to the purposes for which the tool is used. No. 1—pale straw—is the temper for tools used in cutting iron and steel, for lancets and some other surgical instruments. Nos. 2 and 3 for tools used in cutting brass. No. 3 for penknives and tools of this class. No. 4 for scissors, stone-masons' chisels, and the strongest tools used for cutting hard wood. No. 5 for table-knives, clasp-knives, and ordinary edged tools for cutting soft wood. No. 6 for swords, bayonets, axes, &c. No. 7 for watch-springs, needles, fine saws, and other tools where elasticity is demanded. This is called 'spring-temper.' No. 8 for common wood-saws, and other tools used for soft material. Steel is softened by heating to redness and cooling very slowly (see ANNEALING). See *The Chemistry of Iron and Steel Making*, by the present writer (1890).

Steelbow (a word of doubtful origin), in Scots law, means goods, such as corn, cattle, straw, and implements of husbandry, delivered by the landlord to his tenant, by means of which the latter is enabled to stock and labour the farm, and in consideration of which he becomes bound to return articles equal in quantity and quality at the expiration of the lease.

Steele, SIR RICHARD, the father of the Queen Anne essay, was born in Dublin in March 1672 (n.s.), and was there baptised at St Bridget's Church. His father, Richard Steele of Mountain (Monkstown), was an attorney; his mother had been a widow named Elinor Symes. His father died when he was a child (*Tatler*, No. 181). Mrs Steele did not long survive her husband, and the boy fell to the charge of an uncle, Henry Gascoigne, secretary to the first Duke of Ormond. Through Ormond's influence, in November 1684 Steele was placed upon the foundation at the Charterhouse, where he had Addison, his junior by six weeks, for contemporary. In December 1689 he entered Christ Church College, Oxford, and in March 1690 he matriculated. He tried hard for a Christ Church studentship, but eventually (in 1691) gained a postmastership at Merton. At the university he was popular and respected, but in 1694 he suddenly enlisted as a cadet in the second troop of Horse Guards, then commanded by the second Duke of Ormond, thereby surrendering, according to his own account, some rather vaguely described expectations as a Wexford landowner. Already at college a dabbler in verse, in 1695 he made his appearance as a printed poet by *The Procession*, a conventional effusion on the funeral of Queen Mary, which he dedicated to John, Lord Cutts, who forthwith made him his secretary, and finally gave him a standard in his own regiment of Coldstream Guards. In June 1700 he became involved in a duel with an Irishman named Kelly, whom he had the misfortune to wound severely. One outcome of this occurrence was the production of the devotional manual known as *The Christian Hero*, which was written at the Tower Guard, and published in April 1701. With the public it was popular, but, as might be anticipated, it was regarded by Steele's military comrades as incompatible with his calling as a 'gentleman of the army.' 'From being thought no undelightful companion,' he 'was soon reckoned a disagreeable fellow;' and the necessity to 'enliven his character' drove him to the odd expedient of writing a play. This, *The Funeral; or, Grief à la Mode*, was acted at Drury Lane in December 1701. It was followed in 1703 by *The Lying Lover*, and in 1705 by *The Tender Husband*. About this time, it is supposed, being now a captain in Lord Lucas' Regiment of Foot, he engaged in certain researches for the 'philosopher's stone,' the details of which rest mainly upon the authority of that 'cornucopia of scandal,' the *New Atalantis* of Mrs De la Rivière Manley, although the fact of the researches is not denied. Their failure is practically synchronous with his marriage to a widow named Margaret Stretch (with estates in Barbadoes). The marriage took place in 1705, and the lady died two years later. In August 1706 Steele was appointed gentleman-waiter to Queen Anne's consort, Prince George of Denmark; and a few weeks after his wife's death, upon the recommendation of Arthur Mainwaring (who, like Steele, was a member of the Kit Cat Club), he was appointed by Harley, then a Secretary of State, to the post of Gazetteer, the annual salary of which was increased to £300. By this time, it is presumed, he had quitted the army; but he continued to be spoken of as 'Captain' Steele. The next notable occurrence in his life was his second marriage, in September 1707, to the beautiful Miss Mary Scurlock, the daughter of Jonathan Scurlock, deceased, of Llangunnor in Carmarthen, and the 'Prue' of her husband's correspondence. Shortly afterwards, by the death of Prince George, he lost his court appointment. Then, without much warning, appeared on the 12th April 1709, the first number of the famous tri-weekly paper known as the *Tatler*, the putative author of which was one 'Isaac Bickerstaff,' a pseudonym borrowed from Swift. In January 1710, during the course of the *Tatler*, Steele was made a commissioner of stamps, and for some obscure reason was deprived of his gazetteership. The *Tatler* came to an end on 2d January 1711, to be succeeded in March by the more famous *Spectator*, which ceased 6th December 1712. To the *Spectator*, in March 1713, followed the *Guardian*. In all these enterprises Steele enjoyed the aid, as a contributor, of his friend and schoolfellow Addison—an aid the incalculable value of which he acknowledged with loyal cordiality. 'I fared (he said) like a distressed prince, who calls in a powerful neighbour to his aid; I was undone by my auxiliary; when I had once called him in, I could not subsist without dependence on him' (Preface to *Tatler*, vol. iv.).

In beginning the *Guardian* Steele had made prudent profession of abstinence from political questions. But the moment was not favourable to restraint, even for less earnest men. From his youth he had been an ardent adherent of the Revolution, and now, as it was thought, the Hanoverian succession was in jeopardy. Before April 1713 he was involved in a bitter quarrel with Swift. Then the disquieting rumours that the demolition of the Dunkirk fortifications, which was provided for by the treaty of Utrecht, would not be insisted on drew from him an indignant pamphlet entitled *The Importance of Dunkirk consider'd*, to which Swift, on the other side, grimly retorted with *The Importance of the 'Guardian' consider'd*. Steele in the meantime had resigned his commissionership of stamps, and entered parliament as member for Stockbridge, concurrently dropping the *Guardian* for the professedly political *Englishman*. Shortly afterwards he published *The Crisis* (1714), a pamphlet on the Hanoverian succession, to which Swift replied with matchless irony by *The Publick Spirit of the Whigs*. When Steele actually entered upon his duties in the House he found he was a marked man. He was promptly impeached for seditious utterances in *The Crisis*, and, although he made a capable defence, was expelled. But with Anne's death, a few months subsequently, his party came into power and his troubles ended. In his best pamphlet, *Mr Steele's Apology for Himself and his Writings* (1714), he has given his own account of this part of his career.

That career, as far as literature is concerned, practically closed at this point. He again became a member of parliament, being returned for Boroughbridge; and a little later, upon presentation of an address to King George I., was knighted. He continued to produce periodicals and pamphlets, none of which are of great importance, though one of them, *The Plebeian*, had the effect of involving him in a painful controversy with his friend Addison. He was made a patentee of Drury Lane Theatre, where in 1722 he produced *The Conscious Lovers*, his best comedy. He also established the *Censorium*, a sort of æsthetic music-hall; and he devised an impracticable 'fish-pool' or well-boat for bringing salmon alive from Ireland. In December 1718 he lost his wife. He survived her for nearly eleven years, dying ultimately, 1st September 1729, at Carmarthen, where he was buried in St Peter's Church. Of his four children only two were living at his death. His daughter Mary soon followed her father; and the remaining and eldest child, Elizabeth, married a Welsh judge, afterwards the third Lord Trevor of Bromham.

Steele's character has suffered from various causes, among which may be reckoned the animosity aroused by his political writings, the careless candour of his own admissions of frailty, and the habitual comparison of his weaknesses with the colder and more equable goodness of Addison. He has been specially branded as intemperate, but there is no sufficient evidence why in this respect he should be singled out from his contemporaries. That he was incurably sanguine, and that he constantly mistook his expectations for his means, is manifest from his lifelong embarrassments. But these were the result of an improvident temperament and an uncertain income rather than of a vicious habit of mind; and he made a noble and successful attempt to pay his debts before he died. Upon the whole he was a warm-hearted and benevolent man, a devoted husband (some of his letters to his wife are among the most unfeigned in the language), a loving father, and a loyal friend.

As a literary man he may be more exactly estimated. Though he wrote verse, he has no claims as a poet. His plays are commendable efforts in the direction of the stage-purification advocated by Jeremy Collier; but their feeling for humorous character is more notable than their stage-craft, and they have never kept the boards. His political pamphlets were honest and straightforward, but not effectively polemical; and he had a terrible enemy in Swift, who as a former friend had learned his adversary's weakest side. His fame rests almost wholly upon his performances as an essayist. And here he was by no means the colourless colleague of Addison that is sometimes supposed. On the contrary, he was nearly always the fore-running and projecting spirit, and his ready sympathies and quick enthusiasm occasionally carried him to an altitude which Addison never attained. If he wanted Addison's restraint, his distinction, his exquisite art, he nevertheless rallied folly with admirable good-humour, rebuked vice with unvarying courage and dignity, and earned for himself the lasting gratitude of the 'beautiful sex,' as he called them, by the chivalry, the manliness, and the genuine respect with which, almost alone in his age, he spoke of women.

Steele has been written of by Macaulay (*Edinburgh Review*, 1843) and Thackeray (*English Humourists*, 1853), but most sympathetically by John Forster (*Quarterly Review*, 1855). In 1886 a Memoir of him, containing some new facts, was issued by the present writer in the 'English Worthies' series; and in 1889 followed a detailed Biography by Mr G. A. Aitken, embodying the results of prolonged and minute researches. A selection from Steele's Essays, with notes, was issued in 1885 by the Clarendon Press.

Steell, Sir John, R.S.A., sculptor, was born at Aberdeen in 1804, the son of a carver and gilder. He received his education as an artist at the Edinburgh Academy, and afterwards at Rome. In 1832 he modelled 'Alexander and Bucephalus,' which, however, was not cast in bronze until 1883, being erected in Edinburgh the year after. The promise of this early work he subsequently fulfilled. Most of his chief works are in Edinburgh: the colossal figure of the Queen crowning the front of the Royal Institution, which procured him the honorary appointment of Sculptor to Her Majesty in Scotland; the statue of Scott in the Scott Monument; the equestrian statue of the Duke of Wellington (1852); statues of Professor Wilson, Allan Ramsay (1865), and Dr Chalmers (1878); and the equestrian statue of Prince Albert, at the inauguration of which in 1876 Steell was knighted. Other works, in bronze or marble, are statues of Admiral Saumarez in Greenwich Hospital; of the Marquis of Dalhousie at Calcutta; of Sir Walter Scott (1872) at New York; and of Burns at New York (1873), Dundee, and London. He died 15th September 1891.

Steelton, a borough of Pennsylvania, on the Susquehanna River, 4 miles by rail SE. of Harrisburg, with large Bessemer steel-works. Pop. (1880) 2447; (1890) 9250.

Steelyard. See Balance.

Steen, Jan, Dutch painter, the son of a Leyden brewer, was born in that city in 1626, went (it is believed) to Haarlem about 1644 and studied under Adrian van Ostade, joined the Leyden guild of painters in 1648, for some time carried on the trade of a brewer at Delft, and died in his native city in 1679. Steen was a painter of the same stamp as Rembrandt. A sympathetic observer of human life, he painted genre-pictures from every plane of life, the lowest as well as the highest. Although there is a decided ethic leaven in his work, it is softened by the spirit of sympathetic toleration and lightened by the play of comedy. The grave humour of his style is best seen in such pictures as the 'Doctor Visiting his Patient,' a 'Cavalier giving Lessons on the Guitar to a Lady,' 'Domestic Life,' 'Tavern Company,' 'The Oyster Girl,' 'Work and Idleness,' 'Bad Company,' 'Old

Age,' and particularly the pieces of childhood (e.g. the pictures called 'St Nicholas' and 'Twelfth Night'). See F. Wedmore in *Temple Bar*, vol. li.

Steenstrup, Johannes Iapetus Smith, zoologist, was born at Vang in Norway on 8th March 1813, taught on mineralogical subjects at Soro in Denmark, and from 1845 to 1885 was professor of Zoology at Copenhagen and director of the zoological museum. His books treat principally of hermaphroditism in nature, alternation of generations, flounders' eyes, and Cephalopods. He also took a keen and active interest in exploring the turf-moors and kitchen-middens of Denmark for evidences of prehistoric times.—His son, Johannes Steenstrup (b. 1844), professor of Northern Antiquities at Copenhagen, has written a good book about Viking life and times, *Normannerne* (1876-82).

Steeplechase, a horserace run not on a course of smooth, flat turf, but across the open country, over hedges, ditches, walls, and whatever other obstacles lie in the way. This variety of sport seems to have had its origin (traditionally) in the frolic of a merry party of foxhunters, who agreed to race in a straight line towards a steeple visible in the distance, an event which is recorded to have happened in Ireland in 1803; further particulars of it, however, are not known. Nevertheless this was not the earliest race of the kind. One took place in Ireland in 1752 from the church of Buttevant (Cork county) to the church of St Leger, a distance of 4½ miles. In the year 1816 a ride in England of 20 miles across country against time (under one hour and nine minutes) was regarded as something extraordinary, although about that time steeplechase matches were coming into fashion with the young foxhunters of the day. The sport began to assume its existing shape about the year 1831. In 1866 the Grand National Hunt Committee was formed for the purpose of laying down rules and regulations for the proper conducting of steeplechase meetings. The principal race in this class of sport in the United Kingdom is the Grand National, which was instituted at Liverpool, the headquarters of steeplechasing, in 1839; it is now run on different courses in different years. Among the more important steeplechase meetings are those of Liverpool, Newport Pagnell, St Albans, Aylesbury, Lincoln, Brocklesby, and Leamington. Steeplechase races have always been greatly in favour in Ireland. See A. Coventry and A. E. T. Wilson in the volume on *Horseracing and Steeplechasing* (1889) in the 'Badminton' series.

Steeple-Jack is the popular name for a stonemason or plumber who makes it his business to repair steeples and chimney-stalks. See article in *Chambers's Journal,* 1890.

Steering is the act of maintaining or altering the direction in which a vessel is proceeding. This control of a vessel's direction is usually effected by a stern *rudder*, which, as ordinarily fitted, swings on the vessel's stern-post, and can be set at any required angle with the vessel's fore and aft line. The rudder is turned by what is in effect a lever called the *tiller*, or *helm*, which is secured to the rudder-head, and either projects forward from the rudder-head (as is often the case in boats and small vessels) or projects aft from the rudder-head (as in most large vessels). The tiller may in some cases be grasped and turned by hand; but in general a wheel with axle and wheel chains is used to turn the tiller. Where steam-steering gear is fitted it is controlled by a small steering-wheel. When on board a vessel and looking forward—i.e. towards the bow—the right-hand side of the vessel is called the *starboard* side, and the left hand the *port* side. The port side was formerly called the *larboard* side. The order 'port the helm' demands that the after part of the stern rudder should be swung round towards the *starboard* side of the vessel. Where there is a free tiller projecting forward from the rudder-head this is, of course, accomplished by moving the free end of the tiller towards the *port* side of the vessel, and this gave rise to the terms of the order. Where a wheel is used the intermediate gearing is usually so fitted that to 'port the helm' the top spoke of the wheel must be pulled down towards the *starboard* side of the ship. The effect produced in the way of turning the vessel where 'the helm is ported' is as follows: in the case of a sailing-vessel or of other vessels whose propellers are not placed at or near the stern, the hull is turned so that the head of the vessel *appears to turn towards its own starboard side* when the hull is moving ahead, and towards its own port side when the hull is moving astern; but in the case of vessels whose propelling apparatus works in the water at or near the stern, the first turning effect named is produced when the propeller (and not necessarily the hull) is going ahead, and the second turning effect is produced when the propeller (and not necessarily the hull) is going astern. The effect of the order to 'starboard the helm' is precisely the opposite of all this. The sailors of some foreign nations obey these orders by putting the wheel the opposite way to the above (the British) usage.

The kind of rudder called the 'balanced rudder' has about one-third of its area before the axis about which the rudder rotates. *Bow rudders*, as well as stern rudders, have been fitted to river-boats, telegraph-laying vessels, ferry-boats, &c., where such vessels are required to run with either end first. In this case one rudder is locked while the other is in use. *Two rudders astern* have also been recently tried with good effect. In regard to the *effect produced upon the steering by the propeller or propellers*, the adoption of twin screw-propellers, one on each side of the mid-ship line, has enormously increased the rapidity of steering by working one propeller only, or by simultaneously working one ahead and the other astern. A single screw-propeller has of itself a twisting action on the hull, more especially when the propeller is going astern, the effect being in the latter case to apparently turn the ship's head towards her own starboard side with a right-hand propeller, and towards her own port side with a left-hand propeller. In all these cases, while it is usual to speak of the rudder, propeller, &c. turning the ship's *head*, it is probable that most of the turning effect is the result of the ship's *stern* turning the opposite way from the apparent direction in which the ship's head turns. For steering racing and other boats, see Rowing, p. 10. See also Boat, Yacht, Rule of the Road.

Steevens, George, Shakespearian commentator, was born at Stepney in 1736, the son of an East India Company director, and became a foundationer at Eton and scholar of King's College, Cambridge. He was kept in hot water all his days through his meddlesome and sarcastic temper and his dishonourable habit of making bitter attacks on his friends from behind the anonymity of newspapers like the *St James's Chronicle* and the *Critical Review*. Johnson's judgment was almost too lenient when once, in reply to Beauclerk's assertion 'He is very malignant,' he said, 'No sir, he is not malignant. He is mischievous, if you will. He would do no man an essential injury; he may indeed love to make sport of people by vexing their vanity.' At another time Johnson hit him off in the phrase, 'He lives like an outlaw.' Another favourite trick of Steevens was to set up mock commentators, as Amner and Collins, on whom to father dirty annotations he did not wish to own. Steevens died at Hampstead, 22d January 1800, and was buried at Poplar under one of Flaxman's monuments. He began his literary life in 1766 with a reprint from the original quartos of *Twenty of the Plays of Shakespeare* (4 vols.). This work caused him to be employed as collaborator with Johnson in his edition (1773). Of this latter work a second edition appeared in 1778, to which Malone had contributed, and the latter printed in 1780 by way of supplement the doubtful plays and the poems, an act of independence which the jealous Steevens could not endure. Steevens now set to work, with the help of Isaac Reed, upon a completely new edition of Shakespeare (1793; 1803), in which 'instead of a timid and servile adherence to ancient copies,' is adopted the 'expulsion of useless and supernumerary syllables, and an occasional supply of such as might fortuitously have been omitted.' This doctored text held its authority till the publication of Malone's posthumous edition, the famous *Variorum Shakespeare* (ed. by Boswell, 21 vols. 1821). In his great edition Steevens did not print the poems of Shakespeare, 'because the strongest act of parliament that could be framed would fail to compel readers into their service.'

Stein, CHARLOTTE VON, the intimate friend of Goethe (q.v.), was born at Weimar on Christmas Day 1742, and married in 1764 to the Duke's Master of the Horse. Her friendship with Goethe was broken suddenly after the poet's return from Italy (1788). They were, however, in some measure reconciled before Frau von Stein died, at Weimar, on 6th January 1827. Goethe's Letters to her were first published in 1848-51, and again, with additions, in 1883-85; and another final collection was issued by the German Goethe Society in 1886. The lady's letters to Goethe were destroyed by her shortly before her death.

See Hofer, *Goethe und C. von Stein* (1878), and Düntzer's defence of her, *C. von Stein* (1874).

Stein, HEINRICH FRIEDRICH CARL, BARON VOM, Prussian statesman, was born at Nassau on 26th October 1757. He prepared himself for public life at Göttingen (1773-77), and entered the service of Prussia in 1780. In four years he had risen to be the administrative head of the mines in Westphalia, and in 1796 was appointed president of the Westphalian chambers. In 1804 he was summoned to take charge of the department that had the control of the excise, customs, manufactures, and trade; but though he succeeded in getting the restrictions on internal commerce abolished, and effected some minor improvements, he was unable to modify the traditional and favourite methods of governing current in Prussia. At length the king and his minister could no longer work together, and Stein tendered his resignation (January 1807). Whilst living in retirement at Nassau he wrote an essay on administrative reform, in which he outlined the measures which he subsequently carried into effect. After Frederick-William III. had drunk the bitter dregs of his policy in the treaty of Tilsit, he saw no other alternative except to recall the man whom he had so despitefully used, especially as this step was recommended to him by his conqueror Napoleon. Accordingly Stein resumed office before the year ran out. He at once set to work with the swiftest energy, and in little more than a twelvemonth wrought such changes as laid the foundations of Prussia's subsequent greatness. His aim was to root the sovereign power in the hearts and wills of the people, and to make them free and responsible political actors. To this end he promulgated measures which abolished the last relics of serfdom, did away with the privileges of caste, freed the sale and purchase of land from the rusty shackles of feudalism, created on the lands of the crown a class of peasant proprietors, and abolished all monopolies and other hindrances to free trade. At the same time he framed a scheme of municipal government which liberated the citizens from the military bureaucracies, and he warmly supported Scharnhorst (q.v.) in his schemes of army reform, which converted the Prussian troops into a disciplined body of citizen-soldiers. Other wide-reaching reforms he was unable to carry out himself, because Napoleon, at length realising the character of the man he had recommended, insisted upon his dismissal, and even confiscated his family estates in Westphalia. Stein quitted (November 1808) his post and withdrew to Austria, but not before issuing his *Political Testament*, a forecast of the changes Prussia needed to undergo. Not feeling himself quite secure in Austria, he accepted an invitation to St Petersburg (1812), and, although he refused to enter the czar's service, he was actively instrumental in cementing the coalition against Napoleon, and in animating the Germans in their final uprising. From the momentous battle of Leipzig to the Congress of Vienna he was the ruling spirit of the opposition against Napoleon. After the congress closed, Stein, who was dissatisfied with its conclusions, gradually withdrew into private life; a period of tranquillity and especially of reaction, like that which soon set in in Prussia, was not suited to a man of his strong and downright character. The principal fruit of his leisure was the establishment (1819) and organisation of the society that has printed the great collection of historical documents known as *Monumenta Germaniæ Historica*. Stein died at his country-seat of Kappenberg in Westphalia on 29th June 1831, the last male of his race, as he left only daughters by his wife, a granddaughter of George II. of England.

See Pertz, *Leben des Ministers Freiherrn vom Stein* (6 vols. 1849-55); Professor Seeley's *Life and Times of Stein* (3 vols. Camb. 1878); and the *Erinnerungen* of General von Boyen (1891).

Steinbock. See GOAT, ANTELOPE.

Steinkerk, or STEENKERKE, a village in the Belgian province of Hainault, 5 miles N. of Soignies, was the scene of William III.'s defeat by the French under Marshal Luxembourg, on 3d August 1692. Pop. 860.

Steinmetz, CARL FRIEDRICH VON, Prussian general, born at Eisenach on 27th December 1796, fought through the campaign of 1813-14, winning the iron cross for valour, and in the war of 1866 routed three successive Austrian corps (June 27-29). On the outbreak of the Franco-German war of 1870 he was put in command of the right wing of the German advance; but he proved unequal to the task committed to him, especially at Gravelotte, and after that battle was nominated governor-general of Posen and Silesia. He died at Bad Landeck on 4th August 1877.

Steinthal, HEYMANN, was born at Gröbzig in Anhalt, 16th May 1823, studied philology and philosophy at Berlin, and from 1850 became a lecturer in the science of Language and Mythology. The years 1852-55 he gave to the study of Chinese at Paris, and in 1863 became an extra-ordinary professor of the science of Language at Berlin, from 1872 also lecturing at the Jewish High School on Old Testament criticism, ethics, and the philosophy and history of religion. His writings bear the stamp of a powerful intellect and of learning remarkable at once for profundity and width of range. In his method he shows strongly the influence of W. von Humboldt, and he himself edited the philological writings of his master (1884).

Among his works are *Der Ursprung der Sprache* (1851); *Klassification der Sprachen* (1850), worked up later into the important book, *Charakteristik der hauptsachlichsten Typen des Sprachbaues* (1860); *Die Entwickelung der Sprache* (1852); *Grammatik, Logik, Psychologie* (1855); *Geschichte der sprachwissenschaft bei den Griechen u. Romern* (1863); *Die Mande-Negersprachen* (1867); *Allgemeine Ethik* (1885), &c. With Lazarus he edited from its foundation in 1860 the *Zeitschrift fur Volkerpsychologie und Sprachwissenschaft.*

Stella. See SIDNEY (PHILIP), and SWIFT.

Stellaland, a short-lived South African republic, formed in 1882 by the Boer adventurers who supported Massouw, a chief of the Batlapins, against his rival Mankoroane, who relied upon the British. In 1884 the British government assumed the administration of the country, and in the following year annexed it and incorporated it in the new colony of Bechuanaland (q.v.). See Mackenzie's *Austral Africa* (1887). The capital is Vryburg, connected by rail with Kimberley.

Stellerine. See RHYTINA.

Stelvio, PASS OF THE (Ger. *Stilfserjoch*), the highest carriage-road across the Alps (9042 feet), leads from Bormio, near the head of the Italian Valtelline, to Spondinig in the Vintschgau valley of the Austrian Tyrol. It forms part of the great road between Milan and Innsbruck, and was completed by the Austrian government in 1825. It has a length of 33 miles, and is remarkable for its magnificent scenery.

Stem, the ascending axis of a plant, which usually bears leaves and flowers, and maintains communication between the roots and the leaves. In the Thallophytes—seaweeds, liverworts, &c.—no stem is differentiated; it begins among the mosses, grows stronger in the ferns, horsetails, and club-mosses, and attains its highest development in such trees as pine, palm, and oak. In these trees and in all other Phanerogams the stem results from the growth of the embryonic plumule.

Stems vary greatly in general habit; they may be upright and unbranched as in palms, or upright and much branched as in the oak; they may be scramblers as in the bramble, or twiners as in the hop, or climbers as in the ivy and Virginian creeper; they may be prostrate as in the strawberry, or underground root-like 'rhizomes' as in the Iris. Their usual function of lifting the leaves and flowers off the ground into the fresh air and sunlight may thus be lost, or subordinated to some other function, such as storage of nutritive material, as in the 'corms' of the crocus and 'tubers' of the potato, or storage of water, as in some succulents. When the rind is green it may assimilate as leaves do, and this is very important in such stems as those of cactuses, whose leaves are reduced to spines. It may also happen that branches of the stem are modified into flattened, leaf-like phyllodes as in Ruscus, into thorns as in the hawthorn, into tendrils as in the vine.

The stem is in many ways markedly contrasted with the descending axis or root, but few of the distinctions are rigid. Thus, most stems have some chlorophyll, which is absent from roots except perhaps in the case of one or two of aerial habit. Stems usually bear leaves, which roots never do. The tip of a stem is almost invariably a naked-growing point, while that of a root is usually protected by a root-cap. The branches of a stem arise as superficial outgrowths (exogenous buds), while rootlets arise endogenously from rudiments which develop in an internal layer known as the pericycle. The stem has a persistent tendency to grow upwards, while the root seeks the centre of the earth, and in regard to other forces than that of gravity, stem and root usually behave in opposite ways (see PLANTS, MOVEMENTS OF).

In describing aerial stems we distinguish the nodes from which the leaves arise from the intervening internodes, the buds which appear in the axils of leaves from that which forms the apex, or from those which appear arbitrarily or adventitiously, the leaf-bearing branches from the flower-stalks, and so on. The branching of the stem is usually lateral, but there are divergent forms, such as false dichotomy in the mistletoe, false axis in the vine, or true dichotomy in some Lycopods (see BRANCH).

In order to present a clear picture of the internal structure of a stem, it will be convenient to restrict our attention in the first place to the young twigs of some Dicotyledonous tree, such as the oak.

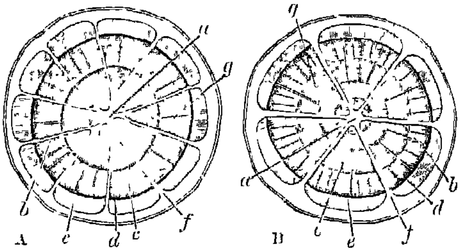

Fig. 1.—Diagrammatic cross sections of a young Dicotyledonous Stem:

A, a two-year old stem; B, a three-year old stem: *a*, pith; *b*, primary medullary rays; *c*, wood, in two layers in A, in three layers in B; *d*, cambium ring; *e*, bast; *f*, cambium (interfascicular) between the bundles; *g*, secondary medullary rays.

Every one knows that it is easy to peel off the 'bark' and to leave the white wood bare. This is possible because the region known as the bark is separated from the internal wood by a cylinder of delicate, readily ruptured, actively dividing cells—the 'cambium.' When a ring of bark is cut off a tree, the leaves do not wither; therefore we conclude that the water which ascends from the roots passes up by the wood. But if in the 'ringing' the young wood be also cut, the leaves wither rapidly; therefore it is by the young wood that the water ascends—a conclusion corroborated by the fact that a tree may flourish well although its heart-wood has rotted away. But the wood includes many different kinds of elements—long vessels, tracheide cells, wood-parenchyma, and wood-fibres. It is certain that the younger tracheides and vessels are the paths for the ascent of the water. Again, if we tie a string very tightly around a stem so as to compress the bark, the stem sometimes swells just above the stricture; and if there be a fruit growing from the stem on that region, it will increase greatly in weight. This suggests that the nutritive materials elaborated in the leaves pass down outside the wood. But the tissue outside the wood and the cambium cylinder includes many different kinds of elements—an external epidermis, perhaps some cork, some softer rind or cortex, a set of hard bast-fibres, and, most internally, what is called soft-bast, including long 'sieve-tubes' and also 'cambiform-cells.' It is certain that this soft-bast is very important in the downward passage of elaborated sap.

If we examine—by means of thin sections—the delicate growing point of the stem, we find that it consists of an external epidermis and of an almost homogeneous 'fundamental tissue.' As we pass in our examination from the tip downwards—that is, to slightly older parts—we notice that within the fundamental tissue there gradually appear certain firm strands. These differentiations of the fundamental tissue are known as fibro-vascular bundles. Thus in the stem we distinguish the epidermis, the fibro-vascular bundles, and what remains of the fundamental tissue, in the form of central pith and superficial cortex, and radiating plates or medullary rays extending between these. In Dicotyledons the fibro-vascular bundles are radially arranged, and each consists of an internal wood or xylem part, an external bast or phloem part, and between these a persistent young layer of cambium, which, by the division of its cells, adds internally to the wood, externally to the bast, and enables the stem to grow in girth. These fibro-vascular bundles are continued out into the leaves, or, to state the fact in another way, each leaf contributes to the stem a ‘leaf-trace’ of fibro-vascular bundles which extend vertically down the stem, and eventually unite in a connected system. In the lower or older parts of the twig or stem there are necessarily very many fibro-vascular bundles, and these are intimately fused with one another. Thus we have from without inwards, beneath the cortex, a sheath of bast, a cylinder of cambium, and the central wood. The fundamental tissue remains undifferentiated in the cambium, and slightly modified in the central pith (if that be present), in the radial medullary plates which traverse the wood and bast, and in the superficial cortex.

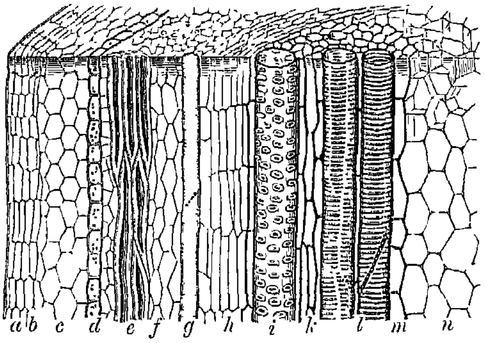

Fig. 2.—Longitudinal section of a portion of a woody Stem (after Kerner).

a, epidermis; *b*, cork; *c*, cortical parenchyma; *d*, bundle-sheath; *e*, hard-bast; *f*, bast-parenchyma, *g*, sieve-tubes; *h*, cambium; *i*, vessel with bordered pits; *k*, wood-parenchyma; *l*, vessels; *m*, medullary sheath; *n*, pith.

The fibro-vascular bundles in the stem of Dicotyledons have a radial arrangement; in their vertical course they run parallel to one another, and are united into a connected system. Almost always they are ‘collateral’—i.e. the bast lies in the same radius as the wood—and they are ‘indefinite,’ for the cambium persists. In Monocotyledons the fibro-vascular bundles which enter from the leaves pursue a curved course—first inwards and then outwards again—in the stem. In cross sections they therefore appear scattered in the fundamental tissue; they are also collateral but ‘definite,’ for the cambium is at an early stage used up. This last peculiarity explains the generally uniform thickness of a Monocotyledonous stem and the fact that the bark is not usually separable. In Ferns the bast surrounds the wood in each strand, forming ‘concentric’ bundles. So too there are structural peculiarities in the stems of Lycopods and Horsetails, while those of Mosses are, as we would expect, almost wholly cellular without differentiated bundles.

It is not easy to form an accurate conception of the internal structure of stems, but we must bear in mind the following physiological considerations. (1) As the stem is a supporting axis, often bearing heavy weights and resisting great strains, there is usually much *skeletal tissue*—e.g. the bast-fibres, the wood-fibres, and the hard wood which forms the heart of most trees. Schwendener and others have shown that the fibro-vascular bundles are always disposed to mechanical advantage. (2) As the outside of the stem is exposed to the weather and is often subjected to considerable strains, there is usually more or less *protective tissue*—e.g. the tough skin and a layer of cork. (3) As the stem mediates physiologically between the roots and the leaves, it contains *conducting tissue*—(*a*) the young tracheides and wood-vessels by which water and dissolved salts ascend; and (*b*) the sieve-tubes, cambiform cells, and conducting parenchyma by which elaborated materials descend. In the pith, medullary rays, &c. these materials are often stored.

The most practically important stems are those of timber-trees, but their uses are manifold. Thus, the bark of oaks (containing tannin) is used in tanning, and several kinds of bark are used in medicine; the bast-fibres of jute, hemp, &c. are used in making textile fabrics, ropes, and the like; the farinaceous pith of one of the palms is well known as sago, and many other kinds of pith are nutritious; the juices of some stems furnish india-rubber, oil, wine, &c.; the potato is the most important of the edible stem-tubers.

See Bud, Branch, Leaf, Root, Vegetable Physiology; H. Marshall Ward, *The Oak* (‘Modern Science’ series, Lond. 1892), for best English account of internal structure of stem, and *Timber and its Diseases* (‘Nature’ series, Lond. 1889), for theories of ascent of sap; Kerner's *Pflanzenleben* (vol. i., Leip. and Wien, 1889), for adaptations of stems; also text-books of Sachs, Van Tieghem, Asa Gray, Wiesner, and others.

Stencilling, a method of printing letters or designs. The process consists in cutting out the pattern in a thin plate, usually of metal; this is then laid on the surface intended to receive it, and the colour is rubbed into the cut space with a brush, the plate preventing the contact of the colour, except on the space cut out. It is much used for wall and other surface-decoration, as it is a rapid and cheap process.

Stendal, a town of Prussian Saxony, 36 miles by rail N. by E. of Magdeburg, was the former capital of the Altmark, and has a Gothic cathedral (1420-24), a Roland pillar, two old gateways, and a statue of Winckelmann, a native of the place. There are here large railway workshops and some textile industries. Pop. 16,184.

Stendhal. See Beyle; and add two recent French works on him by E. Rod (1891) and (on his diplomatic career) L. Farges (1892).

Stennis. See Stone Circles.

Steno, Nicholas, anatomist and geologist, was born at Copenhagen in 1638. He was brought up a strict Lutheran, and was trained to medicine, winning great fame as an inquirer into the anatomy of the glands, the heart, and the brain. For many years he led a wandering life in Holland, France, Austria, Hungary, Italy, but in 1667 settled in Florence, and was converted to the Roman Catholic faith through the eloquence and earnestness of Bossuet. About this same period he turned his attention to geology. He was the first to point out the true origin of fossil animals; he treated of the structure of the earth's crust, clearly portraying the prevalent stratification of rocks, and discriminating between their volcanic, chemical, and mechanical modes of origination. Soon after settling in Florence he was appointed physician to the Grand-duke Ferdinand II., and later added thereto the office of tutor to the son of Grand-duke Cosimo III. But his conversion gradually drew away his mind from natural science; he became a man of marked piety, was made a bishop, and in 1677 was despatched by the pope to the north of Germany to act as vicar-apostolic of those regions. He died at Schwerin on 25th November 1687. See Professor Hughes in *Nature* for 1882.

Stenography. See SHORTHAND.

Stentor, one of the Greeks before Troy, whose voice was as loud as that of fifty men together.

Stephanotis. See ASCLEPIADACEÆ.

Stephen, saint and protomartyr; see DEACON. His festival falls on December 26.

Stephen, the name of ten popes of the Roman Catholic Church. STEPHEN I. was the successor *of Lucius III., and his pontificate (254–257) is* memorable only for his hotly maintaining against Cyprian that heretics baptised by heretics need not be rebaptised on admission into the orthodox church. A martyr according to tradition, he was canonised, his day falling on August 2.—STEPHEN II. died two days after his election (March 27, 752), hence he is often omitted from the list of popes.—His successor, STEPHEN III., was a native of Rome. When Astolphus, king of the Lombards, threatened Rome, and the Byzantine emperor, Constantine Copronymos, left unheeded his appeals for succour, Stephen turned to Pepin, king of the Franks, who forced Astolphus to withdraw, and gave the pope the exarchate of Ravenna, the real foundation of the temporal power of the papacy. Stephen died in 757.—STEPHEN VII., elected in 896, is infamous from his disinterring the corpse of his penultimate predecessor, Formosus, and throwing it into the Tiber. The year after he himself was strangled in prison.—STEPHEN X. was elected in 1057, under the influence of the celebrated Hildebrand, but died after eight months' rule.

Stephen, king of England (1135–54), was the third son of Stephen, Count of Blois, by Adela, daughter of William the Conqueror, and was therefore nephew of Henry I. and cousin of Matilda, daughter of Henry. He was born in 1105, came over to England at an early age, and became a favourite with his uncle, who gave him the countship of Mortain in Normandy, while he gained that of Boulogne by marriage with its heiress, a niece of the famous Godfrey of Bouillon, and granddaughter of Malcolm and Margaret of Scotland. When his uncle Henry I. resolved to settle the crown on his daughter Matilda, whose first husband was Henry V., emperor of Germany—whence she is often styled the 'Empress Maud'—he held a council in London early in 1127, where Stephen with the rest took the oath of fealty to Maud. A few months later the widowed empress married Geoffrey Plantagenet. On the death of Henry I. (December 1, 1135) Stephen hurried over to England from Normandy, was hailed with enthusiasm by the Londoners and the citizens of Winchester, and was crowned on the 22d of the same month. He promised many reforms, but though really a merciful and generous man he never received, or deserved to receive, confidence from his people. He attempted to strengthen his position by the unpopular policy of bringing into England bands of Fleming mercenaries, and he made enemies as fast as friends by the lavish favours he heaped upon certain of the great lords. King David of Scotland invaded the North on Maud's behalf, but suffered a severe defeat near Northallerton (1138), yet Stephen was not strong enough to do more than compromise with him by way of peace, David's son Henry being allowed to hold all Northumberland save Bamborough and Newcastle as a fief, while David kept Cumberland without homage. The first powerful enemy that the king made within England was Robert, Earl of Gloucester, an illegitimate son of Henry I., who held the strong fortress of Bristol; and next he arrayed against himself the whole power of the clergy by his quarrel with the Justiciar, Roger, bishop of Salisbury, his nephews the bishops of Ely and Lincoln, and his illegitimate son Roger the Chancellor. The realm now fell into sheer anarchy; the barons plundered and burned at their pleasure; 'men said openly that Christ and His saints were asleep.' In 1139 Matilda arrived in England, and in 1141 took *Stephen prisoner at Lincoln.* Matilda was now acknowledged as queen, but her harshness and greed soon disgusted Englishmen. The men of London rose, and she fled to Winchester before them. *On the 1st November 1141 Stephen* obtained his liberty in exchange for the Earl of Gloucester, who had fallen into the hands of his friends at Winchester, and the year 1142 saw him again in the ascendant. Earl Robert died in 1147, and the year after Matilda finally left England. Her son Henry was given the duchy of Normandy in 1149, and next year he became on his father Geoffrey's death Count of Anjou also. He married Eleanor the Duchess of Aquitaine in 1152, and now crossed over to England to pursue his ambition further. The death of his son Eustace took from Stephen all heart for prolonging the struggle, and by the peace of Wallingford and Westminster he agreed to acknowledge Henry as his successor, his continental property being secured to his remaining children, and all the 'adulterine' or unlicensed castles that had sprung up during the civil war, to the number of 1115, to be destroyed. Stephen died at Dover in October 1154.

Stephen, KING. See HUNGARY, Vol. VI. p. 5; POLAND, Vol. VIII. p. 271.

Stephen, JAMES, born at Poole, in Dorsetshire, of an Aberdonian stock, in 1759, was educated at Winchester, and became successively a parliamentary reporter, an official in St Kitts, an advocate in prize cases before the Privy-council, member for Tralee, under-secretary for the colonies, and a master of the Court of Chancery. He died at Bath, 10th October 1832. He was an abolitionist, and author of an able and exhaustive work on *The Slavery of the British West Indies* (1824–30).

HENRY JOHN STEPHEN (1787–1864), his son, was a serjeant-at-law, the author of a *Summary of the Criminal Law* (1834), *New Commentaries on the Laws of England* (1841), &c.—The third son, SIR JAMES STEPHEN (1789–1859), from Trinity Hall, Cambridge, passed in 1813 to Lincoln's Inn, and became counsel to the Colonial Office and Board of Trade, then under-secretary of state for the colonies from 1834 to 1847, when he was knighted. From 1849 he was regius professor of Modern History at Cambridge. See the Memoir prefixed to the 4th edition of his *Essays in Ecclesiastical History* (1849), another well-known work by him being *Lectures on the History of France* (1851).—The youngest son, SIR GEORGE STEPHEN (1794–1879), was successively a solicitor and barrister, was knighted in 1837 for his services in the reform of the poor-laws, imprisonment for debt, and the police force; in 1855 emigrated to Victoria; and like his father wrote on the slavery question.

SIR JAMES FITZJAMES STEPHEN, son of Sir James Stephen, was born at Kensington, 3d March 1829, and educated at Eton, King's College, London, and Trinity College, Cambridge. Taking his B.A. (1852), and called to the bar at the Inner Temple (1854), he travelled the Midland Circuit, and became recorder of Newark-on-Trent (1859–69), a Q.C. (1868), legal member of the Viceroy of India's Council (1869-72), professor of Common Law at the Inns of Court (1875-79), a K.C.S.I. (1877), and judge of the High Court of Justice (1879-91), on his retirement being created a baronet. The Indian Evidence Act was due to him; and among his works are a *General View of the Criminal Law of England* (1863); *Liberty, Equality, and Fraternity* (1873); *Digest of the Law of Evidence* (1876); *Digest of the Criminal Law* (1877); *History of the Criminal Law of England* (1883); *Story of Nuncomar* (1885); and *Horæ Sabbaticæ: Essays from the Saturday Review* (1892). He unsuccessfully contested Harwich (1865) and Dundee (1873) as a moderate Liberal.—His younger brother, LESLIE STEPHEN, born at Kensington, 28th November 1832, was educated at Eton, King's College, London, and Trinity Hall, Cambridge, where, having graduated in 1854, he was for a time a fellow and tutor. Then relinquishing his orders and removing to London, he became editor of the *Cornhill* (1871-82), and of the first twenty-six volumes of the great *Dictionary of National Biography* (1885-91, from 1890 conjointly with Mr Sidney Lee, his successor). His works include *The Playground of Europe* (1871; he was president for a while of the Alpine Club); the delightful *Hours in a Library* (3 vols. 1874-79); *History of English Thought in the Eighteenth Century* (1876); *Johnson* (1878), *Pope* (1880), and *Swift* (1882) in the 'English Men of Letters' series; *Science of Ethics* (1882); and *Life of Henry Fawcett* (1885).

Stephens, the English equivalent of the French family name of ESTIENNE or ETIENNE, celebrated as printers and publishers. The first of the family (descended from a line of Provençal nobles) to embark in this business was HENRY STEPHENS (*c.* 1460-1520), who settled in Paris about 1500. His business was taken up in 1526 by his second son ROBERT (b. 1503), having in the interval been managed by his step-father. Robert specially distinguished himself by the excellence of his workmanship, and was in 1539 and 1540 appointed printer to the king in Latin, Greek, and Hebrew. Early in life he became a convert to the doctrines of the Reformation; and on more than one occasion he got into difficulties with the theological authorities of the university of Paris for introducing editorial changes in the text of the Bibles and Testaments he printed. In 1550 indeed he found it prudent to retire to Geneva. There he remained until his death, on 7th September 1559, and published several of Calvin's works. Robert Stephens was a scholar as well as a printer; he published and printed in 1532 a Latin dictionary (*Thesaurus Linguæ Latinæ*) which remained a standard work down to the middle of the 18th century. Amongst his editions of the Holy Scriptures the Latin New Testament of 1523, the Latin Bible (folio) of 1528, and the Greek New Testament (folio; see BIBLE, Vol. II. p. 126) of 1550 deserve special mention. Being a lover of the New Learning he also printed several of the classic authors, numerous Latin grammars, and similar books. Robert's brother CHARLES (1304-64), who graduated in medicine and practised in Paris, took charge of his brother's business when he withdrew to Geneva, and wrote and printed himself an encyclopædic work (*Dictionarium Historicum ac Poeticum*, 1553), a collection of ancient treatises on agriculture (*Prædium Rusticum*, 1554), and other books. Robert's eldest son HENRY (born at Paris in 1528) worthily sustained the reputation of the family. He received an excellent education, and became celebrated for his knowledge of Greek. Both before and after he settled down at Geneva (in 1551) he travelled in Italy, England, and the Netherlands, collating MSS. (mostly Greek), and consorting with scholars. In 1556 he set up a press of his own in Geneva, and issued from it a great number of the ancient Greek authors, including some twenty 'first editions.' His greatest achievement as a scholar was a Greek dictionary entitled *Thesaurus Græcæ Linguæ* (5 vols. folio, 1572), on which he spent nearly all his fortune. In his editions of classic authors he indulged in many textual emendations, most of them based on MS. authority, but some purely conjectural. From about the year 1578 he led a very restless and wandering life, and his business was greatly neglected, till at length he died at Lyons early in 1598. He also wrote his mother-tongue with force and elegance, his most remarkable production in it being the semi-satirical *Apologie pour Hérodote* (1566). The traditions of the family were kept up by PAUL (1566-1627), the son of Henry (II.) Stephens, who printed valuable editions of Euripides (1602) and Sophocles (1603); and by Paul's son ANTOINE (1592-1674), who became king's printer at Paris, and amongst other books printed the Septuagint.

See Greswell's *View of the Early Parisian Greek Press* (1833); French works by Renouard (2d ed. 1843) and Bernard (1856); and Mark Pattison's posthumous *Essays* (1889).

Stephens, ALEXANDER HAMILTON, an American statesman, was born in Georgia in 1812, admitted to the bar in 1834, and elected by the Whigs in 1843 to congress, where he sat till 1859. He advocated the annexation of Texas as early as 1838, and in 1854 defended the Kansas-Nebraska act. He at first opposed secession, but in 1861 became vice-president of the Confederacy, and in 1865 was imprisoned for five months. He sat in congress again from 1874 to 1882, was elected governor of Georgia in 1882, and died 4th March 1883. His *War between the States* appeared in 1867-70.

Stephens, GEORGE, archæologist, was born in Liverpool, December 13, 1813, and was educated in University College, London. He settled early at Stockholm, and was appointed in 1851 lector, later professor, of English in the university of Copenhagen. His works are numerous and learned, the most important his magnificent *Old Northern Runic Monuments of Scandinavia and England* (3 vols. 1866-68-84), and its abridgment, containing, however, all the engravings and translations (1884). Other works are on the Ruthwell Cross (1868), on Bugge's Studies in Northern Mythology (1883), and his early translation into English of Tegner's *Frithiof* (Stockholm, 1841).

Stephens, JAMES, Fenian, was born at Kilkenny in 1824, son of an auctioneer's clerk with more of Saxon than of Celtic blood. He had a good education, took early to mathematics, and at twenty obtained an appointment during the making of the Limerick and Waterford Railway. He next went to Dublin, and soon became one of the most active agents of the Young Ireland party. He was slightly wounded at the miserable scuffle of Ballingarry (29th June 1848), skulked for three months thereafter among the mountains from Tipperary to Kerry, and then sailed from Cork to France disguised as a lady's servant. For some years he lived mainly at Paris, where he obtained an insight into the working of continental secret societies, and in 1853 journeyed over Ireland making himself acquainted with its condition and preparing the soil for the Fenian conspiracy. As its 'Head Centre' he exercised an enormous and despotic influence, and throughout showed remarkable dexterity in the disguises and characters he assumed on his visits to all parts of Ireland. He visited America early in 1864 to attempt to overthrow the rival schemes formed there by patriots, and was arrested in Dublin on the 10th November of the same year. Fourteen days later he made his escape from Richmond Bridewell in a manner so suspicious that many have looked for the explanation rather to government connivance than to the treachery of officials. He found his way to New York, where he was formally deposed by the Fenians. He sank into obscurity, and was even allowed to return to Ireland in 1891. See Fenians.

Stephenson, George, the father of the locomotive, was the son of Robert Stephenson, who again was the son of a Border shepherd in Oxnam parish, Roxburghshire, and had crossed the Cheviots in search of work at the Northumbrian coal-mines. He was born at Wylam, 8 miles from Newcastle, on the 9th of June 1781, in circumstances of great poverty, his father having to maintain a family of six children on twelve shillings a week, earned by tending a colliery-engine. George's first employment was herding cows at twopence a day, from which he was promoted to hoeing turnips at fourpence; subsequently he was appointed fireman at Midmill Colliery, and at fifteen we find him at Throckley Bridge, rejoicing in a salary of twelve shillings a week. The early life of Stephenson presents a record of determined purpose, industry, and sagacity. Out of his humble gains he contrived to pay fourpence a week for lessons in reading, writing, and arithmetic, which were conned over at night, and mastered by the light of his engine-fire. As fireman he applied himself to diligent study of the steam engine, taking his machine to pieces during his leisure hours, and thus gaining a thorough practical knowledge of it. At Black Callerton Colliery in 1801, by dint of mending shoes and cleaning watches, in addition to his regular employment, Stephenson contrived to save his first guinea. At twenty-one he had saved enough to furnish a cottage in a humble way, and on 28th November 1802, he was married to Fanny Henderson, who died in 1806, while her husband was brakesman at Killingworth Colliery. In 1815 the invention of a colliery safety lamp, the 'Geordie,' brought his name before the public, and led to a long controversy with the supporters of Davy's Safety-lamp (q.v.). He received a public testimonial of £1000 for his discovery. In 1812 he became engine-wright at Killingworth Colliery, and it was here, by Lord Ravensworth's permission (1814), that he constructed his first locomotive, 'My Lord,' for the colliery tram-roads. At first it was not very efficient; but subsequently the grand improvement of the 'steam-blast' carried his experiment to a triumphant issue (see Railways). Further improvements followed, and in 1821 Stephenson was appointed engineer for the construction of the Stockton and Darlington Railway. In 1820 Stephenson married his second wife, Elizabeth Hindmarsh, the daughter of a farmer.

The rapid growth of the trade of South Lancashire, together with the unpopular management of the Bridgewater Canal, gave rise in 1821 to the project of a railway between Liverpool and Manchester. When the bill ultimately passed, on 16th March 1826, Stephenson was appointed principal engineer, with a salary of £1000 a year. After inconceivable difficulties the line was completed in 1829. There then ensued the memorable competition of engines, resulting in the complete triumph of Stephenson's 'Rocket' (see fig. in Vol. VIII. p. 554), which, to the astonishment of every one except himself, was found capable of travelling at the till then undreamt-of rate of 35 miles an hour. 'Now,' exclaimed one of the directors, 'has George Stephenson at last delivered himself.' While occupied in carrying out the vast system of railway which soon overspread the country Stephenson's home was at Alton Grange, near Leicester; but of it he saw little, as he was often travelling on business for weeks at a time. During the three years ending 1837 he was principal engineer on the North Midland, York and North Midland, Manchester and Leeds, Birmingham and Derby, and Sheffield and Rotherham Railways; in 1836 alone 214 miles of railway were put under his direction, involving a capital of five millions; and he would sometimes dictate reports and letters for twelve continuous hours. But in the midst of his immense business his heart remained as youthful as ever. In spring he would snatch a day for bird's-nesting or gardening, in autumn nutting was still a favourite recreation; and we find him writing to his son a touching account of a pair of robins. Strong as he had shown himself when the world was all against him, he was not less so in the midst of his success. During the railway mania his offices in London were crowded every day with men of every rank and condition, eager to strengthen their prospectuses by the weight of his name. Where he disapproved—and at this time he almost always did disapprove—he invariably declined, though by acceding he might have made enormous gain; but to make money without labour or honour had no charm for Stephenson. In the autumn of 1845 he visited Belgium and Spain. On his way home he was seized with pleurisy, from which attack he seems never to have thoroughly recovered. He occupied his later years in the quiet pursuits of a country gentleman, growing fruit and indulging his love of nature. He died at his country-seat of Tapton, near Chesterfield, on 12th August 1848. In his prime Stephenson was strong and full of elastic muscular vigour, and fond of feats of strength. He read little, as his youth and manhood had been spent in hard work; and most of his letters were dictated. But he enjoyed conversation, from which most of his imparted information was derived. The leading feature of his mind was honesty of purpose, and determination in carrying it out. 'I have fought for the locomotive single-handed for nearly twenty years,' he says; 'I put up with every rebuff, determined not to be put down.' Towards trickery and affectation he never concealed his contempt, while honest merit never appealed to his liberality in vain.

See Smiles's *Story of the Life of George Stephenson* (1857; new ed. 1873); and vol. v. of his *Lives of Engineers* (George and Robert Stephenson; new ed. 1874).

Stephenson, Robert, only son of George Stephenson, by his first wife, was born at Willington Quay on 16th October 1803. When a boy he attended a school in Newcastle; in 1819 he was apprenticed to a coalviewer at Killingworth. In 1822 his father's improving circumstances enabled him to send Robert to the university of Edinburgh, where he remained six months, and made excellent use of his time. In 1823 we find him assisting his father in the survey for the Stockton and Darlington Railway. Subsequently he took an active part in the locomotive engine-works started by his father at Newcastle. In June 1824 he went to Colombia, in South America, on an engineering appointment, but returned at the end of three years. He then assumed the management of the Newcastle business. During the discussion as to the power to be employed on the Liverpool and Manchester line, he was in constant communication with his father, to whom his quick perception and rapid judgment were of great assistance. The result was the successful construction of the 'Rocket.' Shortly after the completion of this line he was appointed engineer of the Leicester and Swannington Railway. Subsequently he was appointed joint-engineer, along with his father, of the London and Birmingham line, the execution of which immense work was ultimately almost wholly entrusted to him. In 1829 he married Frances, daughter of John Sanderson, merchant in London. She died in 1842 without issue. The London and Birmingham line was completed in such a manner as to raise Stephenson to the very highest rank in his profession. Amongst his great achievements were the Britannia and Conway Tubular Bridges, the Victoria Bridge across the St Lawrence at Montreal, the two bridges across the Nile at Damietta, the Royal Border Bridge, Berwick, and the High Level Bridge, Newcastle, several of which are described at BRIDGE, Vol. II. pp. 440-1. In 1847 he was returned to the House of Commons as member for Whitby. He was the recipient of many honours from abroad, and was consulted about foreign railways. He died on 12th October 1859, and was buried in Westminster Abbey. Robert Stephenson inherited the kindly spirit and benevolent disposition of his father, to whom he was ever ready to attribute the chief merit of his own achievements. 'It was his thorough training,' he once said, 'his example, and his character which made me the man I am.'

See Smiles's *Story of the Life of George Stephenson* (1857) and *Lives of the Engineers*, vol. v., and J. C. Jeaffreson's *Life of Robert Stephenson* (2 vols. 1864).

Stepney. See LONDON, Vol. VI. p. 703.

Stepniak, the *nom de guerre* of an exiled leader of the Russian revolutionary party, was born in 1852 of a Little Russian family belonging to the lesser nobility, and was trained for a military career. He for some time held a commission in the artillery, which he resigned; and having become obnoxious to the government as an apostle of freedom, he was arrested and subsequently kept under such surveillance as rendered it necessary for him to leave Russia and settle (1876) in Geneva, and subsequently (1885) in London. He has lectured and written for the magazines in England and America, but is best known as author of *La Russia Sotterranea* (Milan, 1881; Eng. trans. *Underground Russia*, 1883), a series of brilliant studies and sketches of the Nihilist movement and its leaders; of *Russia under the Tzars* (Eng. trans. 1885), a terrible indictment of the governmental régime in church and state; and of *The Career of a Nihilist*, a novel (1889). He is a prominent member of the English 'Society of Friends of Russian Freedom.'

Steppes, the distinctive name of the broad plains of southern Russia and western Siberia. See DESERT.

Sterculiaceæ, a family of Dicotyledons, closely allied to Malvaceæ and Byttneriaceæ; with these and the Tiliaceæ they form the natural order of Columniferæ. The family consists of large trees and shrubs, natives of warm climates. About 130 species are known. The flowers of some are irregular; and in some they are hermaphrodite, in others unisexual. Many species, particularly of the sub-order Bombaceæ, are trees of gigantic size, amongst which is the Baobab (q.v.) or *Adansonia digitata*. The bark of some species is very fibrous, so that it is made into ropes and coarse cloth. The light wood of *Ochroma lagopus* is used in the West Indies instead of cork. *Sterculia fœtida*, an Indian tree, with excessively fetid flowers, has pale wood, which is very durable, and susceptible of a high polish. Spars of this wood are called *Poon Spars*. The seeds of some species, as of the Silk-cotton (q.v.) trees, are surrounded with silky hairs. The seeds of all the species are oleaginous; those of some are eatable, as those of the Chicha (*Sterculia chicha* and *S. lasiantha*) of Brazil, which are about the size of a pigeon's egg, and have a pleasant flavour. They are roasted before being eaten. The Kola Nut (q.v.) of Africa is the seed of a Sterculia. The whole order agrees with Malvaceæ in possessing mucilaginous and demulcent properties. The Gum Tragacanth (see GUM) of Senegal and Sierra Leone is produced by *Sterculia tragacantha*. The Durian (q.v.) is the fruit of a tree of this order.

Stere (Gr. *stereos*, 'solid'), the name given to the unit of cubic measure in the French metrical system. It is a cubic *Mètre* (q.v.), and equivalent to 35·3156 English cubic feet. The *decastère* is equal to 10 steres, and the *decistère* to the tenth part of a stere. This measure is much used for wood, especially firewood.

Stereoscope (Gr. *stereos*, 'solid,' and *skopein*, 'to see'). Each eye of an observer forms its own retinal image of visible objects. These two images, being taken from slightly different points of view, are slightly different from one another, as may be seen by looking at near objects with each eye alternately; and they are the more so the nearer or the narrower the objects are. These two retinal images are blended by a process of interpretation of sensation, which interpretation is based on experience, into a mental image of the object seen as a solid object possessing three dimensions. Professor (afterwards Sir Charles) Wheatstone first pointed this out in 1838, and set himself the question, 'What would be the visual effect of simultaneously presenting to each eye instead of the object itself its projection on a plane surface as it appears to that eye?' He tried the experiment with drawings of cubes, &c., and found that when one eye was made to look at each drawing the two images blended into one which appeared to stand out in relief. Photography supplies more accurate representations of views from two points of view than the artist's eye and hand can supply; and if a view be taken by two lenses upon different parts of a single sensitive plate the print from the negative must be divided into two and the two pictures transposed and mounted. If this transposition be neglected the effect is *pseudoscopic*—i.e. instead of objects standing out in relief they stand back as if their more prominent surfaces were the walls of cavities. The stereoscope is essentially an instrument in which each picture is examined by a separate lens, and the two lenses are inclined so as to shift the images towards one another and thus to ensure or to facilitate the blending of the two images into one, besides which the lenses act as magnifying glasses. The two lenses must be equal. This may be ensured by using instead of whole lenses two halves of a single lens, the straight edges of which halves must be fixed parallel to one another.

Stereotyping (Gr. *stereos*, 'solid') is the art of fabricating solid casts in type-metal from pages of movable types. Unless when the number required of any printed matter is very small, the actual printing is very seldom executed directly from the types (see PRINTING). When the pages are all corrected and ready for the press casts are taken from them either in type-metal (stereotypes) or in copper (electrotypes). The latter method, being sharper and much more durable, is generally used when large numbers are to be printed, and will be found described in the article ELECTRO-METALLURGY.

Stereotyping being much cheaper, and quite suitable where moderately large numbers are required, has also, in the papier-maché process, the advantage that it can be executed in a very short time—an important matter in connection with newspapers. It was invented by William Ged (q.v.), a goldsmith in Edinburgh, about the year 1725. His process is as follows: after slightly oiling the surface of the types with a soft brush, stucco mixed to the consistency of thick cream is poured over them and allowed to 'set;' the stucco, when taken off and baked in an oven till quite hard, forms a perfect matrix from which a cast in type metal (see TYPE) is taken by means of a hollow casting-box which dips the mould into the molten metal. The cast, which should be a perfect fac-simile of the types, is finally trimmed, planed on the back down to the required thickness (about $\frac{1}{6}$ inch), and carefully sized to fit the blocks on which it is to be printed. This process was universally employed for all purposes till it began to be superseded by the *papier-maché* process, invented by Genoux (1829), and introduced into England from the Continent. Its advantages, in cheapness and rapidity, were at once apparent, and now Ged's process is nearly if not quite extinct. The process is as follows: several plies of soft thin paper, very carefully pasted together, are placed in a wet state on the face of the types, beaten in with a hard brush, and impressed as deeply as possible into all the interstices. The hollows on the outside of the paper are filled up with pipeclay or similar material to give solidity to the mould, and a strong piece of brown paper pasted over all. It is then dried on a hot plate till hard enough to be lifted off the types. It is next put into a flat casting-box, the sides of which are, when closed, just far enough apart to allow the cast to be of the required thickness. The metal must be poured in hot enough to run properly, but not hot enough to burn the paper. The cast is then trimmed and made ready for the printing-machine as in Ged's process. Any accidentally bad letters can be replaced by cutting a hole in the plate, and inserting and soldering in a type. Whole lines or sentences can also be altered, the required new pieces being cast separately and soldered into the plate. The papier-maché mould is not destroyed by the casting like the stucco matrix, but can be kept, and, if carefully used, almost any number of casts may be made from it.

It is a modification of this process which has made the printing of newspapers on the rotary printing-machine successful (see PRINTING). In this process, where the stereotype plates are required to be fitted round a cylinder, and great rapidity is necessary, the following changes are made on the method already described. The paper, instead of being beat into the type with a brush, is pressed in with a soft roller, and is then rapidly dried by means of hot blankets in a hot press. When ready the mould is bent inside a cylindrical casting-box, the core of which is exactly of the same diameter as the printing cylinder. The cast when taken out consequently fits the machine exactly. So complete are the stereotyping arrangements in the larger newspaper offices that duplicate casts of a page of the paper can be prepared in ten or twelve minutes. See F. J. F. Wilson, *Stereotyping and Electrotyping* (3d ed. 1887).

Sterility, barrenness in regard to reproduction of the species, is a term applied both to plants and animals, and may be due to external conditions, functional disorder, organic defects, or, in human beings, the results of surgical treatment. See FLOWERS (FERTILISATION OF), REPRODUCTION, EMBRYOLOGY, SEX, HYBRID, PUBERTY, &c. Impotency renders a marriage void; sterility in no way invalidates the marriage tie. As is well known, it frequently happens that children are born to parents who have been childless for many years. See works cited at OBSTETRICS and MEDICAL JURISPRUDENCE; Dr S. W. Gross, *On Impotence and Sterility of Males* (1881); Dr Matthews Duncan, *On Sterility in Women* (1884).

Sterlet. See STURGEON.

Sterling, *originally* a substantive, 'a coin of true weight,' as applied at first to the English penny, then to all current coin. Skeat accepts the old and often doubted etymology that the name is derived from the Hanse merchants or *Easterlings* (i.e. 'men from the east'), who had many privileges in England in the 13th century, including probably that of coining money (see Vol. V. p. 541). The adjective is now used of all the money of the United Kingdom, and has long been a synonym for pure and genuine.

Sterling, a city of Illinois, on Rock River (here crossed by two bridges, one of iron, 1100 feet long), 109 miles W. of Chicago by rail. A large dam supplies water-power to most of the fifty factories, which produce farming implements, barbed wire, pumps, windmills, wagons, paper, flour, &c.; and there are five foundries. Pop. (1890) 5824.

Sterling, JOHN, was born at Kames Castle in Bute, 20th July 1806, where his father, Captain Edward Sterling (1773-1847), was then making trial of farming. Ill-success drove him to Llanbethian, near Cowbridge, Glamorganshire, in 1809, thence to Paris, and finally to London, where he became one of the chief oracles of the *Times*. Of his seven children, John and an elder brother alone lived to grow up. John was educated at private schools, at sixteen went to Glasgow University, and at nineteen entered Trinity College, Cambridge, where he had Julius Hare as his tutor. Impulsive, quick-witted, 'able to argue with four or five at once,' he was recognised as the most brilliant member of the famous debating society—the Union—members of which were Maurice, John Kemble, Spedding, Venables, Charles Buller, and Richard M. Milnes. After a year Sterling followed Maurice to Trinity Hall, but left Cambridge without a degree in 1827. He first thought of law, but soon became busy on the *Athenæum*, which had not yet begun to flourish. A Liberal in thought and in politics, he came under the influence of Coleridge, and formed a fast friendship with General Torrijos, chief of a group of Spanish exiles. Indeed his own uncertain health and his becoming at the hour of parting engaged to Miss Barton alone prevented his sailing on that crazy expedition which came to its inevitable close in the execution of Torrijos and Sterling's cousin Boyd at Malaga—a tragedy which haunted Sterling with a lasting horror. He married in November 1830, but soon after fell dangerously ill, and spent fifteen months in the island of St Vincent, returning in August 1832. In June of next year he met Hare at Bonn, and partly through his influence took orders, and served with characteristic zeal as Hare's curate at Hurstmonceaux for eight months. His health again giving way, he resigned, and though he sometimes for some time after, as Carlyle tells us, took duty for a friend in London, he never advanced to priest's orders; indeed, the divergence between his opinions and the church's soon widened beyond even the Coleridgean capability of accommodation. Carlyle first met him in February 1835, and his friendship with Maurice was knit still faster by the latter's marriage to Sterling's sister-in-law. He wrote for *Blackwood* and Mill's review—the *Westminster*, busied himself with projects for tragedies, one of which, *Strafford*, saw the light for a little in 1843, and wrote poems, one of which, *The Election*, was published in 1841. In August 1838 he formed the club first called the Anonymous, then the Sterling Club, among whose members were Carlyle, Allan Cunningham, G. C. Lewis, Malden, Mill, Milnes, Spedding, Tennyson, Thirlwall, W. H. Thompson, and Venables. His winters were spent abroad at Bordeaux, Madeira, or in Italy, in the vain hope of staving off his inevitable doom. In England he lived in turn at Clifton, Falmouth, and Ventnor, and here he died, 18th September 1843.

Julius Hare edited Sterling's *Essays and Tales* (2 vols. 1848) with a memoir, which seemed to Carlyle so incomplete, as dwelling too exclusively on his ecclesiastical side—a brief accident in his career—that he himself determined to write his life, to give a faithful picture of his friend. The result was a masterpiece of biography which will keep the name of John Sterling from ever being forgotten.

Stern, Daniel. See Agoult.

Sternberg, a town of Austria, 12 miles by rail N. of Olmütz, with cotton and linen manufactures. Pop. 14,243.

Sterne, Laurence, one of the greatest of English humorists, was born at Clonmel in Ireland, on the 24th of December 1713. His father, Roger Sterne, at that time an ensign in the 34th or Chudleigh's regiment of foot, was the grandson of an archbishop of York who had played an active part as a Cavalier ecclesiastic in the troubles of the previous century. Of his mother we know only that she was the daughter of a 'noted sutler' of the name of Nuttle, and the widow of a soldier, probably a comrade of her second husband. To Roger Sterne she bore seven children, of whom, however, but three survived the period of infancy. The family, continually recruited by births and reduced by deaths, accompanied their parents in the ceaseless wanderings necessitated by the father's military duties; and it was not till Laurence was eleven years old that it was found possible, or at least convenient, to give him any systematic education. He was then sent to Halifax grammar-school, where he remained for over seven years, and whence he was by the assistance of his kinsman, Simon Sterne of Elvington, sent to Jesus College, Cambridge. Here he obtained a sizarship, and in 1736, after taking his B.A. degree, he quitted Cambridge for York, where his father's brother, Dr Jacques Sterne, held, together with a goodly number of ecclesiastical offices, the archdeaconry of the diocese. Through this uncle's influence Laurence, who had been ordained three months after taking his degree, and who took priest's orders in 1738, was presented to the living of Sutton-in-the-Forest, and then or immediately afterwards appointed a prebendary of York.

Three years later, in 1741, he married Miss Elizabeth Lumley, by whom he had one daughter, Lydia, born in 1745, to whom he was all his life tenderly attached, and who published an edition of his Letters after his death. Of his life in his Yorkshire parish during the next nineteen years little or nothing is known, except that at some time, probably near the end of this period, a quarrel took place between him and his uncle, because (to quote the former's account of it) 'I would not write party-paragraphs in the newspapers; though he was a party man I was not, and detested such dirty work, thinking it beneath me.' In 1759 he wrote the first two volumes of the work which was destined to make him famous, *The Life and Opinions of Tristram Shandy*, and which, after being first published at York in the autumn of that year by a local bookseller, was brought to London by its author in 1760, and there published anew. Its success was immediate and signal, and Sterne at once became a 'lion' of the fashionable world. The first edition of the book was exhausted in three months. In April Dodsley brought out a second, and this was shortly afterwards followed somewhat incongruously by a volume of the *Sermons* of the 'Rev. Mr Yorick.' By the end of the year vols. iii. and iv. of *Tristram Shandy*, for which Dodsley had given £380 in advance, were already in the press, and in January 1761 they made their appearance to receive from the town as heartily amused a welcome as their two predecessors.

Meanwhile Sterne, who had in the previous year been presented by one of his new friends of rank, Lord Falconberg, to the living of Coxwold, had transferred his residence to the parsonage of that place, which was thenceforth to be his home; and throughout the greater part of 1761 he was busy there upon the fifth and sixth volumes of his novel. They were published in December, and three weeks later Sterne, whose health, never robust, was already beginning to fail, left England for France, where he was received with high honours by the literary society of the time, and where he prolonged his stay until the summer of 1764. In January 1765 vols. vii. and viii. of *Tristram Shandy* were given to the world, and met with a more favourable reception than the two preceding volumes, the public interest in which had slightly flagged. They were followed by the publication of a second series of *Sermons* of a far more unclerical character than their predecessors, and, indeed, abounding in quaint touches of their author's peculiar humour. The autumn and winter of 1765 were spent in a tour through France and Italy, which supplied the material of the work to which, in the former of those countries, he still owes his fame. The summer of the following year saw him at work again at Coxwold on the ninth and last volume of *Tristram Shandy*, which appeared in January 1767. The rest of that year was occupied in the preparation of the first two volumes of *The Sentimental Journey through France and Italy*, and in the last days of February 1768 they were published. Their author's health, however, was now completely wrecked; the pulmonary malady from which he had long suffered advanced with rapid strides; and, attacked by pleurisy in the early days of March, he breathed his last in his London lodgings on the 18th of that month. His funeral, which was attended by only two mourners, one of whom was his publisher, took place four days after, at the Bayswater burying ground of the parish of St George's, Hanover Square. A grim legend later obtained currency to the effect that two days after their interment Sterne's remains were stolen by body-snatchers and disposed of to the professor of Anatomy at Cambridge, by whom, a friend of the deceased, they were actually recognised on the dissecting-table. There seems, however, to be no other warrant for this ghastly story than is to be found in the fact, attested by the records of contemporary journals, that similar desecrations of this particular graveyard had about that time been common. The truth, however, as to the exact spot of Sterne's sepulture cannot now be ascertained. A stone erected many years later with an inscription recording (inaccurately) the date of his death, declares his body to be lying 'near to this place,' but that is all.

His position in English literature is almost in like case; for there is much the same difficulty in assigning their true place to his literary remains. It is, on the one hand, undeniable that there have been few writers of any age or country who have displayed such mastery over every form of humour, from the lowest to the highest, as was exercised from his very first entrance into the field of authorship by this Yorkshire clergyman who never published a line till he was close upon fifty, and who had somehow qualified himself for immediate and enthusiastic reception in the world of letters by a twenty-years' sojourn in a country parsonage. Yet, on the other hand, the imperfections of his art, and that in point not only of execution, but also of artistic conception and spirit, is impossible to overlook. The wild eccentricity of his manner and arrangement, though it is of course a deliberate and, as a rule, it must be admitted, a highly successful bid for the laughter of the reader, was also to some extent the convenient cloak of a singularly slipshod literary style. His indecencies, if less gross than those of Swift or Rabelais, are by reason of their pruriency far more offensive. His passages of pathos, sometimes genuine and deeply moving, too often take the form of an artificial and overstrained sentimentalism, and degenerate from the affecting into the affected. His literary conscience had more than the laxity of his time, and, as a later critic of much learning and acumen, Dr Ferriar, showed, he was unscrupulous in his unacknowledged borrowings from the writings of other men. Nevertheless he is, and deserves to be, a classic of English prose fiction. The extravagant Rabelaisian drollery that revels through the pages of *Tristram Shandy*, the marvellous keenness of eye, the inimitable delicacy of touch to which we owe the exquisite vignettes of the *Sentimental Journey*, might not of themselves have secured that place for Sterne; but it is for ever secured to him in right of that combination of subjective and personal with objective and dramatic humour in which perhaps he has never been excelled by any one save the creator of Falstaff. In Mr Shandy and his wife, in Corporal Trim, in Yorick, and above all in that masterpiece of truthful, subtle, tenderly humorous portraiture, 'My Uncle Toby,' Sterne has created imperishable types of character, and made their immortality his own.

See John Ferriar, *Illustrations of Sterne* (2 vols. Warrington, 1812); *Life*, by Percy Fitzgerald (2 vols. 1864); the present writer's *Sterne*, in the 'English Men of Letters' series (1882); *Autobiographical Fragment* (quoted in Scott's and other memoirs).

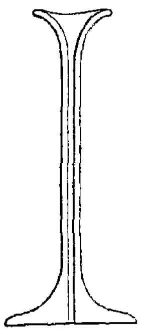
Sternhold, Thomas, one of the authors of the English version of psalms formerly attached to the Book of Common Prayer, was born about 1500 near Blakeney in Gloucestershire, according to Fuller and Wood, in Hampshire. He was Groom of the Robes to Henry VIII. and Edward VI., and died in August 1549. The first edition (undated) contains only nineteen psalms; the second (1549), thirty-seven. A third edition, by Whitchurch (1551), contains seven more by J. H. [John Hopkins], probably a native of Awre in Gloucestershire, who died as rector of Great Waldingfield, Suffolk, in 1570; and the complete psalms appeared in 1562, and for nearly two centuries after formed almost the whole hymnody of the Church of England. When the rival version of Tate and Brady appeared (1696) it came to be known distinctively as the 'Old Version.' Of the complete psalter of 1562, forty psalms bear the name of Sternhold, and sixty that of Hopkins. The rest were the work of William Whittingham (d. 1579), husband of Calvin's sister and Dean of Durham; Thomas Norton; William Kethe, most probably author of Psalm c. (not, however, printed here till 1565, though already in Daye's Psalter, 1560-61, and the Anglo-Genevan, 1561); J. Pullain; J. Marckant; and Archdeacon Wisedome of Ely (d. 1568). Sternhold and Hopkins' psalms are very faithful, but somewhat coarse and homely in phraseology. As Fuller well said, its authors' 'piety was better than their poetry, and they had drunk more of Jordan than of Helicon.' See J. Julian's magistral *Dict. of Hymnology* (1892).

Sternum. See Skeleton, Ribs, Bird.

Sternutatories. See Sneezing.

Stesichorus, greatest of the old Dorian lyrists, and as such called the 'lyric Homer,' was born at Himera in Sicily about 630 B.C., and died in Catania in 556. He dealt largely with epic subjects in his lyrical measures, such as the sieges of Troy and of Thebes, and was said to have been struck blind for slandering Helen. Only some thirty short fragments of his works remain, to be found in Schneidewin's *Delectus* and Bergk's *Poetæ Lyrici.*

Stethoscope (Gr. *stethos*, 'the chest,' and *skopeō*, 'I look into'), an instrument invented by Laennec (q.v.) for examining the sounds of the chest. Its simplest form will be best understood by the figure, which represents the section reduced to half the natural diameter, or one-eighth of the actual size. The upper part is the chest end, the lower the ear-piece. The latter is often made in a separate piece, for the sake of greater portability. The main object of the stethoscope being to circumscribe and localise the sounds which it transmits, the chest end should be small, in order to determine the exact seat of the greatest intensity of sound. To ascertain this, the instrument should be moved right and left, up and down, till its end is on the exact spot from which the abnormal sound for which we are searching—or, it may be, the absence of sound—proceeds. It may be made of wood, metal, or celluloid; it is usually made hollow as represented in the figure, but this is not necessary, as the sound is well conducted by the stem itself. But besides these rigid instruments flexible ones are largely used, particularly the *binaural* stethoscopes, which have an ear piece for each of the examiner's ears. In these the ear-pieces and chest-piece are united by hollow tubes of india-rubber, felt, &c., whose mobility permits of much more ready adaptation to different parts and different positions of the patient's chest. The various sounds heard through the stethoscope are very important in the recognition of many diseases of the heart and lungs.



Stethoscope.

Stettin, the capital of the Prussian province of Pomerania, and one of the busiest ports on the southern side of the Baltic, stands on both banks of the Oder, 30 miles from the Baltic and 60 miles by rail (120 by river and canal) NE. of Berlin. The more important of the public buildings are the Gothic church of St Peter (founded 1124), the large church of St James (14th century), the royal palace (1575), two ornamental arches, a hospital, town-house, theatre, &c. The strong fortifications were only removed in 1874; since then the ground on which they stood has been rapidly built over, so that Stettin now forms virtually one large town with Bredow (pop. 13,713), Grabow (15,644), and Züllchow (6711). Excluding these places, Stettin has a pop. of (1871) 76,154; (1890) 116,139. It is the seat of considerable industrial activity, chiefly in connection with shipbuilding, cement, sugar, paper, spirits, soap and candles, matches, clothing, oil-refining, chicory, chemicals, flour, sewing-machines, bricks, machinery. The river has a depth of 17 to 21 feet opposite the wharves. The port is entered by an average of 3640 vessels of 1,257,600 tons a year (466 vessels of 356,800 tons British), importing principally petroleum and other oils (annual value £1,100,000), rye, coffee, herrings, chemicals, groceries, cotton, seeds, iron, cement, timber, coal, oats, spirits, wool, hides, to the total value of £7,615,000 annually. The exports reach an average of £7,432,700, and embrace sugar (£1,298,000), metals (£936,000), cereals, spirits, seeds, timber, cement, and herrings. Great Britain supplies from two to three millions sterling of the imports, and takes about two millions of the exports. Stettin was the seat of a princely dynasty, 1107 to 1637; was occupied by Sweden, 1648-1720; by the French, 1806-13. See works by Berghaus (1876), Th. Schmidt (1875), and W. H. Meyer (1887).

Steuben, Frederic William Augustus, Baron, a general of the American revolutionary army, was born at Magdeburg, November 15, 1730, and at fourteen served as a volunteer under his father at the siege of Prague. By 1754 he had risen to the rank of adjutant-general, and in 1762 he was attached to the staff of Frederick the Great. While on a visit to Paris in 1777 he was induced by Count St Germain to go to America. He arrived at Portsmouth, New Hampshire, in February 1778, and offered his services to congress and to General Washington, by whom they were joyfully accepted; and he joined the army, then in the most deplorable condition, at Valley Forge. He was appointed inspector-general, prepared a manual of tactics for the army, remodelled its organisation, and improved its discipline. He sat on the court-martial on Major André. In 1780 he received a command in Virginia, and he took part, as major-general, in the siege of Yorktown. As generous in character as he was capable as an officer, he spent his whole fortune in clothing his men, and gave his last dollar to his soldiers. Congress made tardy reparation, and in 1790 voted him an annuity of 2400 dollars, and a township of land near Utica, New York. There he died in his log-cottage, November 28, 1794. See Sparks's *American Biography,* and a Life by Friedrich Kapp (New York, 1860).

Steubenville, capital of Jefferson county, Ohio, on the Ohio River, 68 miles below Pittsburgh (by railway 43), with blast-furnaces, rolling-mills, machine and railway shops, and manufactories of white-lead, paper, glass, woollens, flour, beer, &c. There are bituminous coal-mines near by, and natural gas is plentiful. Fort Steuben was built here in 1787. Pop. (1890) 13,394.

Stevenage, a town of Hertfordshire, 4 miles SE. of Hitchin by rail, with an old parish church and a grammar-school (1558). Straw-plait is manufactured. Pop. (1851) 2118; (1891) 3309.

Stevens, Alfred, decorative artist and sculptor, was born at Blandford in Dorset, the son of a country painter, in January (baptised on 28th) 1818. When he was helping his father his talent attracted the attention of certain gentlemen, who in 1833 sent him to Italy. There he remained nearly nine years studying painting, though part of the time he assisted Thorwaldsen, the sculptor, in his studio. Three years after his return home Stevens was appointed (1845) teacher of architectural drawing in the School of Design, Somerset House, London; but he held the position only three years. During the next ten years or so from that date he was busily engaged in designing and decorating, in which he displayed the highest genius and taste. He designed in all sorts of materials and for many different purposes—in silver, bronze, iron, marble, and for furniture, churches, porcelain, mantelpieces. From 1856 he laboured at the great achievement of his life, and one of the finest pieces of modelling in England in the 19th century, the monument of Wellington for St Paul's Cathedral; but owing to the greatness of his conception and plan, the inadequacy of means, and other difficulties, it was not completed at his death, which took place at Haverstock Hill, London, on 1st May 1875. It was not till 1892 that steps were taken to remove this magnificent monument from the side chapel, where it was half-hidden, to the place for which it was originally intended. See SCULPTURE, p. 267; and H. Stannus, *Alfred Stevens and his Work* (1891).

Stevens, Thaddeus, an American statesman, was born in Vermont in 1792, graduated at Dartmouth in 1814, was admitted to the Maryland bar, and in 1816 settled as a lawyer in Pennsylvania, where he sat in the legislature for some years. He was a Whig member of congress from 1849 to 1853, and a leader of the Republicans in the House from 1859 till his death, 11th August 1868. He was foremost in all measures for emancipating the negroes, and was chairman of the committee on reconstruction whose bill divided the southern states for a time into five military districts. In February 1868 he proposed the impeachment of President Johnson, was one of the committee which drew up the articles, and chairman of the board of managers appointed to conduct the trial.

Stevenson, Robert, a Scottish engineer, was born at Glasgow, 8th June 1772. His father died during his infancy; and his mother having (1786) married Thomas Smith, the first engineer of the Lighthouse Board, young Stevenson was led to devote himself to the study of engineering, in which his progress was so rapid that in 1791 he was entrusted by Smith with the erection of a lighthouse on Little Cumbrae. In 1796 he succeeded his step-father as engineer and inspector of lighthouses; and during his forty-seven years' tenure of that office he planned and constructed no fewer than twenty-three lighthouses round the Scottish coasts, employing the catoptric system of illumination, and his valuable invention of 'intermittent' and 'flashing' lights. The most remarkable of these erections was that on the Bell Rock (q.v.). In 1814 Stevenson was accompanied in his tour of inspection by Sir Walter Scott. Stevenson was also in great request as a consulting engineer in the matter of roads, bridges, harbours, canals, and railways, introduced many improvements in their construction, and occasionally co-operated with Rennie, Telford, and others. He died in Edinburgh, July 12, 1850. Stevenson left four volumes of professional printed reports, a large work on the Bell Rock Lighthouse, some articles in the *Encyclopædia Britannica* and in the *Edinburgh Encyclopædia.* See the Life (Edin. 1878) by his son, David Stevenson, C.E. (1815-86).

Stevenson, Robert Louis Balfour, brilliant as an essayist, a writer of boys' stories, and a poet of childhood, was born at Edinburgh, November 13, 1850. Both his father and grandfather (Robert Stevenson, q.v.) were famous lighthouse engineers, and he was at first intended for the family profession. But he soon gave up the idea and turned to law, and, after the qualifying course of study at Edinburgh University, was duly called to the Scottish bar. Soon, however, he found his true calling in the craft of letters, and quickly forced his way into the front rank of contemporary writers by the sheer excellence of his style. Some experiences which supplied impulse and material were leisurely journeys through north-eastern France by canoe and on foot, a voyage across the Atlantic in the steerage of an emigrant ship, and the after-journey across the continent in an emigrant train, and, lastly, a lengthened residence in Samoa, whither he went for health's sake in 1889. From his childhood he had written without ceasing, and drunk deep at the richest wells of English undefiled, and from the first his articles in the *Cornhill* and elsewhere showed a distinct individuality and a style perfect if not plus-quam-perfect. His earliest books were *An Inland Voyage* (1878); *Edinburgh: Picturesque Notes* (1878); *Travels with a Donkey in the Cevennes* (1879); *Virginibus Puerisque, and other Papers* (1881); and *Familiar Studies of Men and Books* (1882). The last two contain his best essays, the latter volume those on Charles of Orleans, Pepys, Burns, Villon, &c. In his *New Arabian*

Nights (2 vols. 1882)—a collection of grotesque romances—he opened a new shaft into his wealth of imaginativeness. More important was its next successor, *Treasure Island* (1883), a complete success in a literary kind the secret of which seemed to have been lost. Hardly less excellent was *Kidnapped* (1886); but *The Master of Ballantrae* (1889), *The Black Arrow* (1888), and *The Wrecker* (Scribner, 1891–92) fall into lower rank. In 1885 appeared Mr Stevenson's delightful collection, *A Child's Garden of Verse,* which stands almost by itself as an imaginative realisation of the make-believe and dramatising imagination habitual to childhood. Later volumes of verse were the less notable *Underwoods* (1887) and *Ballads* (1891), which, always clever, usually fall short of the one thing needful in poetry. His *Prince Otto* (1885) failed to please many even of Mr Stevenson's admirers, but the *Strange Case of Dr Jekyll and Mr Hyde* (1886) compelled the most exacting critics to commend its exquisite art and the cleverness with which he puts to artistic use the notion of the double personality in every man. In 1887 he published *The Merry Men and other Tales and Fables,* a collection which contains some of his most delicate work, and *Memories and Portraits*, the interest of which was largely autobiographical. Further writings were the delightful memoir contributed to the collection of Professor Fleeming Jenkin's *Papers* (1887), *Across the Plains,* &c. (1892), and the work on Samoa which alone was needed to make the range of his versatility complete.

See W. Archer in *Time* for November 1885, Henry James in *Partial Portraits* (1888), and Andrew Lang in *Essays in Little* (1890).

Stevenson's Road. See LIVINGSTONIA, TANGANYIKA.

Stevens Point, capital of Portage county, Wisconsin, on the Wisconsin River, 161 miles by rail NW. of Milwaukee, with a number of mills and a trade in lumber. Pop. (1890) 7896.

Stevenston, a town of Ayrshire, ¾ mile inland, and 28 miles SW. of Glasgow. Cotton- and silk-weaving used to be the staple industry of the place, but its prosperity now depends almost exclusively on the neighbouring collieries, ironworks, chemical works, and Nobel's explosives factory. Pop. (1871) 3475; (1891) 4261.

Stevinus, SIMON, mathematician and physicist, was born at Bruges in 1548, held various offices under Prince Maurice of Orange, and died in 1620. He made many advances in mathematics; wrote on fortification, book-keeping, and decimal fractions; and invented a system of water-sluices, and a carriage propelled along the road by sails.

Steward, LORD HIGH, one of the great officers of state, and anciently the first officer of the crown in England (Lat. *dapifer*, *senescallus*). The dignity was in early times hereditary. From Hugh Grentmesnell, Lord Steward in the time of Henry II., it passed by the marriage of his daughter and co-heir to the family of De Bellamont, Earls of Leicester, and thence also by marriage to the Montforts, Earls of Leicester. On the death and attainder of Simon de Montfort, in 1265, the office, reverting to the crown, was granted with the earldom of Leicester to Edmund, younger son of Henry III., and continued annexed to the earldoms of Lancaster and Leicester till absorbed into the royal dignity by Henry IV. Since that time there has been no permanent Lord Steward, but the office is temporarily revived when occasion requires, a Lord Steward being appointed under the Great Seal *pro hac vice* at a coronation or the trial of a peer. When the proceedings are at an end the Lord Steward terminates his commission by breaking his wand of office.

The Steward or High Steward of Scotland was not only chief of the household, but collected and managed the crown revenues, and took the first place in the army next to the king in battle. The office was conferred by David I. on Walter Fitzalan, the founder of the royal house of Stewart (q.v.). The accession of Robert, the seventh High Steward, to the throne as Robert II. merged the seneschalship in the crown; but the estates of the stewards afterwards became the appanage of the king's eldest son, and by act of the Scottish parliament of 1469 the titles of Prince and High Steward of Scotland, Duke of Rothesay, Earl of Carrick, Baron of Renfrew, and Lord of the Isles were vested in the eldest son and heir-apparent of the crown of Scotland for ever. 'Great Steward of Scotland' has thus become one of the titles of the Prince of Wales.

The *Lord Steward of the Household*, in England, was originally designated the Lord Great Master of the Household. He is the head of the ancient court called the *Board of Green Cloth* (q.v.), and as such has the control and selection of all the officers and servants of the household, except those belonging to the Chapel, the Chamber, and the Stable, and also appoints the royal tradesmen. He is always sworn a member of the Privy-council, and has precedence of all peers of his own degree. He has no formal grant of office, but receives his charge from the sovereign in person. He holds his appointment during pleasure, and his tenure depends upon the political party to which he belongs; the salary of the office is £2000.

Stewart, HOUSE OF. The Norman Alan Fitzflaald (died *c.* 1114) got from Henry I. the lands and castle of Oswestry in Shropshire. His elder son, William Fitzalan (*c.* 1105–60), remaining in England, became the ancestor of the Earls of Arundel, from whom, through an heiress (1556), that earldom has passed to the Dukes of Norfolk. The second son, Walter (died 1177), coming to Scotland in the service of David I., had large possessions conferred on him in Renfrewshire, Teviotdale, Lauderdale, &c., along with the dignity of Steward of Scotland, which became hereditary in his family, and gave his descendants the surname of Stewart, by some branches modified to Steuart or the French form Stuart. The Fess Checquy (q. v.), adopted as the arms of the Stewarts, is emblematical of the chequer of the Steward's board. The connection between the Stewarts and the Fitzalans was shown by Chalmers to have been well known and acknowledged so late as 1336, when Richard Fitzalan, Earl of Arundel, for 1000 merks surrendered to Edward III. his 'hereditary right' to the Stewardship of Scotland, which was supposed to have reverted to him through the forfeiture of the Scottish line.

For seven generations the Stewardship descended without a break from father to son. Walter, the grandson of the first Steward, held in addition the office of Justiciary of Scotland, and was one of the ambassadors sent in 1239 to fetch Marie de Couci, second wife of Alexander II. His third son, Walter, called Balloch, by his marriage with the daughter of Maurice, Earl of Menteith, got that earldom, which, by his great-granddaughter, Margaret, was conveyed to Robert Stewart, Duke of Albany, son of Robert II. Alexander, fourth Steward (1214–83), was regent of Scotland in Alexander III.'s minority; he commanded at the battle of Largs (q.v.) in 1263, and, invading the Isle of Man, annexed it to the Scottish crown. From his second son's marriage with the heiress of Bonkyl sprang the Stewarts of Darnley, Lenox, and Aubigné. James, the fifth Steward (1243–1309), was one of the six regents of Scotland after the death of Alexander III. Walter, the sixth Steward

(1293-1326), occupies a conspicuous place among Bruce's companions-in-arms. He did good service at Bannockburn, and four years later successfully defended Berwick against Edward II. in person. His marriage in 1315 with Marjory, Bruce's daughter, eventually brought the crown of Scotland to his family—'It cam with ane lass,' in James V.'s well-known words. His son by Marjory, Robert, seventh Steward (1316-90), on the death of David II. in 1371 ascended the throne as Robert II. He was twice married; first, in 1349, to Elizabeth, daughter of Sir Adam Mure of Rowallan, and secondly, in 1355, to Euphemia, Countess of Moray, daughter of Hugh, Earl of Ross. Elizabeth Mure was related to him within the prohibited degrees, so in 1347 he had obtained a papal dispensation (only discovered in the Vatican in 1789) for the marriage, legitimising those children who had already been born. Hence, in later times, the descendants of this first marriage came to be branded with the suspicion of illegitimacy, while those of the second union would boast their preferable claim to the throne. His third son, Robert (c. 1349-1420), was in 1398 created Duke of Albany; the fourth, Alexander, who in 1374 got the earldom of Buchan on the forfeiture of the Comyns, is infamous in history as the 'Wolf of Badenoch.'

Between 1371 and 1714 (343 years) fourteen Stewarts sat upon the Scottish, and six of these also on the English, throne. A race unhappy as few, they were Robert II. (1316-90); Robert III. (c. 1340-1406), who died of grief, his elder son murdered, his second an English captive; James I. (1394-1437), for eighteen years a prisoner, afterwards murdered; James II. (1430-60), killed at the siege of Roxburgh; James III. (1451-88), murdered, with his son in rebellion against him; James IV. (1473-1513), slain at Flodden—his much-loved mistress, Margaret Drummond, was poisoned; James V. (1512-42), who died broken-hearted by the rout of Solway Moss; Mary (1542-87), beheaded at Fotheringhay, thrice a widow, and for twenty years a captive; James VI. and I. (1566-1625); Charles I. (1600-49), beheaded; Charles II. (1630-85), for fourteen years an exile; James VII. and II. (1633-1701), for twelve years of his youth an exile, and again for the last twelve of his old age; and Mary (1662-94) and Anne (1665-1714), his daughters, who supplanted him, and both died childless. Thus five of the fourteen met with a violent death; two died of grief; and eight succeeded as minors. All the above receive separate articles; but here may be noticed the son and the grandsons of James VII. and II.

By his second queen, Mary of Modena, James had one son, JAMES FRANCIS EDWARD, born at St James's Palace on 10th June 1688. Forty-two privy-councillors, ladies of rank, &c. (more than half of them Protestants) were present in the bedchamber; but the warming-pan fiction fastened on him the nickname of Pretender. Six months later he was conveyed by his fugitive mother to St Germains, where his boyhood was passed, and where, on his father's death in 1701, he was proclaimed his successor. In an attempt, in March 1707, to make a descent upon Scotland, the young 'Chevalier de St George,' as he was styled by his adherents, showed some gallantry, but was not suffered to land; and after his return he served with the French in the Low Countries, at Malplaquet charging twelve times, and in the last charge receiving a sword-thrust in the arm. But in Mar's ill-conducted rebellion (see JACOBITES) he showed himself heavy, spiritless, even tearful, when, too late in the day, he landed at Peterhead (22d December 1715), and sneaked away six weeks afterwards from Montrose. France was now closed to him by the treaty of Utrecht, and almost all the rest of his fainéant, dissolute, prayerful life was passed at Rome, where he died on 1st January 1766. In 1719 he had married the beautiful and high-spirited Princess Clementina Sobieski (1702-65). She bore him two sons, but in 1725 was so disgusted by his preference for the titular Countess of Inverness as to retire for a while to a nunnery. He is buried in St Peter's.

His elder son, CHARLES EDWARD LOUIS PHILIP CASIMIR, known variously as the 'Young Pretender,' the 'Young Chevalier,' and 'Bonny Prince Charlie,' was born at Rome on 31st December 1720. His education was irregular, but from childhood he raised the hopes of the Jacobites by the promise of a bright and chivalrous nature. He first saw service at the siege of Gaeta (1734); fought bravely at Dettingen (1743); and next year repaired to France, to head Marshal Saxe's projected invasion of England. But the squadron which was to have convoyed the transports with 15,000 troops to Kent fled before the British fleet; the transports themselves were scattered by a tempest; and for a year and a half Charles was kept hanging on in France, until at last, sailing from Nantes, he landed with seven followers at Eriska in the Hebrides on 2d August 1745, and on the 19th raised his father's standard in Glenfinnan. The clansmen flocked in; on 17th September Edinburgh surrendered, though the castle still held out; and Charles held court at Holyrood, the palace of his ancestors. There followed the victory over Sir John Cope at Prestonpans (q.v.), the march upon London with 6500 men, the fatal turning at Derby (6th December), the victory over Hawley at Falkirk (17th January 1746), the crushing defeat by the Duke of Cumberland at Culloden (16th April), and Charles's five months' hidings and wanderings, with £30,000 set on his head, in the Hebrides and the western mainland, till on 20th September he got shipping from Moidart to Brittany. The peace of Aix-la-Chapelle (1748) caused his forcible expulsion from France, and thereafter he lived successively at Avignon, Liége, Basel, Florence, and Rome. He seems to have paid two or three secret visits to London between 1750 and 1760; in 1766 succeeded to his father's empty titles; in 1772 married the ill-fated Countess of Albany (q.v.); and for forty years a miserable drunkard, died at Rome, 31st January 1788. By his Scottish mistress, Clementina Walkenshaw, he left a natural daughter, Caroline (1753-89), whom he had created Duchess of Albany. He was buried at Frascati, but translated to St Peter's.

See also COPE (SIR JOHN), CULLODEN, and MACDONALD (FLORA); and A. C. Ewald's *Life and Times of Prince Charles Edward* (2 vols. 1875).

His brother, HENRY BENEDICT MARIA CLEMENT, Duke of York, Cardinal, and Bishop of Frascati, was born at Rome, 5th March 1725. After the failure of the '45, when he had hastened to Dunkirk to support Prince Charles Edward, he resolved to take orders, and in 1747 received a cardinal's hat from Benedict XIV. Clement XIII. consecrated him Bishop of Corinth *in partibus*, and subsequently appointed him to the suburban see of Frascati, where he took up his residence. He enjoyed, through the favour of the French court, the revenues of two rich abbeys, as well as a Spanish pension; and the liberal charity with which he dispensed his income endeared him to his flock. On his brother's death in 1788 he caused a medal to be struck, bearing the Latin legend, 'Henry IX., king of England, by the grace of God, but not by the will of men.' The French Revolution stripped him of his fortune, but in 1796 he sold his family jewels to relieve the necessities of Pius VI. In 1798 the French plundered his villa, and he had to flee for his life to Venice. He returned in 1801 on the restoration of the papal authority, George III. having meanwhile in 1800 granted him a pension of £4000. This last, perhaps best, of the Stuarts died at the age of eighty-two on 13th July 1807. The crown-jewels, carried off from England by James II. 119 years before, were bequeathed by him to George IV., then Prince of Wales, who in 1819 caused Canova to erect a monument in St Peter's that bears the names of 'James III., Charles III., and Henry IX.'

Next to the exiled Stuarts in representation of the royal house as heir-of-line came the descendants of Henrietta (q.v.), Charles I.'s youngest daughter, who in 1661 was married to Philip, Duke of Orleans. From this marriage sprang Anne-Mary (1669-1728), who married Victor Amadeus, Duke of Savoy (q.v.) and king of Sardinia; their son, Charles Emmanuel III. (1701-73), king of Sardinia; his son, Victor Amadeus III. (1726-96), king of Sardinia; his son, Victor Emmanuel I. (1759-1824), king of Sardinia; his daughter, Mary (1792-1840), who married Francis, Duke of Modena; their son, Ferdinand (1821-49), who married Elizabeth of Austria; and their daughter, Maria Teresa (born 1849), who in 1868 married Prince Louis of Bavaria, and whom, as 'Mary III. and IV.,' the 'Legitimist Jacobites' of 1891 put forward as the 'representative of the Royal House of these realms.' Rupert, her son, was born at Munich on 18th May 1869, and is ninth in descent from Charles I.

The branch of the family which the Act of Settlement (1701) called to the throne on the death of Queen Anne were the descendants of the Electress Sophia of Hanover, granddaughter of James VI. and I. by her mother, the Princess Elizabeth (q.v.), Electress Palatine and Queen of Bohemia. By that act not only were the above-mentioned descendants of Charles I.'s daughter, Henrietta of Orleans, excluded, but also the Roman Catholic descendants of the Princess Elizabeth's sons. Her Majesty Queen Victoria is twenty-second in descent from Walter Fitzalan, sixteenth from Robert II., and eighth from James VI. and I.

Before proceeding to glance at the cadets of the House of Stewart we may notice here ARABELLA STUART, who, born in 1575, was the daughter of the Earl of Lenox, Darnley's younger brother, so a great-great-granddaughter of Henry VII., a third cousin to Queen Elizabeth, and a first cousin to James VI. and I. She lost her father at two, her mother at six, and was brought up by her maternal grandmother, the imperious Bess of Hardwick. At the age of twenty-seven, shortly before Elizabeth's death, she was suspected of having a lover in the boy William Seymour, who had Tudor blood in his veins; but on James's accession she was restored to favour, only, however, to contract a secret marriage in 1610 with him. Both were imprisoned, and both escaped—Seymour successfully to Ostend, she unsuccessfully in man's attire, for she was retaken in the Straits of Dover. She died, insane, in the Tower of London, 25th September 1615.

See the Life of her by Elizabeth Cooper (2 vols. 1866) and that by Mary E. Bradley (2 vols. 1889).

The cadets of the house may be divided into four classes: (1) descendants of Robert II.; (2) descendants of natural sons of his descendants; (3) descendants of natural sons of Stewart kings; and (4) legitimate branches of the Stewarts before their accession to the throne. To the first belong the Stuarts of Castle-Stewart, descended from Robert, Duke of Albany, Robert II.'s third son, through the Lords Avondale and Ochiltree. They received the titles of Lord Stuart of Castle-Stewart in the peerage of Ireland (1619), Viscount Castle-Stewart (1793), and Earl (1809). To the second class belong the Stuart Earls of Traquair (1633-1861), descended from a natural son of James Stewart, Earl of Buchan. To the third class belong the Regent Moray (q.v.), the Marquis of Bute, and the Shaw-Stewarts; and to the fourth belong the Earls of Galloway (from a brother of the fifth High Steward), the Lords Blantyre, the Stewarts of Fort-Stewart, and the Stewarts of Grandtully (from the fourth High Steward; the last baronet died in 1890).

See, besides works cited at JACOBITES, under the different Stewart sovereigns, and in Marshall's *Genealogist's Guide* (2d ed. 1885), Stewart genealogies, &c. by Symson (1712), Hay of Drumboote (1722), Duncan Stewart (1739), Noble (1795), Andrew Stewart of Castlemilk (1798), A. G. Stuart (for Castle-Stewart branch, 1854), Sir W. Fraser (for Grandtully branch, 1868), W. A. Lindsay (1888); William Townend, *History of the Descendants of the Stuarts* (1858); the Marchesa Campana de Cavelli, *Les Derniers Stuarts à Saint-Germain en Laye* (2 vols. 1871); Percy M. Thornton, *The Stuart Dynasty* (1890); and Gibb and Skelton, *The Royal House of Stuart* (1890), a finely illustrated work, showing many relics that were exhibited in the Stuart exhibition of 1888-89.

Stewart, ALEXANDER TURNEY, millionaire, was born of Scottish stock at Lisburn, near Belfast, in 1803, emigrated to New York in 1823, and two years later opened his first dry-goods store in Broadway, with a rent of $250; his retail store built in 1862 cost nearly $2,750,000. His charities were numerous and bountiful; yet at his death, 10th April 1876, he left some $40,000,000, which there were no blood relatives to share. See RESURRECTIONISTS, and GARDEN CITY.

Stewart, BALFOUR, LL.D., F.R.S., physicist, was born at Edinburgh, November 1, 1828. He studied at both St Andrews and Edinburgh universities, but in 1846 entered on a commercial career. Seven years later he forsook business, returned from Australia to Edinburgh, and became assistant to Professor Forbes. In 1859 he was appointed director of the Kew Observatory, and in 1870 professor of Physics at Owens College, Manchester. He died, December 19, 1887, near Drogheda, Ireland. He made his first reputation by his work on Radiant Heat (1858), by which he established the equality of the emissive and absorptive powers of bodies. He is rightly regarded as one of the founders of the method of spectrum-analysis, of which the complete theory was given by Kirchhoff a little later (see HEAT and SPECTRUM). In connection with his work on radiant heat the experiments (in conjunction with Professor Tait) on the heating of a rotating disc in vacuo (1865-78) should be mentioned, as should also his remarks on the effect of relative motion on radiation. His other labours were chiefly meteorological, his name being specially associated with such subjects as the relation between sun-spots and temperature and magnetic changes, terrestrial magnetism, and the daily ranges of the meteorological elements. Particularly valuable are his numerous papers on terrestrial magnetism. As a writer of text-books on physics he earned a high reputation, the *Treatise on Heat* (1866; 5th ed. 1888), the *Elements of Physics* (1870; 4th ed. 1891), and the *Conservation of Energy* (1873; 7th ed. 1887) being all excellent works, especially the first. Very concise in statement and suggestive in treatment is his contribution on terrestrial magnetism to the *Encyclopædia Britannica* (article 'Meteorology'). With Professor Tait he published in 1875 *The Unseen Universe, or Physical Speculations on a Future State*, a book which had a phenomenal reception and passed rapidly through several editions (17th ed. 1890).

Stewart, Sir Charles. See Castlereagh.

Stewart, Dugald, philosopher, was born in Edinburgh on the 22d November 1753, and was the son of Matthew Stewart (q.v.). He entered the High School in his eighth year, and remained till his thirteenth. His subsequent course at the university extended from 1765 to 1769. In the departments of study where his own career afterwards lay he was fortunate to find professors of ability and distinction, the moral philosophy chair being occupied by Adam Ferguson. While Stewart gave his highest promise in these subjects he also made great attainments in mathematics and natural philosophy, and likewise in classics. In 1771 he went to study at Glasgow, partly with a view to one of the Snell scholarships at Balliol College, Oxford, and partly to attend the lectures of Dr Reid. It was while there that he wrote an essay on Dreaming, which was his first effort in mental philosophy, and contained the germs of many of his subsequent speculations. He lived in the same house with Archibald Alison, the author of the *Essay on Taste*, and the two became intimate friends through life. He was at Glasgow only one session. In 1772, in his nineteenth year, he was called upon by his father, whose health was failing, to teach the mathematical classes in the university of Edinburgh; in 1775 he was elected joint-professor, and acted in that capacity till 1785. In 1778 Adam Ferguson was absent from his post on a political mission to America, and Stewart taught the moral philosophy class in addition to his mathematical classes. The lectures that he gave on this occasion were wholly his own, and were delivered from notes, as was his practice in after years. On the resignation of Ferguson in 1785 he was appointed professor of moral philosophy, and continued in the active duties of the class for twenty-five years. His lectures were greatly admired and numerously attended. He went over a wide compass of subjects: psychology, or the science of mind proper, metaphysics, logic, ethics, natural theology, the principles of taste, politics, and last of all, political economy, which, from the year 1800, he treated in a separate course. In 1792 appeared his first volume of the *Elements of the Philosophy of the Human Mind*, and in 1793 he published his *Outlines of Moral Philosophy*. He read before the Royal Society of Edinburgh in 1793 his *Account of the Life and Writings of Adam Smith*; in 1796 the *Account of the Life and Writings of Principal Robertson*; and in 1802 the *Account of the Life and Writings of Dr Reid*. In 1805 he took a prominent part in the 'Leslie controversy,' and wrote a pamphlet maintaining Sir John Leslie's claims to the chair of mathematics and defending him from theological aspersions. In 1806, on the accession of the Whig party to power, he received a sinecure office worth £300 a year. The death of his second son in 1809 gave a blow to his health, otherwise indifferent, and he was unable to lecture during part of the following session; Dr Thomas Brown, at his request, acting as his substitute. The following year Brown was appointed conjoint professor, and taught the class till his death in 1820. From 1809 Stewart lived at Kinneil House, near Bo'ness, which the Duke of Hamilton had placed at his service. In 1810 he published his *Philosophical Essays*; in 1814 the second volume of the *Elements*; in 1815 the first part, and in 1821 the second part, of the *Dissertation on the History of Ethical Philosophy*; in 1827 the third volume of the *Elements*; and in 1828, a few weeks before his death, the *Philosophy of the Active and Moral Powers*. On the death of Brown Stewart exerted himself to secure the appointment of Sir William Hamilton to the chair, but the influence used with the town-council in behalf of John Wilson ('Christopher North') was overpowering. Stewart resigned his conjunct professorship on the 20th June 1820; he died 11th June 1828.

The philosophy of Stewart was the following up of the reaction commenced by Reid against the sceptical results that Berkeley and Hume drew from the principles of Locke (see Scottish School). Hence arose the principles of common sense of Reid, in which Stewart for the most part acquiesced. Stewart also followed and improved upon Reid in the systematic exposition of all the powers of the mind which rendered mental philosophy for the first time a subject of study, independent of metaphysical, logical, and ethical applications; although he also followed it out in all these directions with his usual perspicacity and felicity of exposition. His contributions to the philosophy of taste, in the *Philosophical Essays*, are among the best parts of his writings. Although Stewart was not one of the most original thinkers in his department, yet, by the force of his teaching and the compass of his writings, he did much to diffuse an interest in the speculations connected with the human mind. Amongst notable men who studied under Stewart were Lords Jeffrey and Cockburn, Sir Walter Scott, Lord Brougham, Francis Horner, Sir James Mackintosh, James Mill, Lord Palmerston, and Earl Russell.

His works (11 vols. 1854-58) were edited by Sir W. Hamilton, whose work was completed and the biography added by Professor Veitch.

Stewart, Matthew, was born in 1717 at Rothesay in Bute. He studied first at the university of Glasgow, where he was a favourite pupil of Robert Simson, and in 1742-43, when he was a student of divinity in the university of Edinburgh, attended Maclaurin's lectures on fluxions. For a short period he was minister of Roseneath, and in 1747 was elected Maclaurin's successor. He had in the previous year published his *General Theorems of considerable use in the higher parts of Mathematics*. In 1761 he published *Tracts Physical and Mathematical*, and in 1763 his *Propositiones Geometricæ more veterum demonstratæ*. In 1772 he ceased to lecture in the university, and he died on 23d January 1785. The lifelong friendship which existed between him and Simson was unusually cordial, and it is highly probable that the bent of Stewart's mind towards the ancient geometry and his comparative indifference to the modern analysis were due to the example of his master. A biographical account of Stewart by Professor John Playfair will be found in the first vol. of the *Transactions of the Roy. Soc. of Edinburgh* (1788).

Stewarton, a town of Ayrshire, on Annick Water, 5½ miles N. by W. of Kilmarnock. Its specialty is the Scotch bonnet manufactures; but it also carries on carpet-weaving, spindle-making, &c. Pop. (1851) 3164; (1891) 2687.

Stewartry, the name which was given in Scotland to a district governed by a steward, an officer appointed by the king with jurisdiction over crown-lands, and powers similar to those of a lord of regality. While the civil jurisdiction of a steward was equivalent to that of a sheriff, his criminal jurisdiction was much more extensive. The only remaining trace of this jurisdiction exists in the term Stewartry, which in place of county is applied to the district of Kirkcudbright (q.v.; and see Galloway).

Stewing, in Cookery, a very economical way of preparing meat and fruits for food. It differs from boiling in this respect, that only a small quantity of water is used, and the heat applied is so gentle as only to *simmer* it. The more slowly the ebullition is carried on the better. As the small quantity of water is retained as gravy, nothing is lost. Meat prepared in this way is tender and savoury, but, owing partly to the richness of the gravy, is not very digestible. See COOKERY, DIGESTION.

Steyer, a town of Upper Austria, at the confluence of the Steyer and Enns, 36 miles by rail S. by E. of Linz, is the chief seat of the iron and steel manufactures of Austria, turning out firearms, cutlery, files, nails, chains, &c., and also manufacturing paper, leather, beer. Pop. 17,199.

Steyning, a town of Sussex, 1 mile W. of the river Adur and 4½ miles N. of Shoreham. Till 1832 it returned two members. Pop. 1670.

Sticking-plaster. See PLASTERS.

Stickleback (*Gasterosteus*), a genus of Acanthopterous fishes having the dorsal fin replaced by strong spines which vary in number in the different species. The sticklebacks are small, and the male is brightly coloured, the brightness increasing at sexual maturity. They are widely distributed throughout northern and temperate regions. One of the European species, the Fifteen-spined Stickleback (*G. spinachia*), is marine; the other two—the Ten-spined Stickleback (*G. pungitius*) and the Three-spined Stickleback (*G. aculeatus*)—occur in fresh or brackish water, the latter being so abundant in some parts of England that it is used for manure.

Sticklebacks and Nests.

Much interest attaches to the sticklebacks on account of the high degree of parental care exhibited by the male. At the spawning season he constructs a nest of grass and stems of plants firmly cemented together by mucous threads secreted from the kidneys. The nest is barrel-shaped, and has two apertures, thus admitting not only of easy ingress and egress, but also of the constant current of water necessary to the development of the ova. The work of building ended, the eager male, now resplendent in his wedding-robes, sets forth in search of a mate, whom he coaxes to his nest. After she has quitted it, he enters, fertilises the eggs, and immediately resumes his quest, bringing home another and another mate until the nest is filled with eggs. These eggs he guards with jealous vigilance, freeing them from parasites, and attacking every enemy that comes within reach, even though it be a fish many times larger than himself. With the hatching of the ova his labours become for a time more arduous than ever, for the tiny, active sticklebacks must all be kept safe within the shelter of the nest until they are big enough and strong enough to fend for themselves.

Stieler, ADOLF, editor of the well-known *Atlas* (75 plates; Gotha, 1817-23; new ed. 90 plates, 1888 *et seq.*), was born at Gotha on 26th February 1775, and died at the same place on 13th March 1836, having spent his life in the public service of the grand-duchy. A *School Atlas* and a *Map of Germany* (in 25 sheets) by him were also very popular.

Stier, RUDOLF EWALD, German theologian, was born at Fraustadt, March 17, 1800, studied at Jena, Halle, and Berlin, and had already laboured as pastor at Frankleben near Merseburg and Wichlinghausen in the Wupperthal when he was appointed in 1850 superintendent at Schkeuditz, and in 1859 at Eisleben, where he died, December 16, 1862. Stier was a man of fervent and somewhat mystical piety, and as an exegete he shows absolute faith in the inspiration and infallibility of his text; but he has no other dogmatisms, and his books are full of observations always ingenious and edifying, if sometimes prolix and far-fetched.

Among his works the most popular have been *The Words of the Lord Jesus* (Eng. trans. 8 vols. 1855-58), *Words of a Risen Saviour* (trans. 1859), *Words of the Angels* (1862), and *Words of the Apostles* (trans. 1869). See the Life by his sons (Wittenberg, 1868).

Stiff Neck. See NECK.

Stigand, Archbishop of Canterbury, enjoyed great favour with Edward the Confessor, who made him his chaplain, then (1044) Bishop of Elmham or of the East Angles. Eight years later the bishop mediated successfully in the interests of peace between the king and Earl Godwin, and was rewarded with the archbishopric of Canterbury, which had been abandoned by Archbishop Robert. But his appointment was generally looked upon as uncanonical, and was still so regarded even after Stigand received the pallium from Pope Benedict X., Benedict's own election being held to be illegal. On the death of Harold, Stigand gave his vote for Edgar Atheling to be king, and for this reason, and because he was a firm friend of the House of Godwin, William the Conqueror distrusted him, and induced the pope to send a commission of cardinals, who deprived him of his dignities and sentenced him to perpetual imprisonment. But Stigand died shortly afterwards at Winchester; it is said he was starved to death, though whether voluntarily or under compulsion is uncertain.

Stigma. See FLOWER.

Stigmaria, the root of Sigillaria (q.v.) and other trees.

Stigmatisation (Lat. *stigmatizatio*, 'a puncturing,' from Gr. *stigma*, 'a puncture'), the name applied by Roman Catholic writers to the supposed miraculous impression on certain individuals of the 'stigmata,' or marks of the wounds which our Lord suffered during the course of His Passion. St Paul says of himself, 'I bear in my body the marks of the Lord Jesus' (Gal. vi. 15), but his bold metaphor is most likely taken from the notion of soldiers branding on their bodies their general's name. In the early days many Christians branded the name of Christ on their foreheads, and various voluntary mutilations for Christ's sake were practised by enthusiasts. The stigmata comprise not only the wounds of the hands and feet, and that of the side, received in the crucifixion, but also those impressed by the crown of thorns and by the scourging. The impression of the stigmata is by those who believe in its reality regarded as a mark of the signal favour of our Lord, manifested to believers specially devoted to the contemplation of His Passion. The most remarkable example of stigmatisation is that said to have occurred in 1224 to Francis of Assisi, on the mountain of Alverno. Being absorbed in rapturous contemplation of the Passion of Christ, he saw a seraph with six shining wings, blazing with fire, and having between his wings the figure of a man crucified, descend from heaven and approach him, so as to be almost in contact. After a time the vision disappeared, leaving the soul of Francis filled with reverence and awe. And now he became aware that in hands, feet, and side he had received externally the marks of crucifixion. These mysterious marks continued during the two years until his death, and are claimed to have been seen by many eye-witnesses, including Pope Alexander IV.

The Dominicans openly disputed the fact, but at length made the same claim for Catharine of Sienna, whose stigmata were explained as at her own request made invisible to others. The Franciscans appealed to Sixtus IV., and that pope, himself a Franciscan, forbade representations of St Catharine to be made with the stigmata. Still the fact is recorded in the breviary office, and Benedict XIII. granted the Dominicans a special feast in commemoration of it. Many others, especially women, are claimed to have received all or some of the stigmata. The last to be canonised (1831) for this reason was Veronica Giuliani, who is said to have received in 1694 first the marks of the crown of thorns, and afterwards those of the crucifixion. More recent cases are those of Anna Katherina Emmerich (1774–1824), who became a nun at Agnetenberg; 'L'Ecstatica' Maria von Mörl of Caldaro (1839); Louise Lateau (1850–83, in 1868), whose stigmata were stated to bleed every Friday; and Mrs Girling (1827–86, about Christmas 1864), of the New Forest Shaker community. Dr Imbert Gourbeyre, in his work *Les Stigmatisées* (1873), enumerates 145 persons, of whom but 20 were men, as having received the stigmata, and of these 80 lived before the 17th century. Apart altogether from the question of the value of the evidence offered, we may reasonably conclude that some kind of stigmatisation is a pathological condition of occasional occurrence, but from this to the assertion that it is a special sign of divine favour is a wide and an unwarrantable leap.

Stilbite. See ZEOLITE.

Stilicho, a famous Roman general, the mainstay of the western empire after the death of Theodosius the Great, is said to have been a Vandal, and was born about 359. Through his courage and ability he rose rapidly in rank, was sent as ambassador to Persia in 384, and soon after his return rewarded with the hand of Serena, niece of Theodosius. His rise caused a jealousy that soon grew to rankling hatred in the heart of Rufinus, the ambitious minister of Theodosius. In 394 Stilicho departed for Rome in charge of the youthful Honorius, who had been committed to his care, placed him on the throne of the western empire, and administered in his name the affairs of state. On the death of Theodosius (end of 394) Rufinus, the guardian of Arcadius, instigated Alaric to invade Greece while Stilicho was engaged in chastising the invaders of the Roman territories on the Rhine and in Gaul. Returning, he at once set out for Constantinople and destroyed Rufinus, then marched against Alaric, blocked him up in the Peloponnesus, but through over-confidence permitted him to escape across the isthmus with his captives and booty. In 398 his daughter Maria became the wife of Honorius. His old opponent, Alaric, after several inroads upon the eastern provinces of the western empire, now invaded Northern Italy, but was signally defeated at Pollentia (403) and Verona by Stilicho, who had hurriedly called in the Roman legions from Rhætia, Gaul, Germany, and even Britain. Stilicho's ambition now led him to attempt the introduction of his own family to the imperial succession—a statement disbelieved by Gibbon, who considers it merely as an invention of the crafty Olympius—by the marriage of his son with the heir-presumptive Placidia, the daughter of Theodosius, and to attain this end he made overtures of alliance to Alaric, which were gladly accepted. But the dreadful inroad of Radagaisus (406) at the head of more than 200,000 (some say 400,000) barbarians, who ravaged the whole country as far as Florence, compelled the great general of the West to shelve for a time his ambitious schemes. With a small but chosen army of veterans, aided by a body of Huns under Uldin (father of Attila), and of Visigoths under Sarus, he so harassed the invaders that they were forced to give him battle. They were soon completely routed; Radagaisus was put to death, and his followers sold as slaves. Stilicho now returned to his own ambitious schemes, established enmity between Rome and Byzantium by seizing on eastern Illyricum and inducing Alaric to transfer his allegiance to Honorius. But Honorius, who had been prejudiced against Stilicho by one of his officers, Olympius, refused to take eastern Illyricum from the Byzantine empire; and subsequently by an artful harangue he so influenced the soldiers of the army of Gaul that they rose *en masse* against the partisans of Stilicho. Stilicho himself was at Bologna; and on the news of the revolt, his most zealous friends urged immediate action against Olympius and the Pavian rebels; but for the first time in his life vacillation seized the soldier. He was soon forced to flee to Ravenna, where he was murdered, 23d August 408. Thus perished the last of the series of distinguished aliens, who, as emperors, warriors, or politicians, had propped up the Roman empire for 150 years, with a stern and resolute zeal equal to that of the early Romans themselves. Three months after his death Alaric and his Visigoths were at the gates of Rome.

Still is an apparatus for Distillation (q.v.). It consists essentially of a vessel in which the liquid to be distilled is placed, the vapour being conducted by means of a *head* or *neck* to the condenser or worm, where it is cooled by water or other means, and again forms liquid. The still itself varies greatly according to the purpose for which it is used. It is made of copper, iron, earthenware, or glass, and is heated by naked flame or steam-heat. The steam may either be applied on the outside by means of a *jacket* or inside by the use of a *coil*. A *vacuum still* is one in which a partial vacuum is constantly maintained by means of an air-pump, distillation under such circumstances being more rapid and at a lower temperature. See also RETORT.

Stillborn. See OBSTETRICS, ABORTION, and FŒTUS.

Stillicidium. See EAVESDRIP, SERVITUDE.

Stillingfleet, EDWARD, a learned English divine, was born at Cranborne in Dorsetshire on 17th April 1635. There and at Ringwood he received his early education, at thirteen entered St John's College, Cambridge, where he took his degree in 1652, and the year after obtained a fellowship. For some years after leaving college he was occupied as a private family tutor; and in 1657 he was presented to the rectory of Sutton in Bedfordshire. In 1659 appeared his *Irenicum, or the Divine Right of Particular Forms of Church Government examined*, a noble catholic-spirited attempt to find a mean as a basis of union for the divided church. His views savoured somewhat more of latitudinarianism than could be pleasant to the High Church party, and indeed Stillingfleet himself afterwards thought fit to modify them. His *Origines Sacræ, or the Truth and Divine Authority of the Scriptures* (1662), a creditable contribution to the Apologetics of the day, was followed by his *Rational Account of the Grounds of the Protestant Religion* (1664), a defence of the Church of England from the charge of schism in its separation from that of Rome. These works were received with great favour, and quickly led to rich preferment. In 1665 the Earl of Southampton presented him to the rectory of St Andrews, Holborn; he was also appointed preacher at the Rolls Chapel, and shortly after lecturer at the Temple, and Chaplain in Ordinary to Charles II. In 1670 he became Canon Residentiary, in 1678 Dean, of St Paul's. In the Court of Ecclesiastical Commission instituted by James II. Stillingfleet declined to act; and after the Revolution of 1688 he was raised to the bishopric of Worcester. He died at Westminster on 27th March 1699, and was buried in Worcester Cathedral. So handsome in person as to have been popularly called 'the beauty of holiness,' he had, Burnet tells us, a reserved and haughty temper. But he was courteous and temperate in debate, and he had the rare merit for a theologian of being capable of appreciating the courtesy of an opponent. Thus, in the controversy that grew out of his *Mischiefs of Separation* (1680), he candidly confessed himself overcome by the answer of John Howe, who, he said, wrote 'more like a gentleman than a divine, without any mixture of rancour.' Other works were his *Origines Britannicæ, or Antiquities of the British Churches* (1685), and a defence of the doctrine of the Trinity (1697). His collected works, with Life by Dr Timothy Godwin, were published in 1710 (6 vols. folio); a supplementary volume of Miscellanies, edited by his son, in 1735. See Tulloch's *Rational Theology in the Seventeenth Century* (vol. ii. 1872).

Stillwater, capital of Washington county, Minnesota, on the navigable St Croix River (which here expands into a narrow lake), 18 miles by rail NE. of St Paul. It has a large lumber trade, and contains sawmills, a foundry, and flour-mills. Pop. (1870) 4124; (1890) 11,260.

Stilt (*Himantopus*), a widely distributed genus of wading-birds belonging to the Snipe family (Scolopacidæ). They have long slender bills and very long wings and legs, the length of the legs being almost equal to that of the body. The Black-winged Stilt (*H. candidus*) has been occasionally met with in Britain, but is only a rare summer visitor, though it breeds in Holland and southern Europe. The prevailing colours of plumage among the stilts are black and white, but a pure black species inhabits New Zealand.

Stilton, a village of 650 inhabitants in the north of Huntingdonshire, 6 miles SW. of Peterborough. It gives name to the well-known Cheese (q.v., p. 142), most of which now is of course manufactured elsewhere.

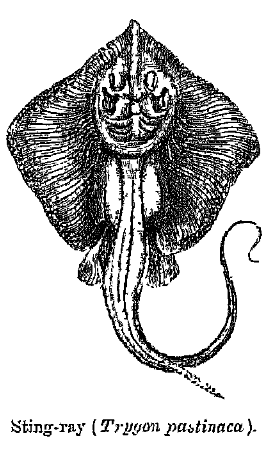
Stilts, poles with steps or supports at a sufficient distance from the lower end to allow a man standing on the steps to walk clear of the ground and with longer strides. Useful in all marshy lands, they were in old days specially serviceable in the French Landes (q.v.), where the shepherds practically spent the whole day on stilts. Elsewhere they serve for crossing streams (as the upper Tweed and Clyde), for a (somewhat dangerous) pastime for boys, and for displays of acrobatic skill. At Namur one of the diversions of the carnival was a tournament between bodies of men mounted on stilts.

Stimulants are agents which increase the activity of the vital functions generally, or of one system or organ. Their action is usually understood as being transient and rapid, but need not necessarily be so. They are most commonly employed to act on the central nervous and circulatory systems, but hepatic, renal, and gastric stimulants are also common terms in medicine. Popularly only those which act on the nervous and circulatory systems are well known, and include alcohol in the form of wines and spirits, sal-volatile, smelling-salts and other preparations of ammonia, besides ether, camphor, various preparations of lavender, peppermint and other essential oils, ginger, &c. Cold and electricity also act as stimulants. They are useful in fainting, nervousness, shock, hysteria, and similar conditions. See the articles on ALCOHOL, ELECTRICITY (MEDICAL), &c.

Sting-fish. See WEEVER.

Stinging-animals. In many different ways animals have the power of stinging. To begin with the minutest, it is likely that the trichocysts of the slipper-animalcule (Paramœcium) have some such power. Almost all the Cœlenterates, such as jellyfish and Portuguese-man-of-war, have Stinging-cells (q.v.), and in a few Turbellarians the same recur, while the dorsal papillæ of some Nudibranch Gasteropods seem to sting the mouths of animals which try to eat them. The stings of ants, bees, and wasps and some other Hymenoptera are abdominal structures, perhaps vestiges of appendages, and they are associated with a poison-secreting gland. The poison of spiders is lodged in the chelicerae or first pair of oral appendages. The sting of the scorpion consists of a double poison-gland lodged in the sharply pointed segment or 'telson' which lies behind the anus at the end of the tail. The sting-rays (Trygonidæ) and the sting-fish or weevers (Trachinus) have no special poison-glands, but it is likely that the slime which enters into the ugly wounds caused by their sharp spines is in part the cause of the inflammation which follows. Among the Scorpænidæ the genus Synanceia has a poison-bag in each of the dorsal spines. Finally, the stinging powers of the venomous snakes are due to the modification of one of the salivary glands on each side as a poison-gland and to the adaptation of the teeth as fangs. In the poisonous Mexican lizard Heloderma an approach to a similar specialisation occurs. See also POISON.

Stinging-cells, or CNIDOBLASTS or NEMATOCYSTS, are characteristic of all Cœlenterata except Ctenophores. To them the jelly-fish, Portuguese-man-of-war, sea-anemones, and the like owe their power of stinging. They protect their possessors against some of their enemies and they serve to benumb or kill the small animals on which most of the Cœlenterates feed. Each stinging-cell contains a long coiled lasso or cnidocil bathed in poisonous fluid; at the base of the cavity in which the lasso lies there is a little living matter and a nucleus; projecting from the surface there is often a small trigger-like peak. When the cell is stimulated, in some cases at least by nervous impulse from adjacent nerve-cells, the lasso, which is many times the length of the cell, is rapidly everted. After this has taken place the cell dies. Often the cnidoblasts are grouped in little 'batteries' especially abundant on the tentacles or similar structures. They are usually situated on the external ectoderm, but are sometimes endodermic. Similar cells occur in some Turbellarian Worms. See CŒLENTERATA, HYDRA.



Sting-ray (*Trygon pastinaca*).

Sting-ray (*Trygon*), a genus of cartilaginous fishes, of the order of Rays (q.v.) and family Trygonidæ. The long tail bears dorsally a long bi-serrated spine, which represents the dorsal fin, and is sometimes about eight inches in length. This is used as a defensive weapon, and gives an ugly wound, often followed by great inflammation, perhaps due to the mucous secretion of the fish, for there is no poison in the strict sense. Some members of the family, e.g. Urogymnus, are without this weapon. The sting-rays are for the most part tropical fishes, and some, e.g. *T. sephen* and *T. uarnak*, attain a large size. Only one species occurs in the British seas (*T. pastinaca*), popularly known as the Fire-flaire. The spine of the sting-ray is used by the savages of the South Sea Islands as a point to their spears.

Stinkpot. See ASPHYXIANTS.

Stinkstone, or SWINESTONE, a kind of marble or limestone remarkable for the fetid urinous odour which it emits when rubbed. It contains a little sulphur.

Stink-trap. See SEWAGE.

Stink-wood (*Oreodaphne fœtida*), a tree of the natural order Lauraceæ, a native of the Cape of Good Hope, remarkable for the strong disagreeable smell of its wood, which, however, is hard, very durable, takes an excellent polish, and resembles walnut. It has been used in shipbuilding.

Stint. See SANDPIPER.

Stipa. See FEATHER-GRASS.

Stipend. The stipend is the provision made for the support of the parochial ministers of the Church of Scotland. It consists of payments in money or grain, or both, made out of the tithes or teinds of the parishes (see TEINDS). Accordingly it varies in amount with the extent of the parish and the state of the free teinds, or of any other fund specially set apart for the purpose. By the Act 1617, chap. 3, power was given to commissioners named under the act to modify, at their discretion, a perpetual local stipend to the ministers of all parish churches from the parochial teinds. The maximum stipend to be given by the commissioners was 10 chalders victual, or 1000 merks (£55, 11s. 1⅓d.) per annum, or proportionally money and victual, with a manse and glebe. Commissions with more liberal powers were appointed in 1621, and again in 1627 and 1633 and subsequent years. Shortly after the Union the powers vested in the commissioners under the then extant commissions were transferred to the Lords of Council and Session, sitting as a Court of Commission of Teinds; and the exclusive powers of the Court of Session in assigning, modifying, and 'localling' stipends were left intact by the Judicature Act. When the existing stipend of a minister is deemed insufficient, the Court, provided there remains any surplus or free teind in the parish, may award out of it such augmentation of stipend as is considered suitable. But no augmentation can be applied for within twenty years after the last augmentation. By statute 50 Geo. III. chap. 84, all stipends which come short of £150 per annum are made up to that amount from government funds—a sum of £10,000 annually being set apart from the revenue for that purpose. By 5 Geo. IV. chap. 72, a parish minister who has neither manse nor glebe, and whose income is under £200 per annum, is entitled to an allowance making up his stipend to a sum not exceeding that amount; if there is a manse but no glebe, or a glebe but no manse, the minister's income may be supplemented so as to ensure him £180 per annum. Ministers under these acts are also entitled to an allowance of £8, 6s. 8d. for communion elements. By 7 and 8 Vict. chap. 44, the stipend of *quoad sacra* parishes is fixed where there is a manse at not less than £100 per annum, and where there is no manse at not less than £120 per annum. These stipends are voluntary, being provided through the endowment schemes of the Church, and the Acts 50 Geo. III. chap. 84, and 5 Geo. IV. chap. 72, have no application to the ministers of such *quoad sacra* parishes.

The terms at which stipend is payable are Whitsunday and Michaelmas. The reason why Michaelmas (29th September) is taken in preference to Martinmas is that the stipend is held to come in place of the tithes, which were due at the separation of the crop from the ground. Where the incumbent is admitted before Whitsunday he is entitled to the whole year's stipend, because his entry is considered as prior to the sowing of the corn; and, for the same reason, if his interest has ceased before that term, he has no right to any part of the fruits of that year. If he has been admitted after Whitsunday, and before Michaelmas, he is entitled to the half of that year's stipend; and in the same way the incumbent whose interest ceases between Whitsunday and Michaelmas has a right to the half-year's stipend, and if his interest does not cease till after Michaelmas he gets the stipend of the whole year. The stipend accruing during a vacancy was formerly at the disposal of the patron of the parish for pious uses; but by statute 54 Geo. III. chap. 169, it was given to the Ministers' Widows Fund. On the decease of a minister a sum equal to a half-year's stipend is payable to his family or nearest of kin (see ANNATES).

Stipendiary Magistrates. See BOROUGH.

Stirling, the county town of Stirlingshire, stands on the south bank of the winding Forth, 36 miles NW. of Edinburgh and 29 NNE. of Glasgow. Like Edinburgh, to which in its main features it bears a striking resemblance, it no doubt owes its origin to the strong natural fortress of its Castle Hill, which rises gradually from the east to a height of 420 feet above the sea or 340 above the plain, and fronts the west with a steep precipitous wall of basaltic rock. The Castle, which commands magnificent views of the Grampians, the Ochils, and the 'Links of Forth,' dates from immemorial antiquity, though few, if any, of the existing buildings are earlier than the days of the Stewart sovereigns, who often kept court here. These include the Douglas room (where the Earl of Douglas was stabbed by James II., 1452), James III.'s parliament-hall (now a barrack-room), James V.'s palace, and James VI.'s chapel (now a store-room). Stirling has many other objects of interest, as Argyll's Lodging (1630, since 1799 a military hospital); ruined Mar's Work (*c.* 1570); Greyfriars Church, so called, but properly the church of the Holy Cross, or Holy Rood, the parish church of Stirling (in 1656 divided into two); the colossal statue of Bruce (1877); the new cemetery, with half-a-dozen statues of Reformers and Covenanters and a marble group of the Wigtown martyrs; Cowane's Hospital or the Guildhall (1637); the King's Knot and King's Park; the Mote or Heading Hill; the old four-arch bridge (*c.* 1400—the 'key of the Highlands'); Robert Stevenson's new bridge (1832); and the Smith Institute (1874), with picture-gallery, reading-room, library, and museum, where now is preserved the 'Stirling Jug' (1497), the standard of the old Scots pint. Other modern edifices are the County Buildings (1875), the public hall (1883), and the High School (1855–89). In the neighbourhood are Bannockburn (q.v.); the ruins of Cambuskenneth Abbey, founded by David I. in 1147 for Augustinian monks, and the burial-place of James III.; and the Abbey Craig (362 feet), crowned by the Wallace Monument (1861–69), a tower 220 feet high. Stirling has manufactures of tartans, tweeds, carpets, agricultural implements, &c. A royal burgh as early as 1119, it unites with Dunfermline, Culross, Inverkeithing, and Queensferry to return one member to parliament. Pop. (1851) 12,837; (1881) 16,013; (1891) 16,895. Stirling (formerly *Stryvelyne* or *Estrivelin*, and also *Snowdoun*) has a wealth of historic memories—the death of Alexander I. and William the Lion; Wallace's victory of Stirling Bridge (1297); the great siege of the castle by Edward I. (1304); the birth of James III.; the coronation of Queen Mary; the baptism and coronation of James VI.; the slaughter of the Regent Lennox (1571); the birth of Prince Henry (1594); the capture of the castle by Monk (1651); and its unsuccessful siege by the Jacobites (1746).

See *History of the Chapel Royal of Stirling* (Grampian Club, 1882), and *Charters of Stirling* (Glasgow, 1884).

Stirling, JAMES HUTCHISON, the most eminent of later Scottish philosophers, was born at Glasgow, June 22, 1820, took the course in both arts and medicine at Glasgow University, and practised a short time as a physician in South Wales. He next went to Germany, and gave himself devotedly for some years to the study of philosophy. The publication of his masterly and epoch-making work, *The Secret of Hegel: being the Hegelian System in Origin, Principle, Form, and Matter* (2 vols. 1865), opened up an unknown world to English readers, and gave a powerful impulse to the study of philosophy generally. It would be difficult, perhaps impossible, to find in the entire range of the literature of philosophy a higher masterpiece of exposition than this combination of erudition, analytic genius, and perspicuity. To this work, as full of individuality as learning, there followed in 1881 a complete *Text-book to Kant*, comprising a translation and reproduction of the *Critique of Pure Reason*, with a commentary and biographical sketch. These two works stand together in the most intimate relation, for, according to Stirling, from Kant's antecedent system Hegel's philosophy itself was but 'a development into full and final shape.' At the same time Dr Stirling brought Kantian speculation into line with English thought by demonstrating that the central problem of the critical philosophy was a question that had been already propounded, if not answered, by Hume. Stirling received the degree of LL.D. from Edinburgh in 1867, and was elected a foreign member of the Philosophical Society of Berlin in 1871. He delivered the first course of Gifford Lectures at Edinburgh, and these were published in 1890, the whole forming a vigorous if somewhat discursive work, in which natural theology is considered in its relation to the history of philosophy, and investigated mainly from the point of view of reason and the principles involved in the Theistic inference. Of the famous three proofs—the Teleological, the Cosmological, and the Ontological—he deals mainly with the first. 'Begin with which we may, and let them be separated from each other as they may be in time, the three, after all, do constitute together but the three undulations of a single wave, which wave is but a natural rise and ascent to God, on the part of man's own thought, with man's own experience and consciousness as the object before him.' Other works of Dr Stirling's are *Sir William Hamilton: being the Philosophy of Perception* (1865), an assault on Hamilton's doctrine of perception more serious still than Mill's; an excellent translation of Schwegler's *History of Philosophy* (1867; 11th ed. 1891); *Jerrold, Tennyson, and Macaulay*, &c. (1868); *As Regards Protoplasm* (1869; complete ed. 1872), a convincing answer to Huxley's *Essay on the Physical Basis of Life*; *Lectures on the Philosophy of Law* (1873), together with an incisive attack on Whewell and Robertson Smith for their errors in statements anent Hegel's relations to Newton's philosophy and the study of the calculus; *Burns in Drama, together with Saved Leaves* (1878); besides a few weighty lectures on such subjects as Materialism, Philosophy in the Poets, the Community of Property, Nationalisation of Land, &c. He contributed the article on Kant to the present work.

Stirling, WILLIAM ALEXANDER, EARL OF, minor Scottish poet, a contemporary and dear friend of Drummond of Hawthornden, was born at Menstrie House near Alloa, most probably about 1567—hardly so late as 1580, the usual date formerly given. He studied at Glasgow and Leyden, travelled through France, Spain, and Italy with Archibald, seventh earl of Argyll, and began his career as a poet by publishing at Edinburgh, in 1603, his tragedy of *Darius*, quickly followed by *Aurora*, a collection of sonnets (Lond. 1604), *Crœsus* (together with *Darius*, 1604), the *Alexandrian Tragedy* (1605), and *Julius Cæsar* (1607). These were collected as *The Monarchicke Tragedies* in 1607. He was knighted by 1609; in July 1613 was attached to the household of Prince Charles, as before he had been to Prince Henry's; in 1614 was made Master of Requests for Scotland, publishing the same year the first part of his great poem of *Doomesday* (second part, 1637), which extends to 11,000 verses, and which himself even allows in the dedication to be of 'too melancholic a nature for young minds.' He received in 1621 the grant of 'Nova Scotia'—a vast tract of Canada and the northern part of the modern United States—his charter being renewed in 1625; and in 1631 he received the patent of sole printer for thirty-one years of King James's version of the Psalms, a work to which he had contributed greatly, but which proved an utter failure. In 1626 he was made Secretary of State for Scotland, which office he held till his death, despite his unpopularity. Baillie writes of him as 'extreamly hated of all the country, for his alleged briberie, urgeing of his psalms, and the books for them.' In 1627 he was made Keeper of the Signet, a Commissioner of Exchequer in 1628, and one of the Extraordinary Judges of the Court of Session in 1631. The French pushed their conquests in America, and Alexander's grant of lands thereby became useless. He was promised £10,000 compensation, but the money was never paid. In 1630 he was created Lord Alexander of Tullibody and Viscount Stirling. In 1633, at the crowning of Charles in Holyrood, he was made Earl of Stirling and Viscount Canada, in 1639 also Earl of Dovan, but he sank into insolvency, and died in London, 12th September 1640. His body was embalmed and buried at Stirling a few months later. The title died out with the fifth earl in 1739. His tragedies are not dramatic, but their quatrains are gracefully written, albeit the quantities are monstrous—witness Ixĭon, Nicănor, Orĭon, and Eumēnes. The *Parænesis* to Prince Henry is perhaps his finest work; the songs, sonnets, elegies, and madrigals forming the *Aurora* are sadly marred by conceits, yet show rich fancy and ingenuity, though scarce even a Scotchman can claim for them that they sparkle still the right Promethean fire. These amatory poems the author did not include in his collected *Recreations with the Muses* (folio, 1637). A complete edition of his poems appeared at Glasgow, in 3 vols., in 1870.

See the Rev. Charles Rogers, *Memorials of the Earl of Stirling and the House of Alexander* (2 vols. 1877).

Stirling-Maxwell. See MAXWELL.

Stirlingshire, a midland county of Scotland, forming the border-land between Highlands and

Lowlands, is bounded by Perth, Clackmannan, Linlithgow, Lanark, and Dumbarton shires. With a maximum length and breadth of 46 and 22 miles, it has an area of 467 sq. m., or 298,579 acres, of which 3294 are foreshore and 8946 water. The Forth traces much of the northern and all the north-eastern boundary; on the western lies Loch Lomond; and other lakes and streams belonging partly or wholly to Stirlingshire are Lochs Katrine and Arklet, and the Avon, Carron, Bannock, Endrick, and Blane. Ben Lomond, in the north-west, attains 3192 feet; and lesser elevations are the Gargunnock Hills (1591 feet), Kilsyth Hills (1393), Campsie Fells (1894), and Fintry Hills (1676). A considerable part of Stirlingshire is occupied by the carses of Stirling and Falkirk, which were formerly covered for the most part with unproductive moss. On the removal of the moss-soil, part of which was floated off into the Forth by the agency of running water, a rich clay soil, of various depths, from a plough furrow to 20 or even 30 feet, was reached, and now is cultivated with the most marked success. About 40 per cent. of the whole area of the county is in cultivation; woods cover 14,211 acres. Coal and ironstone are largely mined; and there are the great ironworks of Carron and Falkirk, besides manufactures of woollens, cotton, chemicals, &c. The chief towns are Stirling, Falkirk, Kilsyth, Denny, and Grangemouth. The county returns one member to parliament. Pop. (1801) 50,825; (1841) 82,057; (1881) 112,443; (1891) 125,604. Antoninus' Wall is the principal antiquity; and no fewer than six battles have been fought within Stirlingshire—Stirling Bridge, 1297; Falkirk, 1298; Bannockburn, 1314; Sauchieburn, 1488; Kilsyth, 1645; and Falkirk, 1746.

See the articles on the above battles, towns, &c.; and Nimmo's *History of Stirlingshire* (1777; 3d ed. 1880).

Stitch in the side is the popular and expressive name applied to sharp pains felt in various parts of the side. It seems that these may be due to various causes; thus, they may be associated with pleurisy where there is no effusion, or with a stretching of the not uncommon adhesions between two pleural surfaces, or simply with local spasms of the respiratory muscles, as when a person takes violent exercise after a full meal, or perhaps even with a slight twisting of part of the intestine. When the stitch is but slight it is often removed by stooping, hence the popular remedy is to make a cross upon the foot.

Stitchwort. See STARWORT.

Stiver (Dutch *stuiver*), a coin of Holland, equivalent to a penny sterling, being the $\frac{1}{20}$th of a guilder or gulden. See FLORIN.

Stoat. See ERMINE.

Stobæus, JOANNES, a native of Stobi in Macedonia, who compiled for his son Septimus, about 500 A.D., an anthology in four books from as many as 500 Greek poets and prose-writers. It has preserved for us fragments from many works now lost, and is especially rich in quotations from the Greek dramatists. Originally forming one whole, the work in course of time became divided into two divisions, each of two books: *Eclogæ Physicæ et Ethicæ* (ed. Gaisford, 1850; Meineke, 1860-64), and *Anthologion* or *Florilegium* (Wachsmuth, 1884), containing the precepts on political and ethical subjects (ed. Gaisford, 1822-25; Meineke, 1856-57).

Stock, or STOCK GILLYFLOWER (*Matthiola*), a genus of plants of the natural order Cruciferæ, having cylindrical or compressed pods, and a stigma consisting of two upright appressed plates, the outer side of which often rises into a knob or horn. The species are herbaceous, annual or perennial, or half-shrubby, natives of the countries around the Mediterranean Sea, most of them thickly clothed with white or grayish stellate hairs; the flowers in racemes, and generally beautiful and fragrant. Some of the species have long been much cultivated, and many fine varieties have been produced by cultivation. *M. incana*, a very rare and even doubtful native of England, is probably the parent of the greater number of the cultivated kinds with hoary leaves, known as Brompton Stock, &c.; whilst those with smooth leaves, called Ten-week Stock, German Stock, &c., are referred to *M. annua*, *M. glabra*, and *M. fenestralis*, which, perhaps, are mere varieties of one species. The sandy shores of Wales and of Cornwall produce a species, *M. sinuata*, the large purple flowers of which are fragrant only at night—a characteristic also of several other species. Stocks are always raised by gardeners from seed, which even the double kinds often produce, a multiplication of the petals having taken place without loss of the parts of fructification. Of the seedlings, however, some produce double and others single flowers, so that only some gratify the cultivator. The hoary-leaved stocks are generally treated as biennials, although, in reality, they may almost be reckoned perennial; and it is not desirable that they should flower in the first year, as the plants become stronger when they remain without flowering till the second year, and produce richer racemes of flowers. The smooth-leaved stocks are treated as annuals. The beautiful little annual called Virginian Stock does not belong to this genus, although it is of the same natural order. Its habit is indeed very different. It is *Malcolmia maritima*, and, notwithstanding its popular name, is a native of the shores of the Mediterranean. It has become one of the most favourite British flowers, almost rivalling mignonette, and is all the more esteemed because it grows well in the little garden-plots which are exposed to the smoke of towns.

Stockbridge, a little market-town of Hampshire, on the Anton or Test, 8 miles W. by S. of Andover. Till 1832 it returned two members to parliament; Steele at one time was its representative. It has a well-known racecourse and training stables. Pop. 873.

Stock-exchange. The London Stock-exchange as a corporate body only dates from the commencement of the 19th century. Prior to the establishment of the Stock-exchange in 1801 transactions in the funds were conducted in a very slipshod manner by groups of individuals, who till about 1698 used the old Royal Exchange in London as a meeting-place, and then for a century made one of the network of alleys in Cornhill their headquarters, congregating in Change Alley both in the open air and in the Jonathan and Garraway coffee-houses. Dealings in government funds were also conducted in the Rotunda Room in the Bank of England. The founders of the Stock-exchange acquired premises in Capel Court, facing the eastern side of the Bank of England. The original capital subscribed for providing the accommodation was 400 shares of £50 paid. Nothing further was required for upwards of half a century in the way of capital, though very considerable expenditure, especially since 1870, has raised the total outlay for the old building and extensions to over half a million sterling. In the early days of stock-dealing transactions were almost entirely in the different forms of British government funds, lottery bonds, and floating debt; but Change Alley, just as Capel Court in the 19th century, had wild fits of gambling in company schemes, of which the most memorable, the South Sea Scheme (q.v.), culminated in 1720.

At the time the first stone of the Stock-exchange building was laid in 1801 the total national debt of Great Britain was some £550,000,000, and the Stock-exchange list, published bi-weekly, comprised only six securities, chiefly British government stocks. Foreign governments first came to the English market as borrowers in 1820 to 1825, and the bonds of various European and American states, Russian, Portuguese, Neapolitan, Danish, Greek, Colombian, Mexican, Buenos Ayres, Chilian, Peruvian, &c., came to be dealt in. There were also transactions in a few canal, insurance, and industrial companies. Numerous banking corporations were established immediately after 1833. The introduction of railways in the United Kingdom and on the Continent in the period from 1840 to 1846 added largely to the business of the Stock-exchange. The gold-discoveries of 1848–50 brought about the formation of a crowd of mining schemes. The introduction of joint stock companies after the Act of 1862, the growth of foreign government debts, and the introduction of Indian and colonial borrowings, municipal loans, gas, water, shipping, telegraph, tramway, &c. undertakings, as well as United States, Indian, and South American railroad securities, have so added to the official list of the London Stock-exchange that the nominal amount of stock and securities quoted in the list that appears daily under the authority of the committee was at 31st December 1891 to the amount of £6,347,000,000, or, deducting foreign loans with coupons payable abroad, £4,562,000,000; and this is exclusive of an enormous amount of capital of miscellaneous company issues, which individually have not been of sufficient importance to obtain a quotation in the official list. These latter though not quoted are dealt in.

As regards the United Kingdom, beyond the London Stock-exchange there are various provincial establishments for conducting business in public securities. Manchester, Liverpool, Leeds, Birmingham, Bristol, Glasgow, Edinburgh, Dublin, Belfast, and other important centres of the United Kingdom have their stock-exchanges administered by committees, and having rules and regulations much on the same lines as those of the great London establishment. On the Continent, too, every important city has its stock-exchange or *Bourse*. New York (about 1100 members in 1891), Philadelphia, Baltimore, Chicago, San Francisco, and some other important American cities have their stock-exchanges; and there are also similar establishments termed *Bolsas* in leading cities of South American states. Transactions in public funds and securities of joint-stock companies, &c. are also conducted in leading Indian and colonial cities.

At the time when the London Stock-exchange was opened in 1802 there were 551 members and 99 clerks, and in March 1891 the roll of members included upwards of 3000 names, besides an army of clerks having admission. In 1821 each member was required to provide two sureties for the sum of £250 each, who also had to be members, and were held liable in their suretyship for two years. Various alterations have since been made, and the suretyship for new members is now three members responsible for the sum of £500 each for four years. Those persons who have served as clerks for a period of four years are, however, only called upon to provide two sureties of £300 each for four years. Members have to pay an entrance-fee of 500 guineas and an annual subscription of 30 guineas. The entrance-fee for members who have acted as clerks is 150 guineas.

Although the London Stock-exchange is not, as generally is the case on the Continent, in any way controlled by the government, and has not a monopoly, it practically secures the whole of the *bonâ fide* business of buying or selling British government securities. Its members voluntarily place themselves under most stringent rules and regulations, and the slightest irregularity is visited with prompt pains and penalties. The committee is entrusted with the power of investigating complaints between members, or between the public and members, and any departure from orthodox procedure can be visited with penalty of suspension or expulsion. One of the regulations is that no member is allowed to advertise for business. Thirty members are annually balloted for to serve as a committee, and there is no appeal from judicial decisions that may be made by that body.

Members act as brokers and jobbers. The *broker* transacts business as between members of the Stock-exchange and the public, obtaining his commission from the clients who employ him. He deals in all securities. The *jobber or dealer* confines his attention to some special group of securities, and generally offers to buy at one price or sell at a higher any of the group stocks or shares he specially may interest himself in. The margin between the buying and selling price he may quote to any broker varies according to the nature of the security, the extent of competition, the state of the market, &c. In some active stocks the margin may be as little as ⅛ of 1 per cent.: or if the stock is one that is rarely dealt in the jobber may quote a difference of 5 or even 10, and also say he is a buyer or seller only at a price, and refuse to deal unless what he is prepared to offer is acceptable to the broker.

On some of the continental bourses the conditions of membership are much more stringent than in England. On the Paris Bourse, for instance, there are sixty-five officially recognised *agents de change*, whose appointment rests with the government. As a body these sixty-five are termed the *Parquet*. Each member of the Parquet has to deposit on appointment cash or securities to the value of £10,000, and the Parquet as a body guarantees transactions from the fund, to which is added accumulating interest and a payment to the fund by each member of 15 centimes on each bargain. Intermediaries between the Parquet and the public are numerous. Reputable firms also have a guarantee fund of their own. These brokers, as they would be termed in England, are known as the *Coulisse*.

An enormous amount of business is transacted between international exchanges by means of telegraphic communication. If, for instance, an event occurs that causes sharp changes in prices, it may happen that the price of some special security of an international character is appreciably different on one exchange from what it is on another. Italian government funds may be quoted in Paris at a much higher price than in London, after making allowance for exchange rate, &c. Certain dealers who closely watch the margins in price between markets instantly send telegrams from different markets in which Italian rente is dealt in, say from Paris to buy in London, or from London to sell in Paris. This *arbitrage* business is conducted between the exchanges of all the world. There is much intricacy in calculations as to what is parity, as, for instance, in London or in Paris the quotation of a security includes the interest or dividend accrued since the last payment, while on the German bourses securities are bought at a price for the principal, and the amount of accrued interest or dividend has to be paid beyond the principal sum. There is only one notable exception on the London Stock-exchange to the price being inclusive of principal and accrued interest. This exception is India rupee paper, where the purchaser buys at the quotation for the principal and pays the vendor of the security the amount of accrued interest.

Stock-exchange securities are of two characters, inscribed or registered, and to bearer. In home government funds and several colonial and municipal ‘inscribed’ issues the names of stockholders are registered (*inscribed*) in books kept at the Bank of England, or other banking agents of the government or corporation. When such stock is sold the vendor or his attorney must attend the bank and sign the transfer in the books. Where stock in a railroad or other company that registers the name of the stockholder is sold by the *registered* proprietor a deed of transfer, subject to stamp-duty, has to be executed, and this deed, with the stock or share certificate, is passed to the purchaser, who directly or through his agent lodges them with the company for registration into his own name. Securities *to bearer* are those the title to which passes by mere delivery, and the interest or dividends are paid periodically by means of coupons.

Almost all stock-exchange transactions in Great Britain are purchases or sales for what is termed the *settlement*. There are cash transactions for immediate payment or delivery, but except for consols bargains for cash are exceptional. The settlements are periodical—monthly in the case of home government funds and bi-monthly in other securities. The *Consols settlements* fall due about the first or second day of the month, sometimes a day or two later. *Settlements* in foreign and colonial government bonds, railway, and other industrial and miscellaneous securities are fixed to fall in the middle and at the end of each month. In dealing in registered securities it is necessary for the purchaser or seller to furnish the broker entrusted with the business with full particulars. A purchaser should give his full name, address, and occupation. A seller is required to forward to the broker the certificate of title. Where the transaction is in securities to bearer the vendor simply has to hand the securities to his broker, and the transaction is in all respects similar to the exchange of a bank-note for cash.

On the Paris Bourse settlements are arranged each fortnight in foreign government and miscellaneous securities, and monthly in French rentes, City of Paris bonds, Bank of France shares, Credit Foncier securities, and French railway stocks. The ‘settlement’ (*liquidation*) occupies five or six days, and except for intervening holidays or Sundays the procedure is as below :

	Monthly Liquidation ; options declared last day of month		Fortnightly Liquidation , 16th of month, also carrying over.	
Rente continued	1st	next month	..	
Other securities continued	2d	„	16th	of month.
Accounts made up.	3d	„	17th	„
Clients pay brokers and deliver securities........	4th	„	18th	„
Brokers pay clients.......	5th	„	19th	„
Brokers deliver securities..	6th	„	20th	„

In Berlin the last day of the month is ‘pay’ day, and five days before is option day. In New York transactions are for cash, with daily settlements.

A very large proportion of the business done in the stock-markets is speculation done in *time bargains*. A purchaser who imagines that some special security is likely to rise in price buys for the settlement, in the hope of being able to sell at a profit before the date for payment falls due. If a change in price the way he expects is delayed, he renews the transaction from settlement to settlement. It may be the case that a fall in price is expected, and an operator sells in the hope of being able to buy back at a lower price. The purchaser for a higher quotation is in stock-exchange parlance called a *bull*. The seller who anticipates a fall in prices is termed a *bear*. If there is a preponderance of bull speculation high terms are asked for the loan of money on the security of stock, termed a rate of *contango*, which may be expressed as so much per share or per cent. on the nominal hundred pounds of capital, or it may be a rate per cent. upon the actual amount of money to be borrowed. If many persons have formed an adverse opinion as to the course of the market, and there is what is termed an oversold state of the account, it frequently happens that those *bears* who have sold what they do not possess are called upon by real owners of stock, shares, or bonds to provide a bonus, termed *backwardation*, to pay the holder of the security for the trouble and risk attendant on lending it to the seller. Sometimes a long continued speculation for the fall is attended with very high backwardation charges, and not infrequently violent fluctuations in the price of the security. Combinations to resist the adverse effect of sales by speculators for the fall are sometimes entered into in face of really adverse circumstances. A powerful group with command of money finding that ‘bear’ operations in a security of which the amount is small have been entered into to an excessively imprudent extent, buy all the stock that is offered, and call upon those who have sold what they do not possess to deliver it. This results in what is called a *corner*, and the operators who have sold have to pay whatever price the operators who have bought like to ask. An instance in point may be quoted. A South American government some years ago came upon the market as a borrower of a million pounds. The government was not one in good credit, and heavy speculative sales of the bonds were made on the expectation that there would be a fall in price of the bonds; but parties interested in bringing out the loan bought more of it than there was in existence, being enabled to do so through the sales of persons who sold what they did not own, and called upon those who had sold bonds to deliver them. For some months they continued raising the price against those who had sold, and at each fortnightly settlement exacted rates of backwardation sometimes as high as the equivalent of about 100 per cent. per annum. The loan was issued to the public at the price of 80 per cent., and was raised to very near £100 in cash for the £100 bond. The purchasers forced those who had sold to buy back, and after the successful coup the views taken by the adverse party were found to be perfectly correct, for eventually the price receded to about £4 for the £100 bond. *Corners* have been very frequent on the New York and Chicago Stock-exchanges.

A large amount of speculation in stock-exchange securites is conducted on what is known as *option* business. Options can be of threefold character—the payment of a sum for the right to purchase or to sell at a future date at an agreed price, or the right to sell only, or again the right to buy only. These options are termed respectively (1) the *put and call*, (2) the *put*, (3) the *call*. In America the double option of *put and call* is termed a *straddle*. This option business enables any operator to enter into speculative engagements with a known maximum of loss.

Gibson, *The Stock Exchanges of London and New York* (1889); Burdett's *Official Intelligence*, issued under the sanction of the London Stock-exchange Committee; the *Stock Exchange Year-book*, by T. Skinner; besides works on the fluctuations of stocks by Crump (1875), Giffen (1879), Ellis (1879); on the law and usages of the Stock-exchange, works by Paterson, Royle, Melsheimer, Lawrence, and Stuttfield (1891); and American works by Lewis, Biddle, Dos Passos, and Cook; also the article BROKER.

Stock-fish, a commercial name of salted and dried cod and other fish of the same family, particularly the Ling, Hake, and Torsk.

Stockholm, the capital of the kingdom of Sweden, stands on several islands and the adjacent mainland, between a bay of the Baltic and Lake Malar, in a situation that is accounted one of the most picturesque in Europe. The nucleus of Stockholm is an island in mid channel called 'the Town;' on it stand the imposing royal palace (1697–1754); the principal church (St Nicholas), in which the kings are crowned; the House of the Nobles (1648–70), in which that class hold their periodical meetings; the town-house; the ministries of the kingdom; and the principal wharf, a magnificent granite quay, fronting east. Immediately west of the central island lies the Knights' Island (*Riddarholm*); it is almost entirely occupied with public buildings, as the Houses of Parliament; the old Franciscan church, in which all the later sovereigns of Sweden have been buried; the royal archives; and the chief law-courts of the kingdom. To the north of these two islands lie the handsomely built districts of Norrmalm, separated from them by a narrow channel, in which is an islet covered with the royal stables. The principal buildings and institutions in Norrmalm are the National Museum (1850–65), with extremely valuable collections of prehistoric antiquities, coins, paintings, sculptures; the principal theatres; the Academy of the Fine Arts (1735); the barracks; the Hop Garden, with the Royal Library (1870–76), 250,000 vols. and 8000 MS., and with the statue (1885) of Linnæus; the Academy of Sciences (1739), with natural history collections; the Museum of Northern Antiquities (1873); the Observatory; and technological, medical, *slöjd*, and other schools. Ship Island (*Skeppsholm*), immediately east of 'the Town' island, is the headquarters of the Swedish navy, and is built over with marine workshops, shipbuilding-yards, &c., and is connected with a smaller island on the south-east, that is crowned with a citadel. Beyond these again, and farther to the east, lies the beautiful island of the Zoological Gardens (*Djurgård*). Immediately south of 'the Town' island is the extensive district of Södermalm, the houses of which climb up the steep slopes that rise from the water's edge. Handsome bridges connect the central islands with the northern and southern districts; besides busses and tramways, the principal means of communication are quick little steamboats, some of which extend their journeys to the beautiful islands in Lake Malar on the west, and eastward towards the Baltic Sea (40 miles distant). Besides the institutions already mentioned Stockholm is the home of the Swedish Academy (1786), Academies of Agriculture (1811), Music (1771), and the Military Sciences (1771), a naval school, a school of navigation, of pharmacy, &c. There is considerable industry in the making of sugar, tobacco, silks and ribbons, candles, linen, cotton, and leather, and there are large iron-foundries and machine-shops. The water approaches to the city are in general rendered inaccessible by ice during three or four months every winter; but to remedy this defect it is proposed to build a new harbour at Nynäs on the Baltic shore, 30 miles to the south. In spite of the winter drawback Stockholm is the seat of a trade sufficient to bring an average of 1760 vessels of 635,000 tons into the port every year, carrying principally grain (wheat and rye), rice, flour, herrings, oils and oilcake, cork-wood, groceries, metals, and wine and spirits (imports). The commodities exported consist chiefly of iron and steel, oats, and tar. Although Stockholm was founded by Birger Jarl in 1255, it was not made the capital of Sweden until comparatively modern times. Since then, however, it has grown rapidly: pop. (1800) 75,500; (1850) 93,000; (1870) 136,000; (1890) 246,151. The principal events in the history of the city have been the sieges by Queen Margaret of Denmark (1389), the battles in the vicinity against the Danes towards the end of the 15th century, the capture of the place by Christian II. of Denmark in 1520, and the Blood Bath he executed amongst the principal men of the country in what was then the Great Market.

Stockmar, Christian Friedrich, Baron, diplomatist, was born of Swedish descent at Coburg, 22d August 1787, studied medicine, and after some service with the army was appointed physician to Prince Leopold of Coburg, ere long to become his secretary and most influential adviser on all questions personal and political. As such he came to England with Leopold when he became the husband of the Princess Charlotte; and he gave Leopold valuable support in the negotiations that issued in making him king of Belgium. He had been ennobled in 1821, and was made a baron in 1831. Leaving Leopold's service in 1834, he became the mentor of Prince Albert of Coburg, and was the trusted friend of the young queen of England and her husband, living sometimes in England and sometimes in Coburg. As representative of Coburg in 1848 at the Diet, he supported Prussia's claim to the headship of the German nation. He died at Coburg, 9th July 1863.

See his *Denkwürdigkeiten*, edited by his son (Eng. trans. *Notabilia*, 2 vols. 1872); Juste, *Le Baron Stockmar* (Brussels, 1873); Sir Theodore Martin's *Life of the Prince Consort*; the Greville *Memoirs*; and for a less favourable view, the *Memoirs* of King Leopold's morganatic wife, Caroline von Bauer (Eng. trans. 1884).

Stockport, a parliamentary, municipal, and county borough of East Cheshire, 6 miles SSE. of Manchester and 37 E. of Liverpool. It is built on the slopes of a narrow gorge, where the Tame and the Goyt unite to form the Mersey, which is spanned by the viaduct (1840) of the London and North-Western Railway, 111 feet high and 625 yards long, as well as by several bridges. St Mary's Church was rebuilt in 1817, with the exception of its 14th-century chancel; and Stockport has also a market-hall (1851–61), mechanics' institute (1862), free library (1875), fine technical school (1890), huge Union Sunday school (1806), grammar-school (1487; rebuilt 1832), infirmary (1832), the Vernon Park (1858), containing a museum, and, in St Peter's Square, a statue (1886) of Richard Cobden, who represented the borough from 1841 to 1847. Stockport was the site of a Roman station, and afterwards of a Norman castle, held till 1327 by the Earls of Chester, and taken by Prince Rupert in 1644, soon after which it was demolished by the parliament. In 1745 Prince Charles Edward passed through Stockport, which Bishop Pococke six years later describes as having 'a little manufacture of the Manchester linen, some woollen and ribands, and two silk-mills like those of Derby.' Since then it has grown to be a most important seat of the cotton industry, in spite of the machinery disturbances (1810–20), the strike of 1828–29, when the military were called out, and many persons wounded, the 'Plug Riots' (1840), and the cotton-famine (1861–64). Felt hats are also manufactured, and there are iron and brass foundries, engine and machine shops, breweries, &c. Stockport was constituted a parliamentary borough (returning two members) in 1832, a municipal borough in 1835, and a county borough in 1888. Pop. (1851) 53,835; (1881) 59,553; (1891) 70,253.

See works by Butterworth (1827–28), Earwaker (*East Cheshire*, 1877), and Heginbotham (1877–78).

Stocks, an apparatus of wood much used in former times in England for the punishment of petty offenders. The culprit was placed on a bench, with his ankles fastened in holes under a movable board, and allowed to remain there for an hour or two. The period of their first introduction is uncertain, but in the second Statute of Labourers, 25 Edw. III., 1350, provision is made for applying the stocks to unruly artificers; and in 1376 the Commons prayed Edward III. that stocks should be established in every village. Each parish had in later times its stocks, often close to the church-yard; and, though the last in London (St Clement Danes, Strand) were removed in 1826, many may still be seen in the country. Indeed the punishment was used so late as 1858 at Colchester, 1863 at Tavistock, and 1865 at Rugby. Combined with the stocks was often a whipping-post for the flagellation of vagrants.

Stocks. See NATIONAL DEBT, and STOCK-EXCHANGE.

Stockton, capital of San Joaquin county, California, on a navigable creek connected with the San Joaquin River, 103 miles by railway E. by N. of San Francisco. It contains a convent and the state lunatic asylum, and manufactures ironware, paper, woollens, flour, soap, carriages, farm implements, &c. Pop. (1860) 3679; (1890) 14,424.

Stockton, FRANCIS RICHARD, an American author, was born at Philadelphia, 5th April 1834, was engraver and journalist, and became assistant-editor of *St Nicholas*. He first attracted notice by his fantastic stories for children, which fill several volumes; but he is best known by all classes of readers as author of *Rudder Grange* (1879). Later works are *The Late Mrs Null*, *The Casting Away of Mrs Lecks and Mrs Aleshine*, and *The Dusantes*, *The Hundredth Man*, *The Schooner Merry Chanter* (1890), *The Squirrel Inn* (1891), and many short stories.

Stockton-on-Tees, an important municipal and parliamentary borough and seaport in Durham, situate on the north side of the Tees, 4 miles from its mouth and 11 ENE. of Darlington, 4 WSW. of Middlesborough, and 236 NNW. of London. The broad and handsome High Street is nearly a mile in length; and a new town, South Stockton, in Yorkshire, has sprung up on the south bank of the river, the two being connected by an iron bridge of three arches (1887), which superseded a five-arch stone bridge of 1771, and cost over £80,000. The town has six churches, a Roman Catholic chapel (1842–70) by the elder Pugin, a town-hall, borough-hall (1852), an exchange, a theatre, large recreation grounds, and an extensive park presented by Major Ropner. The Stockton Races, of some mark in the sporting world, are held here annually in August. Shipbuilding, chiefly in iron and steel, is carried on to a great extent; and blast-furnaces, foundries, engine-works, and extensive potteries and ironworks are in operation. Sailcloth, ropes, linen, and diapers were at one time the staple industry of the town; but their manufacture has been discontinued; and there are breweries, corn-mills, and spinning-mills. The exports are chiefly iron and earthenware; the imports corn, timber in deals, spars, &c., and bark. The Stockton and Darlington Railway, the first to commence passenger traffic, was opened for the double purpose of the conveyance of passengers and goods, September 27, 1825. At Stockton the Tees is navigable for vessels of large tonnage; the navigation of the river has been much improved, and great facilities for an extensive trade provided. Pop. (1831) 7763; (1861) 16,483; (1881), 55,457; (1891) 68,895, of whom 49,731 were within the municipal boundary. Stockton suffered severely from the incursions of the Scots in the early part of the 14th century, but even at that time it enjoyed considerable trade. Its moated castle was taken for the Parliament in 1644, and 'slighted and dismantled' in 1652, almost the last vestige being removed in 1865. At the Restoration it had only 120 houses, mostly built of clay. Since 1867 it sends one member to parliament. Ritson was a native.

See works by J. Brewster (1829), H. Heavisides (1865), and T. Richmond (1868).

Stoddard, RICHARD HENRY, American poet, was born at Hingham, Massachusetts, in July 1825, attended schools in New York, and then worked in an iron-foundry for some years, meanwhile reading widely, especially in poetry. In 1849 he produced a small volume of poems, only to suppress it afterwards; but 1852 saw the birth of a sturdier collection. From 1853 to 1870 he served in the New York custom-house, in 1870–73 was clerk to General McClellan, and for a year city librarian; and he has done much reviewing and writing for the booksellers. His poems include *Songs in Summer* (1857), *The King's Bell* (1862), *The Book of the East* (1867), and *Lion's Cub* (1891).

Stoicism, a school of ancient philosophy, strongly opposed to Epicureanism in its views of human life and duty. The Stoical system dates from the end of the 4th century B.C.; though commonly said to have been derived from the system of the Cynics, it is noteworthy that few of its founders or early apostles were born in Greece; it is the joint produce of Hellas and the Orient, and it was in Rome rather than in Greece that it most profoundly influenced civilisation.

The founder of the system was Zeno, from Citium in Cyprus (340–260 B.C.), who derived his first impulse from Crates the Cynic. He opened his school in a colonnade called the *Stoa Poikilē* ('Painted Porch') at Athens, which was adorned with pictures of the Trojan war, Marathon, and the Amazons by Polygnotus; hence the name of the sect. Zeno had for his disciple Cleanthes, from Assos in the Troad (300–220), whose *Hymn to Jupiter* is the only fragment of any length that has come down to us from the early Stoics—a poem setting forth the unity of God, his omnipotence, and his moral government. Chrysippus, from Soli in Cilicia (280–207), followed Cleanthes, and in his voluminous writings both defended and modified the Stoical creed. Antiquity gave by far the most important position to Chrysippus: 'Without Chrysippus there had been no Porch;' recent German criticism has done much to discover how much of the system is due to each. And Pearson sums up his elaborate investigation as follows: 'The result of our investigation has been to show conclusively that all those doctrines which are most characteristic of the true essence of Stoicism were contributed by Zeno and Cleanthes. To Zeno belong the establishment of the logical criterion, the adaptation of Heraclitean physics, and the introduction of all the leading ethical tenets. Cleanthes revolutionised the study of physics by the theory of tension and the development of pantheism, and by applying his materialistic views to logic and ethics brought into strong light the mutual interdependence of the three branches. The task of Chrysippus was to preserve rather than to originate, to reconcile inconsistencies, to remove superfluous outgrowths, and to maintain an unbroken line of defence against his adversaries.' These three represent the first period of the system. The second period (200–50) embraces its general promulgation, and its introduction to the Romans. Chrysippus was succeeded by Zeno of Sidon, and Diogenes of Babylon; then followed Antipater of Tarsus, who taught Panætius of Rhodes, who, again, taught Posidonius of Apamea, in Syria. Posidonius was acquainted with Marius and Pompey, and taught Cicero; but the moral treatise of Cicero, *De Officiis*, is derived from a work of Panætius. The third period of Stoicism is Roman. In this period we have Cato the Younger, who invited to his house the philosopher Athenodorus; and, under the Empire, the three Stoic philosophers whose writings have come down to us—Seneca, Epictetus, and the Emperor Marcus Aurelius. Stoicism prevailed widely in the Roman world, although not to the exclusion of Epicurean views.

The leading Stoical doctrines are given in certain phrases or expressions, as 'life according to nature,' the ideal 'wise man,' 'apathy,' or equanimity of mind, the power of the 'will,' the worship of 'duty,' the constant 'advance' in virtue, &c. But the system will be best considered under four heads—the Theology; the Psychology; the theory of the Good; and the scheme of Virtue.

(1) The Stoics held that the universe is governed by one good and wise God. According to Epictetus, God is *the father of men*; Marcus Aurelius exults in the beautiful arrangement of all things. They did not admit that the Deity intermeddled in the smaller details of life; they allowed that omens and oracles might be accepted as signs of the foreordained arrangement of God. They held this foreordination even to the length of fatalism, and made the same replies as have been given in modern times to the difficulty of reconciling it with Free-will. God is the author of all things except wickedness; the very nature of good supposes its contrast evil, and the two are inseparable, like light and dark; in the enormous extent of the universe some things must be neglected; when evil happens to the good, it is not as a punishment, but as connected with a different dispensation; parts of the world may be presided over by evil demons; what we call evil may not be evil. Like most other ancient schools, the Stoics held God to be corporeal like man; body is the only substance; nothing incorporeal could act on what is corporeal; the first cause of all, God or Zeus, is the primeval fire, emanating from which is the soul of man in the form of a warm ether. Their theory of the universe may in fact be described as a materialistic pantheism. It is for human beings to recognise the universe as governed by universal law, and not only to raise their minds to the comprehension of it, but to enter into the views of the Creator, who must regard all interests equally; man should be, as it were, *in league* with Him, merge self in the universal order, think only of that and its welfare. By this elevation of view we are necessarily raised far above the consideration of the petty events befalling ourselves. The grand effort of human reason is thus to rise to the abstraction or totality of entire nature. The Stoics held the theory of the *absorption* of the individual soul at death into the divine essence; but, on the other hand, their doctrine of advance and aspiration is what has in all times been the main natural argument for the immortality of the soul. For the most part they kept themselves undecided as to immortality, giving it as an alternative, but reasoning as to our conduct on either supposition, and submitting to the pleasure of God in this as in all other things. In arguing for the existence of divine power and government they employed what has been called the argument from design.

(2) As to the constitution of the mind, they held that men have bodies like animals, but reason or intelligence like the gods. Animals have instinctive principles of action; man alone has a rational, intelligent soul. According to Marcus Aurelius, we come into contact with Deity by our intellectual part, and our highest life is thus the divine life. But the most important Stoical doctrine respecting the nature of man is the recognition of reason as a superior power or faculty that subordinates all the rest—the governing intelligence. This, however, is not a mere intellectual principle, but an active force, uniting intellect and will. The bodily sensibilities are opposed to this higher reason and will, which, however, is strong enough to control them. Another way of expressing the same view was the power of the mind over the body, which was dwelt upon by Epictetus in the most exaggerated form. (The assertion of a doctrine so obviously contrary to the fact as that sickness may affect the body without enfeebling the mind could only end in practical failure, or else in contradiction.) In Seneca we find something very closely approaching to the Christian doctrine of the corruption of human nature. The littleness of humanity was a favourite theme of Marcus Aurelius, and naturally followed from the Stoical mode of contemplating the universe at large. The doctrine called the freedom of will may be said to have originated with the Stoics, although with *them it was chiefly a rhetorical mode of expressing* the dignity of the wise man, and his power of rising superior to circumstances. To prepare the way for the Stoical precepts Epictetus distinguished between things in our power and things not in our power. The things in our power are our opinions and notions about objects, and all our affections, desires, and aversions; the things not in our power are our bodies, wealth, honour, rank, authority, &c. Wealth and high rank may not be in our power, but we have the power to form an *idea* of these—viz. that they are unimportant, whence the want of them will not grieve us. A still more pointed application is to death, whose force is entirely in the idea.

(3) The Good was not by the Stoics identified with happiness. Happiness is not necessary, and may be dispensed with, and pain is no evil. Pains are in a sense an evil, but, by a proper discipline, may be triumphed over. They disallowed the direct and ostensible pursuit of pleasure as an end (the point of view of Epicurus), but allured their followers partly by promising them the victory over pain, and partly by the lofty enjoyments that grew out of their plan of life. Pain of every kind, whether from the casualties of existence or from the severity of the Stoical virtues, was to be met by a discipline of endurance. Great stress was laid on the instability of pleasure, and the constant liability to accidents; whence we should always be anticipating and adapting ourselves to the worst that could happen, so as never to be in a state where anything could ruffle the mind. Much might still be made of the worst circumstances—poverty, banishment, public odium, sickness, old age. Such a discipline was peculiarly suited to the unsettled condition of the world at the time, when any man, besides the ordinary evils of life, might in a moment be sent into exile, or sold into slavery. Moreover, it is a discipline adapted to a certain class of dispositions existing in all ages—men who prefer above all things 'equanimity' of mind, and would rather dispense with great occasional pleasures than risk their state of habitual composure. Next to the discipline of endurance we must rank the complacent sentiment of pride, which the Stoic might justly feel in his conquest of himself. It was usual to bestow the most extravagant laudation on the 'wise man,' and every Stoic could take this home to the extent that he considered himself as approaching that great ideal. The last and most elevated form of Stoical happiness was the satisfaction of contemplating the universe and God. The work of Marcus Aurelius is full of studies of

nature in the devout spirit of 'passing from nature to nature's God;' he is never weary of expressing his thorough contentment with the course of natural events, and his sense of the beauties and fitness of everything. Old age has its grace, and death is the becoming termination. This high strain of exulting contemplation reconciled him to that complete submission to whatever might befall which was the essential feature of the 'life according to nature.'

(4) The Stoical theory of virtue is implicated in their ideas of the good. The fountain of all virtue is manifestly the life according to nature, as being the life of subordination of self to more general interests—to family, country, mankind, the whole universe. The Stoics were the first to preach what is called 'Cosmopolitanism;' for although, in their reference to the good of the whole, they confounded together sentient life and inanimate objects—rocks, plants, &c., solicitude for which was misspent labour—yet they were thus enabled to reach the conception of the universal brotherhood of mankind, and could not but include in their regards the brute creation. They said, 'There is no difference between Greeks and Barbarians; the world is our city.' Seneca urges kindness to slaves, for 'are they not men like ourselves, breathing the same air, living and dying like ourselves?' The Epicureans declined, as much as possible, interference in public affairs, but the Stoical philosophers all urged men to the duties of active citizenship. Although there had been many good and noble men among the pagans, yet positive beneficence had not been preached as a virtue before the Stoics. They adopted the four cardinal virtues (wisdom, or the knowledge of good and evil; justice; fortitude; temperance) as part of their plan of the virtuous life. Justice, as the social virtue, was placed above all the rest; but most interesting to us are the indications of the idea of beneficence. Epictetus is earnest in his exhortations to forgiveness of injuries. Marcus Aurelius often enforces the same virtue; he contends as strongly as Butler and Hume for the existence of a principle of pure—that is, unselfish—benevolence in the mind. There is also in the Stoical system a recognition of duties to God, and of morality as based on piety. Not only are we all brethren, but also the 'children of one Father.'

The extraordinary stress put upon human nature by the full Stoic ideal of submerging self in the larger interests of being led to various compromises. The rigid following out of the ideal issued in a series of the Paradoxes—viz. that all the actions of the wise man are equally perfect, and that, short of the standard of perfection, all faults and vices are equal; that, for example, the man that killed a cock without good reason was as guilty as he that killed his father. The idea of duty was of Stoical origin, fostered and developed by the Roman spirit and legislation. The early Stoic had two different words for the 'suitable' (*kathēkon*) and the 'right' (*katorthōma*). It was a great point with the Stoic to be conscious of 'advance,' or improvement. By self-examination he kept himself constantly acquainted with his moral state, and it was both his duty and his satisfaction to be approaching to the ideal of the perfect man. The Stoical system has largely tinctured modern ages, in spite of its severity. It has always had a charm as an ideal, even when men were conscious of not realising it. The limitation of wants, the practice of contentment, the striving after equanimity, the hardening of one's self against the blows of fortune are all fundamental maxims with the moralists of later ages; and a qualified form of the subordination of self to the general welfare is an essential part of most modern theories of virtue.

The chief ancient authorities on the Stoics are the writings of Epictetus, Marcus Aurelius, and Seneca, themselves Stoic philosophers, together with notices occurring in Cicero, Plutarch, Sextus Empiricus, Diogenes Laertius, and Stobæus. The completest modern account of the system occurs in Zeller's *Stoics, Epicureans, and Sceptics* (Eng. trans. 1870). See also Sir Alexander Grant in the *Oxford Essays* for 1858; Farrar's *Seekers after God* (1868; 3d ed. 1891); Rev. W. W. Capes, *Stoicism* (1880); J. Jordan, *Stoic Moralists* (1880); Ogereau, *Le Système des Stoiciens* (1885); A. C. Pearson, *The Fragments of Zeno and Cleanthes* (1891); and works cited at AURELIUS, EPICTETUS, SENECA.

Stoke-Poges, a village of Buckinghamshire, 2 miles N. of Slough station. Gray's mother settled here in 1742; the beautiful churchyard is the scene of his *Elegy*, and in that churchyard he is buried. Pop. of parish, 2150.

Stokes, SIR GEORGE GABRIEL, mathematician and natural philosopher, was born August 13, 1819, in Skreen, County Sligo. He entered Pembroke College, Cambridge, in 1837, graduated in 1841 as senior wrangler and first Smith's prizeman, and in 1849 was appointed Lucasian professor of Mathematics. In 1852, the year after his election as a Fellow of the Royal Society, he was awarded the Rumford medal; in 1854 he became secretary, a position which he held till 1885, when he was made president for the succeeding quinquennial period. From 1886 he represented Cambridge in parliament, and in 1889 was created a baronet. His papers deal with some of the most abstruse problems of mathematical physics, and are characterised by a remarkable lucidity of treatment and an unerring sagacity of attack. In several of these he has, by opening new ground, given direction to later investigations by others. Two subjects have mainly engaged his attention. The one is Hydrodynamics, of which he wrote a valuable Report for the British Association in 1846, and in which his own contributions rank amongst the most important of the day. Specially may be noted his investigations on waves and on the effect of fluid friction on solids moving through fluids. Then to the theory of light he has made contributions of great value, his profound paper on the dynamical theory of diffraction (1849) being amongst the most important. He first gave a satisfactory theory of fluorescence and phosphorescence, and as early as 1852 he pointed out clearly the physical basis of Spectrum-analysis (q.v.). In 1884-86 he delivered in Aberdeen the Burnett Lectures on 'Light' (3 vols. 1887), an admirable elementary treatise for non-mathematical readers. His influence in the development of the Cambridge school of mathematical physics can hardly be overestimated. The leaders of the British school of natural philosophy all look to Stokes as their master and model.

See his reprint of *Mathematical and Physical Papers* (vol. i. 1880; vol. ii. 1883). He was Gifford Lecturer on Natural Theology at Edinburgh in 1891-92.

Stokes, WILLIAM (1804-77), physician, studied at Edinburgh, and in 1845 became regius professor of Medicine in Dublin University. He wrote lectures on the *Theory and Practice of Medicine* (1837), and works on the diseases of the chest and of the heart and on continued fevers.—His eldest son, WHITLEY STOKES, born at Dublin in 1830, studied law at Trinity College, went to India in 1863, and after holding a series of important legal appointments was in 1877-82 president of the Indian law-commission and draughtsman of the present civil and criminal codes. He has written many legal works, including *The Anglo-Indian Codes* (vols. i. and ii. 1887-88), and edited a large number of Irish and other Celtic glosses and texts.

Stoke-upon-Trent, a manufacturing town of Staffordshire, the capital of the 'Potteries,' on the Trent and the Trent and Mersey Canal, 15 miles SE. of Crewe, 2 E. of Newcastle-under-Lyme, and 16 N. of Stafford. It is a modern place, dating only from the last quarter of the 18th century, and has a parish church with Wedgwood's grave, a town-hall (1835), a market-hall (1883), a free library (1878), the Minton memorial building (1858), the Hartshill Infirmary (1868), public baths, and statues of Wedgwood, Minton, and Colin Minton Campbell. Its factories of porcelain, earthenware, encaustic tiles, and tesselated pavements are among the largest in the world; and the industries also include coal-mining, brickmaking, and the manufacture of iron, engines, machinery, &c. Mrs Craik was a native. The parliamentary borough, constituted in 1832, was much curtailed in 1885 and lost one of its two members; the municipal borough was incorporated in 1874. Pop. (1871) 15,144; (1881) 19,261; (1891) 24,027; of parliamentary borough (1891) 75,352. See John Ward's *Borough of Stoke-upon-Trent* (1843).

Stolberg, CHRISTIAN, COUNT OF, a poetic writer, was born at Hamburg, October 15, 1748. Whilst a student at Göttingen he identified himself with the Göttingen poetic school (*Dichterbund*), a literary circle embracing also Bürger and Voss. After twenty three years' public service in the duchy of Holstein he retired, and died at his seat of Windebye, near Eckernförde in Sleswick, on January 18, 1821. As a poet he was inferior in genius to his brother Friedrich Leopold, in whose books his own work was generally included. His principal productions are *Gedichte* (1779), *Gedichte aus dem Griechischen* (1782), *Schauspiele mit Chören* (1787), *Vaterländische Gedichte* (1810), and a metrical translation of Sophocles (1787).

Stolberg, FRIEDRICH LEOPOLD, COUNT OF, younger brother of the preceding, was born at Bramstedt in Holstein on November 7, 1750. Like his brother he was one of the *Dichterbund* fraternity at Göttingen. Most of his active life was spent in the public service of Denmark. Although possessed of some degree of poetic fancy, he was on the whole a somewhat colourless writer in the style of Klopstock. Shortly after the outbreak of the French Revolution he went over to the Roman Catholic Church, and from that time a very pronounced religious and ascetic temper made itself prominent in his writings, of which the principal was *Geschichte der Religion Jesu Christi* (15 vols. 1807-18). He died on his estate of Sondermühlen, near Osnabrück, 5th December 1819. Besides the volumes of *Gedichte*, *Schauspiele*, *Vaterländische Gedichte*, issued along with his brother's works, F. L. Stolberg published translations from Æschylus, Plato, and the *Iliad*, an idyllic romance *Die Insel* (1788), and other books. See works by Menge (1863), Hennes (1876), and Janssen (3d ed. 1882).

Stole (Gr. *stolē*, Lat. *stola*, 'a robe'), a narrow vestment, of the same stuff as the chasuble, worn by bishops and priests in the Latin Church during mass, in the administration of sacraments, and in certain blessings, and by deacons when they have to move the blessed sacrament. In some places it is worn while preaching. Bishops wear it over both shoulders; so also do priests, but crossed over the breast; deacons wear it over the left shoulder. It is also used in some cases as a symbol of jurisdiction, in which sense it is constantly worn by the pope, even when not officiating. In the Anglican Church the stole is worn with the same difference by priests (but not crossed) and deacons. It is usually of black silk, fringed at the ends, with sometimes crosses embroidered; but coloured stoles, according to the season, are also worn in some churches. In the Greek Church the stole proper is peculiar to deacons; among Syrian Christians it is worn by clerics of all (even minor) orders. The stole originated in the *orarium* or handkerchief, which was sometimes worn as a scarf, and which in the 6th and 7th centuries came to be recognised as a sacred vestment in the Western Church. The name stole began to be substituted by the 9th, and was the common word before the 12th century. See illustrations at CHASUBLE and COPE. *Stole-fees* are the same as surplice-fees (see SURPLICE). The broad scarf is worn by chaplains to any member of the royal family, or to any peer or peeress, doctors in divinity, and capitular members of a collegiate church.

Stolen Goods are thus treated by English law: a *bonâ-fide* purchaser of such goods, who has not bought them in market overt, is bound to restore them to the true owner; but if the goods are sold in market overt, the purchaser is entitled to keep them unless the owner has duly prosecuted and convicted the thief. Market overt means the open market in towns and places where a legal market is held. In the City of London every shop is held to be a market overt, but this only applies to the City proper (see SALE). The above rule as to stolen goods does not apply to valuable securities which are stolen, if the security has been paid or discharged *bonâ fide* by the person liable, or if the security is a negotiable instrument, and it has passed to a 'holder in due course' (Bills of Exchange Act, 1882, sect. 29). It is a punishable offence to offer or take rewards for the recovery of stolen property. See also THEFT. The Scots law does not recognise the doctrine of market overt.

Stolp, a town in the Prussian province of Pomerania, stands on the river Stolp, 85 miles W. by N. of Danzig, and has a castle, some old churches (the castle chapel dating from the 13th century), iron-foundries, machinery, and amber manufactures, and an active trade in agricultural products, timber, fish, &c. Pop. 23,837.

Stomach. The Anatomy and Physiology of this organ are treated of in the article DIGESTION (q.v.). See also ABDOMEN, ARTIODACTYLA, BIRD, FISHES, &c.; and INDIGESTION, VOMITING.

DISEASES OF THE STOMACH.—Acute *gastritis*, or inflammation of the mucous membrane of the stomach, is a very rare disease, except as a result of the administration of an irritant poison; during six years' experience at La Charité (one of the leading Parisian hospitals) Dr Louis made notes of 6000 cases of disease, but did not meet with a single case of fatal idiopathic or spontaneous gastritis. The symptoms which indicate that an irritant poison has been received into the stomach are a gradually increasing sensation of uneasiness or heat, which shortly assumes an acute burning character in the epigastric region. This pain is accompanied with vomiting, which becomes increasingly frequent as the pain augments, and often with hiccup. There is usually extreme tenderness on pressure, and the patient bends his body forward to relax the muscular tension. During the accession of these symptoms there is a marked degree of excitement, as indicated by the acceleration of the pulse and breathing and the heat of the skin. This condition is, however, soon exchanged for one of prostration. The skin becomes cold and clammy, the pulse thready and feeble, and the breathing catching and intermittent; until finally, after a variable period of exhaustion, the patient sinks, usually retaining his mental faculties to the last. Although the above-described symptoms are always more or less present, each irritant poison occasions some special symptom and some characteristic lesion; and the period at which death ensues varies for different poisons.

Sub-acute gastritis, or *gastric catarrh*, is by no means a rare affection, and it occurs in two distinct forms—'one in which the malady is caused by a constitutional state, the effects of which are shown in a variety of other organs as well as in the stomach; another in which it is due to causes connected chiefly or exclusively with this organ, which is submitted to an irritative process somewhat analogous to that typified by the gastritis of irritant poisoning' (Brinton, *On Diseases of the Stomach*). The first of these forms is well illustrated in such diseases as smallpox, scarlatina, pneumonia, &c., in which the digestive process is much interfered with, and after death distinct marks of inflammation are seen in the stomach. The other variety, which is often of a chronic form, is well seen in cases of delirium tremens, the affection being sub-acute or chronic, according as it has been produced by a single prolonged debauch, or by a protracted habit of drinking spirits, and the patient's final malady being induced by a deficiency of food or some injury or acute disease. Purely chronic inflammation may be induced by various causes, of which the most common are the abuse of alcoholic drinks, habitual excess in eating, the eating of indigestible food, and the excessive use of irritating medicines. The symptoms are like those of indigestion in a severer form; in fact it is impossible to draw a sharp line of distinction between the two affections.

The treatment of gastritis varies much with each individual case, but the first point is the removal of the cause—to be attempted in cases of irritant poisoning either by the removal of the poison (by the stomach-pump or emetics, as, for example, sulphate of zinc) or by its neutralisation by means of an antidote. In very severe cases leeches may be applied to the epigastrium; but counter-irritants, such as turpentine on a hot moist flannel, or mustard-poultices, are generally of more service. Continuous fomentation with water, as hot as can be borne, often gives great relief, while at the same time iced water, or small lumps of ice swallowed whole, usually relieve the thirst and mitigate the pain. Enemata of purgative materials, if the bowels are constipated, or of a soothing character (as thirty drops of laudanum in a little starch or gruel), if the bowels are irritable, may be prescribed with advantage. When the stomach begins to be able to retain food, it must be given in the form of a bland liquid, in small doses, at distant intervals. Chronic gastritis must be treated in much the same manner as Indigestion (q.v.). The most essential point of treatment is the due regulation of the diet.

Ulcer of the stomach is the most important of the idiopathic diseases of that organ, both from its frequency, from the facility with which it may in some cases be detected during life, from the fact that at any period of its protracted course it may prove suddenly fatal, and from its being usually curable. The first and most characteristic symptom of this disease is pain, which comes on very soon after the ingestion of food, and lasts for an hour or two; vomiting often ensues, with such relief that the sufferer sometimes gets into the habit of inducing it himself. The place of most common appearance and greatest intensity of the pain is the centre of the epigastric region, but it is sometimes higher, lower, or to one side, and occasionally in the back. The pain in both the epigastric and the dorsal region is almost always much increased by pressure; also by food and drink, especially by the ingestion of hard and indigestible substances. The pain, vomiting, and want of nourishment lead of course to much enfeeblement. The disease is sometimes terminated by the occurrence of perforation, ending in rapidly fatal peritonitis; and if this accident does not occur, the dyspeptic symptoms may become complicated by hæmorrhage from the stomach, sometimes so rapid that it distends the stomach and adjacent small intestine with a single gush, and causes fainting and almost immediate death, but more commonly occurring as a slow and intermittent drain of blood, giving rise to anæmia. In some cases, however, symptoms are either absent altogether or so slight that no attention is paid to them, till the presence of the ulcer is revealed by one of these accidents. If death from the above causes (inanition, perforation, or hæmorrhage) does not terminate the disease, the symptoms frequently subside in something like the inverse order in which they occurred, and recovery, often after many years' suffering, ensues. Brinton states that this lesion may be detected in (on an average) 5 per cent. of persons dying from all causes; that it occurs twice as frequently in females as in males, and that it is specially a disease of middle and advancing life—twenty-seven being the average age in females and forty-two in males. Nothing is known with certainty regarding the causes of this disease, except that advancing age, privation, mental anxiety, and intemperance so frequently coincide with it that they may be regarded in some degree as producing it. But it is particularly frequent as a complication of Chlorosis (q.v.). In relation to treatment strict attention to diet is of the first importance. When the symptoms are urgent the patient should maintain the recumbent position, and should be fed on cold or lukewarm milk thickened with biscuit-powder, given in doses of one or at most two tablespoonfuls at regular intervals of from ten minutes to an hour. The pain is often relieved by the application of a mustard-poultice or blister to the painful spot; and benefit is frequently derived from the internal administration of bismuth (in doses of ten grains), either given alone or combined with the compound kino powder (in five-grain doses). When there is hæmorrhage small lumps of ice may be swallowed; and if all food is rejected by vomiting, nutrient injections must be thrown into the lower bowel. Aperients are sometimes required, but they must be given with caution; and if castor-oil can be taken without increasing the pain or vomiting, it is the most harmless remedy of its class.

Cancer of the stomach is obscure in its symptoms, frequent in its occurrence, and always fatal in its termination. The typical course of this disease is thus sketched by Brinton: 'An elderly person perhaps hitherto free from dyspepsia begins to suffer from a capricious, and soon a diminished appetite, which is by-and-by associated with occasional nausea, or even vomiting, and with a sense of uneasiness or distention of the stomach. His complexion, already pale and unwholesome, next acquires a muddy, yellowish, or faint greenish hue. His gastric symptoms now increase; often by a sudden and marked augmentation, which corresponds to what is in other cases their first appearance. Vomiting, if already present, becomes more frequent and urgent; local uneasiness deepens into pain; and both these symptoms are excited or increased by taking food. At a somewhat later period hæmorrhage generally occurs, usually but scanty in amount, and therefore depending to a great extent on casual circumstances for its detection. About this time a tumour often becomes perceptible near the middle of the epigastric region of the belly. As the local symptoms increase the cachexia of the patient also augments, and is evidenced not only by the colour already mentioned, but also by debility and emaciation, and at last by prostration, which ends in anasarca, delirium, and death.' But any or all the distinctive symptoms may be absent. 'There are indeed some cases in which the most acute observer cannot do more than suspect the presence of the disease.' In the treatment of this formidable disease more good is done by careful attention to the diet than by any medicine. Good milk or strong beef-tea thickened with biscuit-powder may be given in the same manner as recommended in ulcer; and milk mixed with a little old Jamaica rum will sometimes stay on the stomach when everything else is vomited. If there be pain, opiates must be administered, either in the ordinary way, as enemata, or hypodermically, the latter having the advantage of having less tendency to induce constipation.

Hæmatemesis, or *Vomiting of Blood*, is a serious and important symptom of disease affecting the stomach. It may occur by the ulcerative destruction of the walls of a comparatively large blood-vessel in gastric ulcer and in cancer; but it generally is of the kind termed capillary, and happens under various circumstances, of which the following are the principal. It may take the place of some habitual hæmorrhage, or, in other words, be vicarious. Thus, it may possibly take the place of the menstrual discharge. It is often caused by disease or injury of the stomach; for example, it frequently occurs after the ingestion of strongly irritant poisons, or even an immoderate dose of alcohol into the stomach. It may be a consequence of disease in adjacent viscera, occasioning an overloading of the veins of the stomach—e.g. enlargement of the spleen, obstruction of the portal circulation depending on disease of the liver, enlargement of the uterus in the advanced periods of pregnancy. It may result from changes in the composition of the blood, such as occur in scurvy, purpura, and yellow fever. The treatment must be directed against the disease on which the hæmorrhage depends rather than against the mere symptom; but from whatever cause it arises, if it is proceeding to a dangerous extent the patient should be kept perfectly quiet in bed, and should swallow small pieces of ice. Hot applications may also be applied to the extremities with the view of directing the blood to those parts. The medicines most likely to be of service are acetate of lead, gallic acid, dilute sulphuric acid, and oil of turpentine; but they should only be given on medical authority.

Stomata, minute openings in the epidermis of leaves and tender green stems of plants, and subserve the purpose of respiration (see VEGETABLE PHYSIOLOGY). They are found in parts exposed to sun and light, and hence are most numerous on the *upper* surface in most leaves, on the *under* side of floating leaves, but in some monocotyledons equally distributed. See illustration at LEAF; and for the complex stomata of *Marchantia*, see LIVERWORTS.

Stone, a market-town of Staffordshire, on the left bank of the Trent, 7 miles NNW. of Stafford and 7 S. of Stoke-upon-Trent. It has a town-hall (1869), a market-hall (1868), Alleyne's grammar-school (1558), remains of an Augustinian monastery, two modern convents, and manufactures of earthenware, boots and shoes, beer, leather, &c. Pop. (1851) 3443; (1891) 5754.

Stone, a weight formerly in use throughout the northern countries of Europe, but varying in different countries, and now mostly obsolete. The British imperial stone, the only legal one, is 14 lb.; but in various parts of the country stones of other values are or have been in use, as a stone of 24 lb. for wool, 8 lb. for butcher-meat, 22 lb. for hay, 7 lb. for oatmeal in Scotland, 16 lb. for cheese, 32 lb. for hemp, and 5 lb. for glass.

Stone. See CALCULUS, and LITHOTOMY.

Stone. Under the head BUILDING STONE (see also ROADS) the more important kinds of stone used for architectural purposes are noticed, and some of these, such as limestone, marble, sandstone, flagstone, flint, slate, granite, basalt (greenstone), serpentine, and porphyry, are again referred to under their respective names. See under MILL, OVEN, and WHETSTONES for millstones, firestone (leckstone), and hones. Purely ornamental stones other than gems are noticed under ALABASTER, FLUOR SPAR, JADE, JASPER, LABRADORITE, LAPIS LAZULI, MALACHITE, and other heads. The beautiful material called Mexican onyx marble (stalagmitic aragonite) has only been known for a few years. Algerian onyx marble, also a handsome stone, wants the bright-coloured veins of the Mexican. The most recent addition to these ornamental stones is the jasperised wood of Arizona, many pieces of which are of striking beauty. In recent years some beautiful porphyries and granites from Norway and other countries have been cut and polished for decorative purposes at some of the Aberdeen granite-works. Besides its well-known granites Scotland possesses quite a number of handsome siliceous stones suitable for architectural decoration, hitherto not utilised.

Stone-dressing.—Ashlar stones (see MASONRY), whether of limestone or sandstone, after being chiselled on the face, generally get the tool-marks removed by smoothing them with a bit of soft sandstone and water. In England a stone so finished is technically said to be *rubbed;* in Scotland, *polished.* It has recently become the custom in Scotland, where sandstone is the only freestone, to dispense with the 'polishing' and leave irregular chisel-marks visible. In former years there were in use various effective ways of dressing stones for the fronts of buildings. One of these was *tooling* or *droving*—i.e. covering the face with small flutings by means of a broad chisel; another was *broaching* or incising the face with narrow parallel grooves by the use of a pointed tool. Many buildings of a by no means unpretentious kind recently erected in Scotland and elsewhere have their ashlar stones dressed only on their beds and joints, their faces being merely 'pinched' from the edges, leaving the exposed part of the stones rough and hackly. When the face of granite is not polished it is generally dressed with a nidging hammer, which gives it a chiselled appearance.

Preservation of Stone.—The preservation of stone can be effected to a great extent by coating the surface with boiled linseed-oil, or with oil-paint; but these methods are not much in favour, as they destroy the crystalline appearance which constitutes the beauty of most natural stones. There is, however, no other efficient way known of preserving a sandstone with a tendency to decay. More hope may be entertained that certain chemical solutions will prevent the wasting of oolitic and magnesian limestones so much used as building stones in London and southern England generally. The coating of these with an alkaline silicate and the subsequent application of calcium chloride, as proposed by Ransome, has not had the beneficial result which was expected from this treatment. Quite recently the owners of the Bath stone (oolitic) quarries have recommended a preserving solution under the name of 'Fluate.' The exact nature of this material does not appear to have been disclosed, but in October 1890 *The Builder* published analyses of the stone before and after being fluated. It may be inferred from these analyses that its durability is increased by the application of this fluid to its surface, but there can be no certainty till the treatment is tested by time. The preservation from decay of a porous substance like freestone (whether sandstone or limestone) in a climate like that of northern Europe is a problem of the greatest difficulty. One precaution ought never to be neglected, and that is to see that a 'damp-proof course' is put through the walls of a building just above the ground, to prevent the ascent of moisture from the soil. See BUILDING.

Artificial Stone.—Burnt clay in the form of bricks or terra-cotta blocks of larger size, though not usually classed as artificial stone, is by far the best substitute for real stone. Portland Cement, (q.v.) mixed either with sand alone or with sand and broken stones, forms one kind of artificial stone (see CONCRETE). In the north of Italy paving tiles with beautiful patterns are made by inlaying Portland cement with small pieces of marble, serpentine, and other ornamental stones. This kind of work is obviously suited for external wall decoration of a very effective kind, provided that even the best Portland cement has the durability which some of its advocates claim for it. Scagliola (q.v.) is a polished plaster for internal decoration, somewhat similarly ornamented. Von Fuchs of Munich, Kuhlmann of Lille, and Ransome of Ipswich have successively done material service in enabling an artificial stone to be made of the silicate of soda or potash (soluble glass) and sand (see GLASS, Vol. V. p. 245). Ransome's artificial stone is a hard substance formed by mixing sand with a solution of this alkaline silicate, then pressing it into moulds, and when partially dry soaking it in a bath of chloride of calcium, which to some extent penetrates the 'stone,' forming the insoluble silicate of lime (calcium silicate). Chimney-pieces, vases, and architectural ornaments of various kinds have been made of this material. Ransome's 'patent concrete stone' is made in the same way, with broken pieces of stone added.

Stone Age, or AGE OF STONE, is a term used in archæology to denote the condition of a people using stone as the material for the cutting tools and weapons which, in a higher condition of culture, were made of metals. The expression 'age,' when used in this connection, is not therefore significant of a fixed period in chronology, but implies merely the time, longer or shorter, earlier or later, during which the condition subsisted. The duration of such a condition must necessarily have varied from various causes in different areas, and chiefly in consequence of contact with higher degrees of culture. Populations placed in remote situations, and on that account remaining uninfluenced by such contact—like the islanders of the South Pacific and the Eskimos of the extreme north for instance—have remained in their stone age to the 19th century. On the other hand, the populations of the European area, in portions of which there were successive centres of high culture and civilisation from a very early period, had all emerged from their stone age, through the use of bronze, many centuries before the Christian era. The progress of early culture in Europe seems to have been from the south and east, northward and westward, so that the emergence of the different populations from their age of stone was accomplished much earlier in southern and eastern Europe than in its northern and western parts. But while the stone age of different areas is thus not necessarily synchronous, it seems to be true of all European areas that this is the earliest condition in which man has appeared upon them. Our knowledge of the details of the archæology of Asia, Africa, and America is still too limited for general conclusions to be drawn with certainty, but the existence of similar prehistoric conditions, as regards the use of stone prior to the introduction of metals in Asia Minor, India, China, Japan, the northern parts of Africa, and many parts of North and South America, has been fully established. There are no data by which the period of the early stone-using populations of Europe can be defined, even approximately. But in England, Belgium, and France, and across the Continent to the shores of the Mediterranean, they were contemporary with animals which are now either wholly or locally extinct, such as the mammoth, woolly rhinoceros, cave-lion, cave-bear, and hyæna, the reindeer, musk-ox, and urus. It is an open question to what extent this change of fauna implies a change of climate, but from the geological conditions in which the flint implements of the earliest types are found it is evident that, though extensive changes must have taken place since they were deposited in the river-basins, they belong exclusively to the later deposits of the Quaternary period.

The stone-age implements of Europe have been divided into two classes—the *palæolithic* or older stone implements and the *neolithic* or newer stone implements. This is equivalent to dividing the stone age of Europe into two periods, earlier and later, as the palæolithic implements are found associated with the extinct and locally extinct fauna, while the neolithic implements are found associated with the existing fauna. The palæolithic stone implements are distinguished as a class from the neolithic by their greater rudeness of form, and by the facts that they are exclusively of flint and have been manufactured by chipping only. The neolithic stone implements on the other hand are of finer forms, often highly polished, and made of many varieties of stone besides flint (see fig. 4). But the mere fact of an implement having been fashioned by chipping alone is not decisive of its palæolithic character, because certain varieties of implements of neolithic time still continued to be made by chipping only. The distinguishing differences are the typical forms and the circumstances of association in which the implements are found.

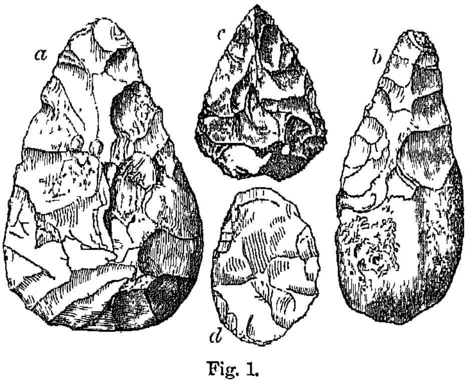

Fig. 1.

a, round-pointed, tongue-shaped implement, Biddenham, near Bedford; *b*, acutely-pointed implement made from rounded nodule of flint, St Acheul, near Amiens; *c*, from Bemerton, Wilts; *d*, irregularly-ovate, sharp-rimmed instrument, Moulin Quignon, Abbeville. (From Evans's *Ancient Stone Implements of Great Britain.*)

Palæolithic stone implements are found *in situ* in river-gravels, in caves, and in association with bones of the extinct animals before mentioned. Neolithic stone implements are found in the surface-soil, in refuse-heaps of ancient habitations, and in chambered tombs. Implements of bone or deer-horn of both periods are similarly distinguished by their typical forms and their circumstances of association. The palæolithic implements of flint are mostly so rude in form and finish that it is impossible to apply to them names indicative of specific use (see fig. 1). They are roughly chipped and destitute of that secondary working of finer character along the sides and edges which gives finish to the forms of the neolithic types. They present, however, a considerable number of well-marked typical forms. Those from the river-gravels are chiefly flakes, trimmed and untrimmed, for cutting and scraping; pointed implements, some almond-shaped or tongue-shaped; and more obtusely pointed implements, with rounded and often undressed butts. There is also a series of scraper-like implements, and another of oval sharp-rimmed implements, which are more carefully finished than most of the other varieties. The flint implements from the caves present a greater variety of form. They are generally characterised by secondary working, and are therefore much more carefully finished, often in many respects approaching closely to neolithic types. From the caves also come a series of implements of bone and of carvings on bone which have excited much astonishment on account of the extraordinary contrast between their artistic character and the extreme rudeness of many of the implements of stone with which they are associated (see fig. 2). These bone implements consist of well-made needles, borers, javelin or harpoon points barbed on one or both sides, and implements of reindeer-horn of unknown use (called by the French archæologists *batons de commandement*), which are usually carved in relief or ornamented with incised representations of animals, and occasionally of human figures. The animals, as for instance a group of reindeer from the cave of La Madelaine, Dordogne, are drawn with wonderful faithfulness, freedom, and spirit. In another instance, engraved on a flat piece of mammoth-tusk is an outline representation of that animal showing its characteristic elephantine form and the covering of hair peculiar to the species. The neolithic stone implements consist of axes and axe-hammers, knives, daggers, spear and arrow heads (fig. 3), saws, chisels, borers, and scrapers. The axes and axe-hammers are made of many varieties of stone besides flint. Some of the finer polished axes are of jade and fibrolite. The jade axes were once thought to have been importations from eastern Asia (see JADE), but the chippings of their manufacture have been found in the lake-dwelling sites of the Lake of Constance, and jade itself was discovered about 1887 *in situ* at Jordansmuhl near Breslau in Silesia. The axes are mostly imperforate. They are simple wedges, the butt end of which was inserted in the shaft, or in a socket of stag's-horn with a tenon on the upper end mortised into the shaft, though the shaft was sometimes put through a hole in the stag's-horn socket. The perforate stone axes, or axe-hammers, which belong to the close of the stone age, had the hole for the shaft bored through them by a cylinder of wood or bone, working with sharp sand and water. Most of the other implements were made only of flint, and generally finished by chipping, without being ground or polished. Some of the long Danish knives and daggers (fig. 5) are marvels of dexterous workmanship, on account of the thinness of the blade, and the straightness and keenness of the edge, produced by the mere process of chipping or removing successive flakes from the surface.

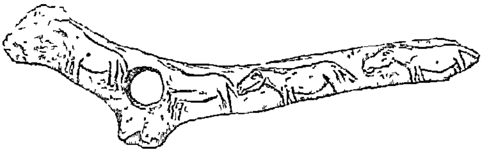

Fig. 2.—Carved Reindeer-horn, Laugeriebasse, Dordogne. (From Cartailhac's *La France Préhistorique.*)

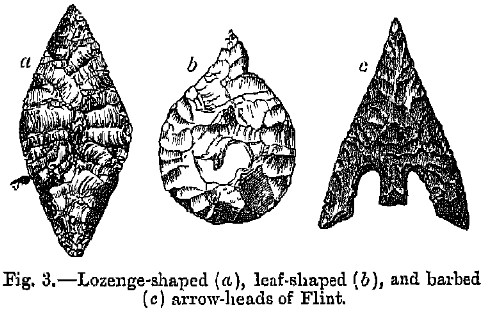

Fig. 3.—Lozenge-shaped (*a*), leaf-shaped (*b*), and barbed (*c*) arrow-heads of Flint.

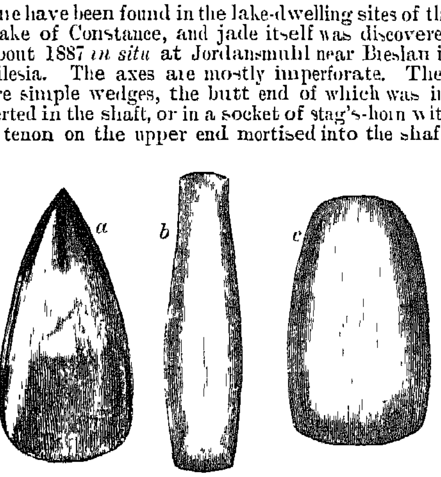

Fig. 4.—Polished Stone Axes or Celts: *a*, 5½ inches; *b*, 13 inches; *c*, 5 inches long.

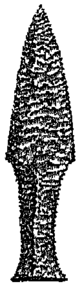

Fig. 5. Danish Flint-dagger.

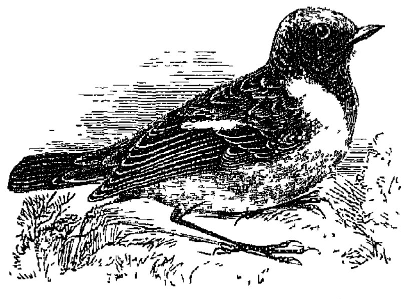
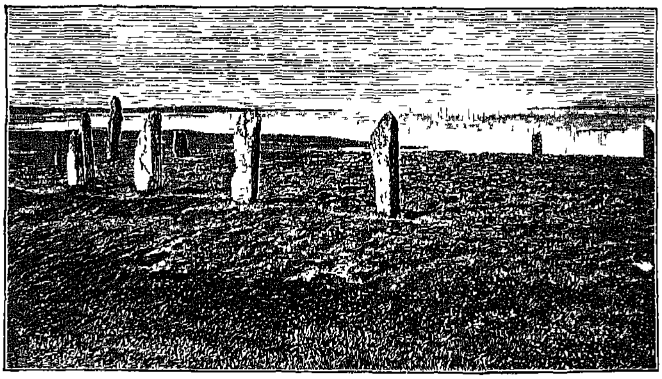
The burial customs of the stone age included both inhumation and cremation, the former being, however, the earlier method. No burials of the river-drift period have yet been discovered. The cave-dwellers of the stone age buried their dead in cavities of the rocks like that of Cro-Magnon in Dordogne, in which four or five skeletons were found huddled together, without being enclosed in cists or accompanied by sepulchral pottery. From a comparison of the remains from such cave-cemeteries in different localities it has been concluded that even at this early period Europe was already occupied by more than one race of men. The populations of the neolithic time deposited their dead, with or without previous cremation, in or on the floors of the chambers of dolmens, or great chambered cairns. The sepulchral pottery accompanying these burials, in Britain at least, is generally of a hard-baked dark-coloured paste, the form of the vessels mostly basin-shaped and round-bottomed, and the ornamentation entirely composed of straight lines placed at various angles to each other. The implements found with these interments are mostly of the commoner kind, such as flint knives, scrapers, or strike-lights (used with a nodule of pyrites of iron), arrow-heads, and more rarely axes and axe-hammers of flint or polished stone. The neolithic inhabitants of northern and central Europe were not merely nomadic tribes subsisting on the products of the chase; they practised agriculture, and possessed the common domestic animals we now possess. The presence in the refuse-heaps of their seacoast settlements of the remains of deep-sea fishes shows that they must have possessed boats and fishing-lines, as was also the case with the stone-age inhabitants of the Lake-dwellings (q.v.). The estimates that have been made of the antiquity of the stone age in Europe are necessarily very various and all equally conjectural, but it has been considered that the close of the neolithic period or the time when the use of stone began to be superseded by that of bronze in northern Europe cannot have been much later than from 1000 to 1500 B.C. See works cited at ARCHÆOLOGY.

Stone-chat (*Pratincola rubicola;* see CHAT), one of the most common of the British Turdidæ, a pretty little bird, rather smaller than the red-breast, black on the upper parts and throat in summer; the breast of a dark reddish colour; some white on the sides of the neck, the wings, and the tail. It makes its nest of dry grass and moss lined with bents, hair, and feathers on the ground or at the foot of a low bush. It is resident in the British Isles, but a few may migrate southwards in cold winters, when there is also an influx of others from the colder continental regions. It is somewhat local and erratic in its distribution, frequenting a place for a few seasons and then suddenly abandoning it. It feeds on insects, grubs, worms, beetles, and seeds. The Wheat-ear (q.v.) is, however, the true Stone-chat.



Stone-chat (*Pratincola rubicola*).

Stone Circles, or Circles of Standing Stones (q.v.), popularly, but erroneously, called Druidical Circles in Britain, Dom-rings or Thing-steads in Scandinavia, and known as Cromlechs in France, consist of unhewn stones set up at intervals round the circumference of a circular area usually of level ground, though they are sometimes found on the slightly sloping side of a hill. The area thus marked off from the surrounding ground varies in size from less than 20 to more than 100 feet in diameter. The number of stones composing the circle also varies greatly, but as most stone circles exist now in a condition of greater or less dilapidation it is often impossible to ascertain with certainty what the original number may have been. Sometimes they are mere boulders rolled into position, at other times they are pillar-stones, evidently chosen for their length, and wedged upright by smaller stones inserted round their bases in the cavity in the subsoil prepared for their reception. Sometimes there is a single circle only, at other times one or two smaller circles are contained concentrically within the interior circle. Occasionally the area on which the circle stands is further marked off from the surrounding ground by a trench, or by a trench and rampart of earth surrounding the whole, except where a narrow pathway gives access to the interior on the original level. In the district of Scotland between the Dee and the Spey there are numerous examples of a special variety of stone circle distinguished by the presence of a great flat block placed on edge so as to fill one of the intervals between two of the upright pillars, usually on the south-west side of the circle. Circles of small boulder stones placed close together and scarcely showing above the turf are also found in many parts of Europe, indicating that the space thus enclosed has been reserved for burial deposits in prehistoric times. But the circles composed of large stones set at considerable intervals apart are linked with the burial customs of the builders of the chambered cairns of the stone age. A great circle of standing stones encircled the gigantic chambered cairn of New Grange in Ireland, and the smaller cairns of Clava in Strathnairn near Inverness are similarly encircled by pillar-stones. As a rule the cairns which covered the cremation interments of the bronze age are smaller than those of the preceding period, and the custom of placing the burnt bones in a cavity in the soil, covered only by an inverted urn of clay, dispensed with the cairn altogether, while it retained the circle of standing stones as a visible mark or fence of the grave-ground. In about twenty instances in which there has been systematic excavation of stone circles in Scotland the examination of the interior space has disclosed burials of the bronze age, mostly after cremation, but occasionally unburnt. The cremated remains were deposited with cinerary urns placed either in an inverted position over the burnt bones or upright and containing the burnt bones, at the bottom of a shallow pit excavated in the subsoil. These cinerary urns exhibit the forms and ornamentation characteristic of the age of bronze. Sometimes the burials have been placed in cists of unhewn slabs of stone, covered by small cairns of loose stones, underneath the surface level; at other times the burnt bones of many burials have been found placed in shallow cavities excavated in the soil of the interior area of the circle, near the bases of the upright stones. From these circumstances it is conclusively demonstrated that the common varieties of stone circles in Scotland are circular cemeteries of bronze-age burials. It may be that the greater circles, like those of Stennis, Avebury, and Stonehenge, may have had a different origin and purpose, but there is no evidence more conclu-



Stone Circle, Stennis, Orkney.

sive than mere conjecture for the assumption of a different purpose for the larger circles, and the great size of the circle surrounding the immense chambered cairn of New Grange shows that a great circle was associated with sepulture.

The largest of the Scottish stone circles is that of Stennis in Orkney, standing on the slope of the hill overlooking the loch of that name about 4 miles NE. of Stromness. It is surrounded by a trench 30 feet wide and about 6 feet in depth, enclosing a total area of about 2½ acres. The trench is crossed by two accesses to the enclosed area on opposite sides of the circle, each 17 feet wide. The circle of pillar-stones stands 13 feet within the trench on a circumference of 340 feet in diameter. The original number of pillar-stones was probably sixty, of which only thirteen are now standing; ten are prostrate, and the stumps or fragments of thirteen more are still recognisable. The highest stone standing is 14 feet in height, and several of those now prostrate exceed 12 feet in length. The average distance between the stones is about 17 feet. A smaller circle, which seems, however, to have been composed of larger stones, stood about a mile to the south. Its whole interior area is raised about 3 feet above the surrounding level, and has had a circumscribing ditch, with a rampart on the inner side. Only two stones remain standing, and a somewhat larger one, now prostrate, is 19 feet long and 5 feet broad. It was near this circle that the perforated stone stood, through the aperture of which it was the custom in the 18th century for young men and women of the district to plight their troth by joining hands, a promise of marriage thus made being regarded with superstitious reverence as specially binding. The largest stone circle in England is that of Avebury (q.v.) in Wiltshire. This monument is apparently alluded to in a charter of King Athelstan, dated 939 A.D., where one of the boundaries is said to run 'from the road to Hackpen northward, up along the Stone Row, thence to the burying-places.' Stonehenge (q.v.), the most famous of British stone circles, stands within a ditch and embankment enclosing an area of about 360 feet in diameter. It differs from other stone circles not only in its ground-plan, but in the pillar-stones of the exterior circle and the larger ellipse surmounted by imposts, mortised on tenons in the tops of the uprights, and also by the larger stones being thus at least partially tool-dressed. In Norway and Sweden the few stone circles systematically explored have been found to be burial-places of the iron age. They are usually simple circles composed of eight to thirteen stones; occasionally there are two concentric circles, one within the other, the inner circle being sometimes composed of small stones set close together in a ring. Sometimes there is a single pillar-stone in the centre of the circle. As a rule they are not remarkable either for the size of the circles themselves or for the massiveness of the stones of which they are composed. Circles of standing-stones are rare to the south of the Baltic. In France they are comparatively few in number, and scarcely anything is yet known of their contents. In Algeria megalithic circular burial-places are not uncommon, but they do not correspond in general with those of northern Europe, being rarely composed of pillar-stones. Circles of pillar-stones, apparently of comparatively recent origin, have been found in northern India, and megalithic circles are stated to have been occasionally met with east of the Jordan, and in northern Arabia.

See Ferguson's *Rude Stone Monuments* (Lond. 1872); Anderson's *Scotland in Pagan Times* (Edin. 1886); *Plans and Photographs of Stonehenge*, by Sir Henry James (Southampton, 1867).

Stone-coal. See ANTHRACITE.

Stone-crop. See SEDUM.

Stonefield, an industrial town of Lanarkshire, 2½ miles NW. of Hamilton and 8 SE. of Glasgow. It was the scene of riots in February 1887. Pop. (1871) 395; (1891) 4511.

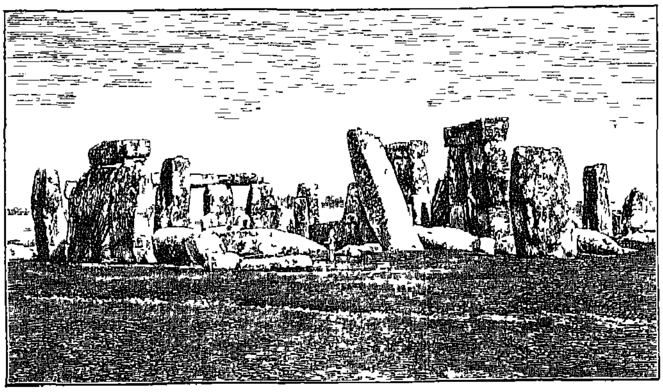
Stone-fly (*Perla*), a genus of insects typical of the order Plecoptera. The hind-wings are broader than the fore-wings, and folded at the inner edge. The body is elongated, narrow, and flattened; the wings fold close to the body, which generally bears two terminal bristles. The larvæ are aquatic, and much resemble the perfect insect, except in the absence of wings. A number of species—e.g. *P. bicaudata*—are common in Britain, and are well known to anglers as an attractive lure for fishes.

Stone-fruit. See FRUIT, Vol. V. p. 20.

Stoneham, a town of Massachusetts, 9 miles N. of Boston, with which it is connected by rail and tram. It has large boot and shoe factories. Pop. (1890) 6140.

Stonehaven (locally *Stanehive*), a seaport and (since 1607) the county town of Kincardineshire, 16 miles SSW. of Aberdeen, is situated on a rocky bay at the mouth of Carron Water, which divides it into an Old and New Town. The harbour, formed since 1826, can admit only small vessels; but Stonehaven has very considerable herring and haddock fisheries. It was constituted a police-burgh in 1889. Pop. (1841) 3012; (1891) 4497. See DUNNOTTAR.

Stonehenge (Saxon *Stanhengist*, 'the hanging stones'), a circular group of gigantic standing stones on Salisbury Plain, about 2 miles from Amesbury in Wiltshire, situated in the midst of an extensive group of prehistoric barrows of the bronze age. The circle of stones, which is about 100 feet in diameter, occupies the central portion of an area of about 360 feet in diameter, enclosed within an earthen rampart and ditch. It consists of two concentric circles enclosing two ellipses, both open at the north-east end. The exterior circle, which is composed of pillar-stones of Tertiary sandstone, locally called 'sarsens,' set up at pretty regular intervals of about 4 feet apart, has been surmounted by a continuous line of imposts closely fitted to each other at the extremities, and having mortise-holes in their under sides, which receive tenons on the tops of the pillar-stones. The pillar-stones show generally about 13 feet of height above the ground, and the imposts are about 10 feet long, 3½ feet wide, and 2 feet 8 inches deep. Of this circle seventeen pillar-stones and six imposts retain their original position. About 9 feet within the exterior circle are the remains of a second circle of smaller undressed blocks or boulders of primitive rock, locally known as 'blue stones.' They are irregular in shape and height, and do not seem to have supported imposts, but few now remain standing, and their number and respective positions cannot be accurately determined. Within this inner circle, and separated from it by about the same distance, is an incomplete ellipse, nearly of horse-shoe form, with the open end facing the north-east, formed of five trilithons or groups of two immense pillar-stones supporting an impost. The central trilithon facing the open end of the ellipse is the largest, the pillar-stones being about 23 feet in height above ground, and the added height of the impost making the whole height of the trilithon nearly 28 feet. The dimensions of this trilithon given by Sir Henry James are: height of uprights out of ground, 22 feet 5 inches; breadth, 7 feet 6 inches; thickness, 4 feet: length of impost, 15 feet; breadth, 4 feet 6 inches; thickness, 3 feet 6 inches. The other four, which stood facing each other, two and two on opposite sides of the ellipse, are somewhat smaller. Only two are now perfect; the central one wants the impost, which fell in 1620, one of the pillars lies broken on the great stone, popularly called 'the altar stone,' and the other leans over, supported by one of the smaller stones in front of it. Of the two trilithons on the west side of the ellipse, the one next the open end has only one pillar-stone standing, the other has fallen inwards with the impost, and both are broken; *the other trilithon fell outwards in 1797*, but the three stones, though prostrate, are still entire. The trilithons of the ellipse are of the same Tertiary sandstone as the pillar-stones and imposts of the exterior circle, and like them are partially tool-dressed. Within this ellipse is a smaller ellipse of the same form, but composed, like the second circle, of irregularly-shaped 'blue stones' without imposts, varying from 6 to 8 feet in height, and set at intervals of about 5 to 6 feet.



Stonehenge.

Though not mentioned by any Roman writer, or noticed by Gildas, Nennius, or Bede, Stonehenge comes into the cycle of British history in the 12th century, when it is chronicled by Henry of Huntingdon as one of the four wonders of England, the other three being merely natural phenomena. In the same century Geoffrey of Monmouth, in his *Historia Britonum*, attributes its erection to Aurelius Ambrosius, in commemoration of the British nobles treacherously slain by Hengist, and mentions that Aurelius himself was buried in it. Again, in recording the death of Constantine about the middle of the 6th century, he states that he was buried 'close by Uther Pendragon, within the structure of stones which was set up with wonderful art not far from Salisbury, and called in the English tongue Stonehenge.' Though Geoffrey's narrative is in the main mythical, it may be accepted as the earliest record of what was believed to be the purpose of Stonehenge. His story is repeated with little variation by all the mediæval writers to the time of Camden. He copied a drawing of it, signed 'R F 1575,' which (making every allowance for bad drawing) shows its outer circle much more complete than at present. Inigo Jones, in 1620, laments the disappearance of stones that were standing when he measured it. Stukely deplores the loss of the fallen stones carried away to make bridges, mill-dams, and the like. Aubrey mentions a large stone carried away within his remembrance to make a bridge. Though the area within the circle has never been systematically explored, flint flakes, fragments of rude pottery similar to the urns found in the neighbouring barrows, bones of oxen, and portions of stags' horns, have been found at various times in desultory excavations made in the hope of discovering some clue to the unknown purpose or uses of the structure. The theories propounded in modern times on these points have been many and various. It has been attributed to the Phœnicians, the Belgæ, the Druids, the Saxons, and the Danes. It has been called a temple of the sun, and of serpent-worship, a shrine of Buddha, a planetarium, a gigantic gallows on which defeated British leaders were solemnly hung in honour of Woden, a Gilgal where the national army met and leaders were buried, and a calendar in stone for measurement of the solar year. The opinion of Sir John Lubbock, expressed in his *Prehistoric Times*, is that there are satisfactory reasons for assigning it to the bronze age, though apparently it was not all erected at one time, the inner circle of small unwrought 'blue stones' being probably older than the rest. By most archæologists it seems to be accepted as an exceptional development from the ordinary type of Stone Circles (q.v.), used as burial-places by the bronze-age people of Britain, though some regard its exceptional development as due rather to a religious influence than to the mere idea of the common commemoration of simple burial. But whatever may have been its origin or purpose, it is sufficiently interesting as the grandest megalithic monument in Britain.

Stonehenge, the pseudonym of John Henry Walsh (1810–88), a native of Hackney, a surgeon at Worcester, and from 1857 editor of *The Field*, author and editor of works on dogs and sport.

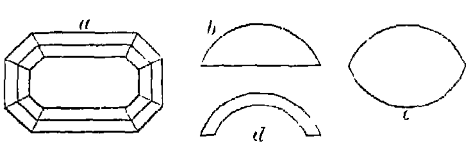
Stone River. See Murfreesborough.

Stones, Precious. In this category are included numerous mineral substances, and one or two products of organic origin, used in jewellery and for other ornamental purposes on account of their rarity and beauty. The list of stones which may be regarded as precious cannot be definitely limited, as certain substances appear and disappear with the fluctuations of fashion. Some confusion also arises from the commercial application of the same name to several substances which may have a superficial similarity, although they really belong to distinct mineral species. Further, in point of beauty and rarity, the mineral substances used for ornament so merge into the common and abundant that there is no possible dividing line between precious and common stones. Among the substances used ornamentally, however, there are a few which from all times have occupied a foremost place and have been universally prized as precious stones. In such a rank and position may be placed the diamond, the ruby, the sapphire, the oriental amethyst, and the emerald. These, on account of their rare properties—their lustre, their play of light, their brilliance of colour, their great hardness and consequent durability, and especially because of their extreme rarity, have always been the most esteemed of jewel stones. In the second rank, as well-established precious stones of minor value, may be included the spinel or balas ruby, the Brazilian topaz (the oriental topaz is a yellow sapphire), the varieties of garnet, the turquoise, the tourmaline, the aquamarine or pale emerald, the chrysoberyl or cat's eye, the zircon or jargon, the opal, and the varieties of quartz, such as rock-crystal, agate, amethyst, cairngorm or Scotch topaz, chalcedony, jasper, onyx, sardonyx, &c. Among other beautiful and valuable stones much appreciated for ornamental purposes, but scarcely to be classed as precious stones, there may be included lapis lazuli, crocidolite, labradorite, moonstone, avanturine, and malachite. To the list of precious stones there should be added two substances of animal origin—pearls and red coral—and perhaps also amber, a comparatively rare and valuable fossil resin. The various substances here enumerated are dealt with, for the most part, under their own proper names.

For the development of the sparkle, lustre, and glow of colour of most precious stones it is essential that they should undergo the process of cutting and polishing. When lustre and sparkle are the principal qualities to be revealed, as in the case of the diamond, the surface is most favourably cut into numerous plane facets as either brilliant or rose cut stones (see DIAMOND, figs. 1 and 3). When colour is the more important quality of the stone it may, if plane surfaces are wanted, be step or table cut (*a* in fig.). Such stones also, and translucent and opaque stones, may be cut *en cabochon*—i.e. with curved or rounded surfaces.



The varieties of cabochon cutting are single cabochon (*b*), or high plano-convex double cabochon (*c*), and double convex and hollow cabochon (*d*), the latter being much used for large garnets, which so cut are called carbuncles.

One of the most important qualities of a precious stone is its hardness, as upon that property depends its power of resisting wear and of keeping the brilliance of its polished surface. It is a property of great constancy, moreover, and in many cases affords a ready means of determining the nature of a stone under examination. Of all known substances diamond is the hardest, and representing it, according to Mohs's scale, by 10, the following is the relative hardness of several of the more important of the precious stones: Diamond, 10·0; sapphire, 9·0; ruby, 8·8; chrysoberyl, 8·5; spinel, 8·0; topaz, 8·0; aquamarine, 8·0; emerald, 7·8; zircon, 7·8; tourmaline, 7·5; amethyst, 7·0; moonstone, 6·3; turquoise, 6·0; opal, 6·0.

Artificial Precious Stones.—Numerous attempts have been made by eminent investigators to produce artificial precious stones by means of intense heat and pressure and by electrical action; but hitherto these efforts have failed of practical success. In an important memoir published by Sainte Claire Deville and Caron in 1858 (*Comptes Rendus*, vol. xlvi.) they describe various processes by which they obtained small crystals of corundum, ruby, sapphire, &c. By the action of the vapours of fluoride of aluminium and boracic acid on one another, they obtained crystals which, in hardness and in optical properties, resembled natural corundum. When a little fluoride of chromium was added a similar process yielded violet-red rubies; with rather more fluoride of chromium blue sapphires were yielded; and with still more green corundum was obtained. A mixture of equal equivalents of the fluorides of aluminium and glucinum, when similarly acted on by boracic acid, yielded minute crystals of chrysoberyl. The action of fluoride of silicon on zirconia yields small crystals of zircon, and by the action of silica on a mixture of the fluorides of aluminium and glucinum hexagonal plates of extreme hardness were obtained, which in some respects resembled emerald.

In subsequent researches Becquerel (*Comptes Rendus*, vol. lviii.), by the use of electric currents of high tension, succeeded in obtaining opals, &c. from solutions of silicates. Among the most successful of experimenters in this direction was the late Ch. Feil of Paris, who successfully crystallised alumina, and by the introduction of colouring matter produced sapphires and rubies identical in hardness and composition, but not in brilliance, with the natural stones. M. Feil also succeeded in preparing true crystals of spinel, and a blue lime spinel of great hardness, but which were glassy rather than crystalline in structure.

Imitations of precious stones consist of a soft, heavy flint-glass called Strass (q.v.) or paste, appropriately coloured, and they may readily be distinguished, among other peculiarities, by their great softness. Fraudulent combinations are made by cementing thin plates of precious materials over, and sometimes also under, a body of valueless glass, and thus the exposed surface or surfaces when tested are real stones, and the veneered mass passes as a genuine large and consequently valuable possession.

See works by H. Emanuel (1865), W. Jones (1879), A. Delmar (1880), Professor A. H. Church (1883), E. W. Streeter (new ed 1884), M. D. Rothschild (New York, 1889), and G. F. Kunz (New York, 1890).

Stone-worship. See FETICHISM, IDOLATRY.

Stonington, a town and port of Connecticut, on the Atlantic, 14 miles by rail E. of New London, and at the junction of one of the railway and steamer routes between New York and Boston. It has a capacious harbour, a foundry, and tin-factories. Pop. (1890) 7184.

Stonyhurst, a great Roman Catholic college in north-east Lancashire, 4 miles SW. of Clitheroe, traces its origin to the seminary at St Omer (q.v.) in France, which was founded in 1592 by Father Parsons (q.v.). The seminary ere long had 200 students, but after many vicissitudes was suppressed by the tyranny of the Bourbons in 1762. After a short sojourn at Bruges till 1772, and at Liége till 1794 (when the French revolutionary armies were closing round it), the eighteen Jesuit fathers were offered a resting-place at Stonyhurst by Mr Weld of Lulworth, an old alumnus, to whose family the old home of the Shireburnes had in 1754 passed by marriage. The fine house, begun about 1594, was beginning to fall into ruin, and even when restored provided but scant accommodation for the 200 students who soon flocked to it. Extensions were made in 1810–78, the chapel being built in 1835, and other additions have been lately completed. The numbers have gone on increasing with some fluctuations, and are now about 300. The teaching staff numbers over thirty masters; and there is a preparatory school at Hodder, a mile distant. The department for higher education prepares young men for the London University degree and competitive examinations, and puts them through a course of philosophy. In 1840 Stonyhurst was affiliated to the University of London, and it has a long list of successes in the various examinations, especially classics. Between 1840 and 1890 about 400 passed the matriculation examination, of whom ninety took honours. The B.A. degree was taken by 120, half of these securing places on the classical honours list, and ten took M.A. in classics and mathematics. The course is mainly classical, but mathematics receives a large share of attention; and French, science, and other branches are essential parts of the course. Games are much encouraged, and special forms of football and handball seem to have been brought from St Omer.

The college eleven is well known. There is a covered playground, swimming bath, gymnasium, and workshop; and the debating club and college magazine are prosperous institutions. The library of some 40,000 volumes has many valuable MSS. and early printed books; and the college possesses a collection of pictures, a museum of antiquities, scientific collections, and fine specimens of embroidery and church-plate in the sacristy (many of these treasures having been preserved from St Omer days). The college observatory rose into some note under Father Perry, F.R.S. Many of the institutions of this college—the names of classes, exercises, holidays—date from the residence abroad.

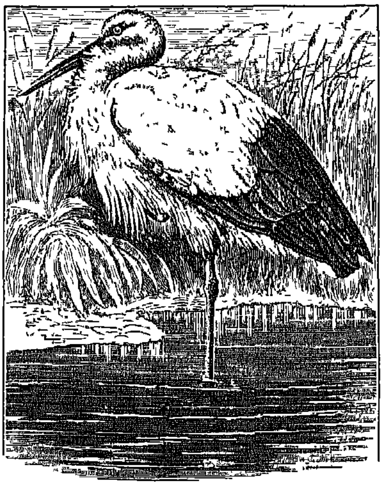
See Hewitson, *Stonyhurst College, its Past and Present* (Preston, 1870; 2d ed. 1878); *Memorials of Stonyhurst College* (1881); A. Rimmer, *Stonyhurst Illustrated* (1884), and *Stonyhurst Lists, 1794–1886*, by John B. Halt (1886).

Stony Stratford, a market-town of Bucks, on Watling Street and the Ouse, 8 miles NE. of Buckingham. It had an Eleanor cross till 1646, and suffered much from fire in 1742. Pop. 1943.

Stool of Repentance, one of several names for an engine of ecclesiastical discipline in Scotland, also known as the 'pillory' or 'pillar,' the 'high place,' the 'public spectacle,' and in familiar reference the 'cutty-stool'—a term ordinarily in use for a domestic wooden stool with short legs. The place of repentance was sometimes a stool or bench, sometimes a pew or part of the gallery, sometimes a special erection as high as the gallery, containing several seats or stances, and ascended by stairs. Whatever it was and whatever called, it was about the most conspicuous thing in the church; and here persons who had become subject to ecclesiastical discipline for immoral conduct were required by the kirk-session to stand during public worship in profession of their penitence. The penitent was usually bare-headed and bare-footed, clothed in sackcloth or a linen sheet (kept for the purpose by the kirk-session); the ceremony might or might not be concluded by a public rebuke from the minister. For minor offences one appearance in the place of penitence might suffice; for the sin of fornication three several Sundays' penitence were usually inflicted; a much larger number of days was not at all unusual; and some offences (such as incest) might imply fifty-two Sabbaths in the place of penance unless the culprit were condemned by the civil courts to capital punishment. The stool of repentance was steadily maintained during great part of the 18th century, but gradually fell into desuetude, its place being taken by public rebuke before the congregation (still enforced in some places to near the middle of the 19th century), and afterwards by rebuke administered in presence of the session only. See Dr Edgar on 'Discipline' in *The Church of Scotland*, vol. v. (1891).

Storax, a resin resembling benzoin, was in high esteem from the time of Pliny to the end of the 18th century. It was obtained from the stem of *Styrax officinalis*, a native of Greece and the Levant, but owing to the destruction of the trees it has now disappeared from commerce. It was used as a stimulating expectorant.—LIQUID STORAX, a soft viscid resin, opaque and gray brown, heavier than water, is obtained from the *Liquidambar orientale*, a tree 40 feet high, forming forests in the south-west of Asia Minor. It has a balsamic odour and a pungent burning aromatic taste. It contains from 6 to 20 per cent. of cinnamic acid, besides a hydrocarbon, *Styrol*, a volatile oil, and various fragrant ethers. It is used but seldom in medicine, but has a reputation in chronic bronchial affections. Externally it has been employed in scabies.

Stork, a group of birds characterised by having the bill larger than the head, very stout at base, not grooved, tapering to the straight recurved or decurved tip; nostrils pierced directly in the horny substance, without nasal scale or membrane, high up in the bill, close to its base; legs long, and with reticulate scaling; three toes, with sometimes a rudimentary fourth, the claws not acute. The storks are usually divided into the True Storks and the American 'Wood Ibises' (*Tantalus*). There are several genera of storks, including about a dozen species. They belong chiefly to the Old World. The most familiar representative of the family is the Common Stork or White Stork (*Ciconia alba*), a native of the greater part of the Old World, a migratory bird, its range extending even to the northern parts of Scandinavia. It is common in many parts of continental Europe (though not in France, Italy, or Russia), but is especially familiar in Holland and North Germany, the storks arriving annually in February and March, and in autumn returning to Africa in large flocks, flying mostly by night. It is about three feet and a half in length. The head, neck, and whole body are pure white; the wings partly black; the bill and legs red. The neck is long, and generally carried in an arched form; the feathers of the breast are long and pendulous, and the bird often has its bill half hidden among them. The flight is very powerful and high in the air; the gait slow and measured. In flight the head is thrown back and the legs extended. The stork sleeps standing on one leg, with the neck folded, and the head turned backward on the shoulder. It frequents marshy places, feeding on eels and other fishes, frogs, lizards, snakes, slugs, young birds, small mammals, and insects. It makes a rude nest of sticks, reeds, &c. on the tops of tall trees, or of ruins, spires, or houses. There are four or five eggs, white tinged with buff; and the old nest is re-occupied next year. In many parts of Europe, especially in Holland, it is a very common practice to place boxes for storks, and it is considered a fortunate thing for a household that the box on the roof is occupied: children are told it is the storks that bring the babies out of the well. Storks are protected by law in some countries, on account of their good services not only in destroying reptiles and other troublesome animals, but



Common Stork (*Ciconia alba*).

in the removal of offal from the streets of towns, in which they stalk about with perfect confidence, even in the midst of throngs of people. They have been celebrated from ancient times for the affection which they display towards their young, and have also had the reputation—not so well founded—of showing great regard to their aged parents. Before they take their departure from their summer haunts they congregate in large flocks, which make a great noise by the clattering of their mandibles, and are popularly regarded as holding consultation. The stork has no voice. It is a very rare bird in Britain, and was so even when the fens of England were undrained. Bower says that in 1416 storks came and built their nests on the roof of St Giles' Church in Edinburgh; there they remained a year and departed to return no more; 'and whither they flew,' adds the chronicler, 'no man knoweth.' The flesh of the stork is rank and not fit for food. The Umbrette (*Scopus umbretta*), an African and Madagascar bird, remarkable for the enormous domed nest which it builds, is nearly allied to the storks and seems to be a link connecting them with the herons. The Balæniceps (*q.v.*) or Shoe-bill is also a stork.

Storm, THEODOR WOLDSEN, German poet and writer of short stories; a native of Sleswick, he was born at Husum on 14th September 1817. He spent most of his life (1842–80) as magistrate and judge in the service of Sleswick-Holstein and Prussia, and died at Hademarschen in Holstein on 3d July 1888. His poetic reputation rests upon his *Gedichte* (1852; 8th ed. 1890). Of his stories, mostly short, the best are *Immensee* (1852; 33d ed. 1890), a poetic idyll in prose; *Zerstreute Kapitel* (1873); *Aquis Submersus* (1877); *Psyche* (1877); *Carsten Curator* (1878); *Hans und Heinz Kirsch* (1883); *John Riew* (1886); and *Der Schimmelreiter* (1888). The charm of these little tales lies in the poetic and idyllic atmosphere in which the action is placed, the unobtrusive skill with which they are told, and their deep feeling. See Lives of Storm by Schutze (1887) and Wehl (1888).

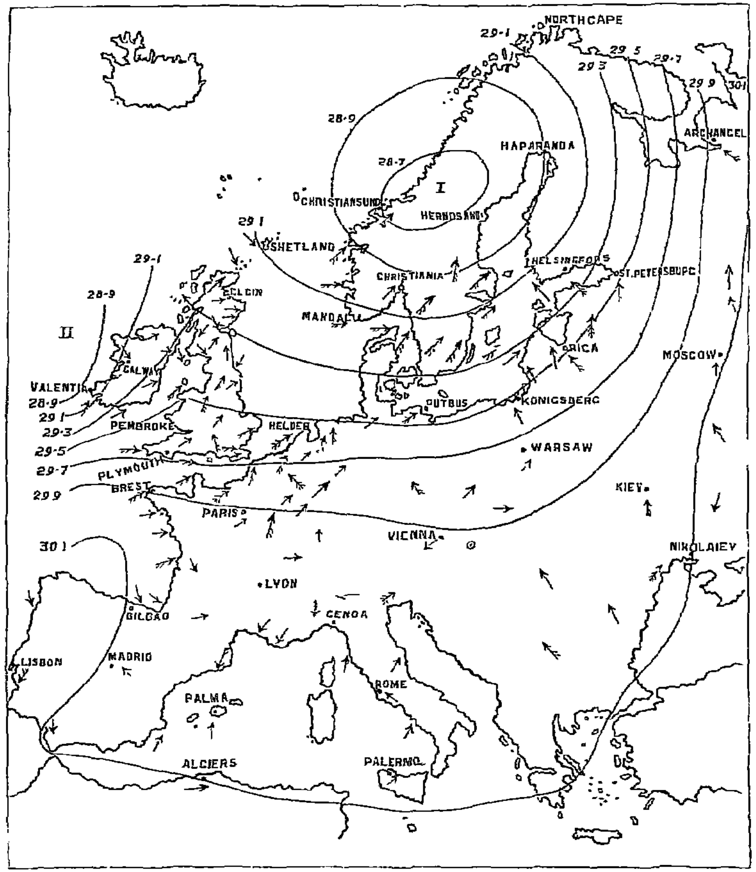
Stormontfield. See PISCICULTURE.

Storms are violent commotions of the atmosphere occurring in all climates, particularly in the tropics, and differing from other atmospheric disturbances in the extent over which they spread and the sudden changes which take place in the direction of the wind over wide areas. There is, perhaps, no question in science in which there was long so large an admixture of speculation with fact as in the attempts made to reduce the phenomena of storms under general laws; the reason being that meteorological observatories were too few in number and too wide apart to represent the barometer pressure, the general course of the winds, and the rainfall, without drawing largely on conjecture. Since about 1860, however, sufficient data have been available for a fuller and more satisfactory statement of the facts.

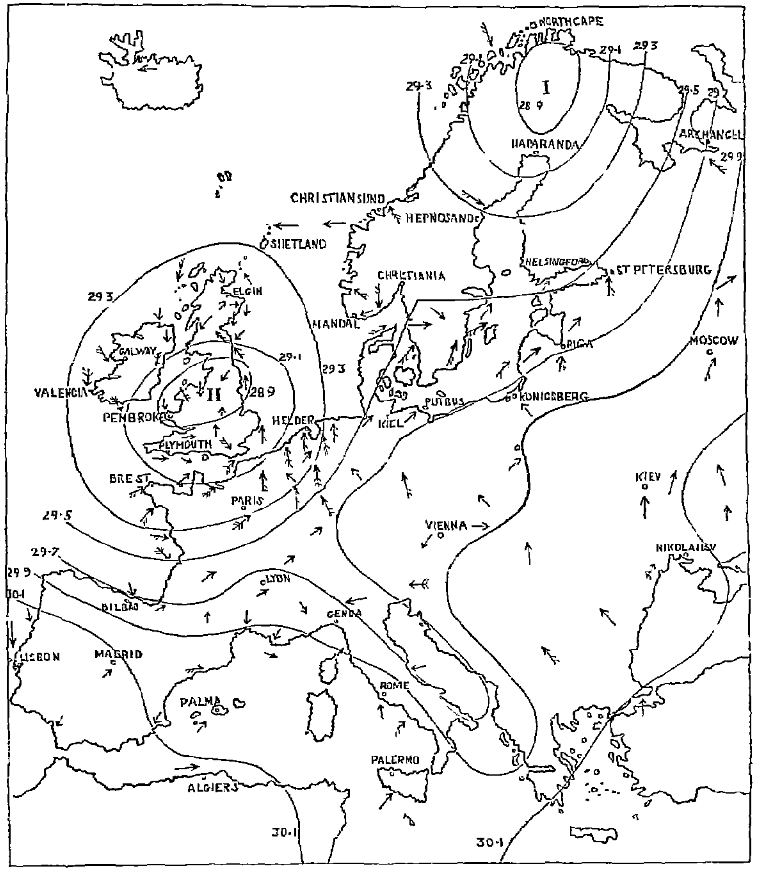
Form and Extent of Storm Areas.—The circular isobaric lines on the charts represent very fairly the form storms usually assume in Europe, where the area of almost every storm is either circular or elliptical, the major axis of the ellipse being generally less than twice the minor axis. Rarely in Europe, but in America less rarely, is the form of storms much more elongated. The outline is occasionally very irregular, but in such cases the storm will be found to have parted into two or more distinct storms, or it comprises within the low-pressure area several satellite storms. The approximate circular form of storms is their general characteristic. This is a most important feature, whether as determining the practical rules for the guidance of sailors in storms, or for the forecasting of storms at particular seaports, in respect of the direction from which they may be expected to come, and the veerings of the winds during their continuance. The extent over which storms spread is very variable, being seldom less than 600 miles in diameter, but often two or three times greater, and more rarely even five times that amount. More than the whole of Europe is sometimes overspread by a single storm at one time. The prime difference between storms or *cyclones* and *tornados* is that the breadth of the space traversed by the latter is, as compared with that of storms, always quite insignificant. The area of storms is not constant from day to day, but varies in size, sometimes expanding and sometimes contracting; and it is worthy of remark that when a storm contracts in area the central depression gives signs of filling up, and the storm of dying out. On the other hand, when it increases in extent the central depression becomes deeper, the storm increases in violence, and occasionally is broken up into two or even more depressions, which become separate storms, with the wind circling round each. This occurs frequently with summer thunderstorms.

We subjoin two charts of Europe showing from observations made at upwards of 100 stations scattered over the continent the barometric pressure, and direction and force of the wind, at 8 A.M. of the 1st (A) and 2d (B) of November 1863, during part of the course of two storms which passed over Europe. The isobaric lines, or lines showing where, at the above hour, the barometer was the same, are given for every two-tenths of an inch in the difference of the pressure. Hence, where these lines crowd together, the difference of pressure, or the atmospheric disturbance, was the greatest, and the least where they are most apart—a distinction of the utmost importance in determining where the wind raged in greatest fury. The arrows show the direction of the wind, being represented flying with it. The force of the wind is shown (1) by plain arrows, ⟶, which represent light and moderate winds; (2) by arrows feathered on one side only, ⫽⟶, which represent high winds; (3) by arrows feathered on both sides, ⋙⟶, which represent strong gales, storms, or hurricanes.

Direction in which Storms advance.—The direction in which their progressive motion takes place differs in different parts of the world—being perhaps determined by the prevailing winds (see WINDS). Thus, about half the storms of middle and northern Europe travel from the south-west toward the north-east, and about nineteen out of every twenty travel toward some point in the quadrant lying between the north-east and the south-east. Storms rarely travel towards a westerly point; in some of the instances which have been noted the western course has been arrested at Norway, Denmark, the North Sea, or the British Islands, but such westerly course is temporary, the easterly course being afterwards resumed. Some of the most violent easterly storms fall under this head. Storms do not always proceed in the same uniform direction from day to day, and, though the change which occurs in the direction of their progressive motion is generally small, yet occasionally it is very great. Thus, of the many interesting features peculiar to the storm which passed over Europe in the beginning of December 1863 none were more remarkable than the sudden changes of its progressive motion. It was first observed on the west of Ireland, from which it advanced east to Liverpool, then turned south through Worcester and Oxford to Cherbourg in France; it thence retreated north through Oxford to Shields, from which it



Storm Chart A.



Storm Chart B.

proceeded east to Copenhagen. By the time it arrived at Copenhagen its extent was only a fourth of what it had been the previous day, and the central depression half an inch less. Twelve hours later the atmospheric equilibrium was restored, the storm having died out on reaching the Baltic Sea. The storms of the Mediterranean follow a different course. While a number take the general easterly course of European storms, a larger number originate in the gulfs of Lyons and Genoa, and pursue devious courses over this northern extension of the Mediterranean, till they die out; several advance from Turkey and Greece towards the Alps; and others, comparatively few, advance in an easterly course towards the Levant. A marked feature of these Mediterranean storms, including those of the Adriatic, is their slow, frequently retrograde, and erratic courses, and the small space traversed by them; and while they last the mistral, with dry cutting wind, sweeps down from the Alps on the health-resorts of southern France. By far the greater number of the storms of North America take their rise in the vast plain which lies to the east of the Rocky Mountains, and thence advance in an eastern direction over the United States, their course being largely determined by the great lakes; some of them cross the Atlantic, and burst on the western shores of Europe. But the connection of the American with the European storms is not even yet well established. The storms of the West Indies generally take their rise somewhere north of the region of calms, and, tracing out a parabolic course, proceed first towards the west-north-west, and then turn to the north east about 30° N. lat., not a few traversing the east coasts of North America as far as Nova Scotia. South of the equator they follow an opposite course. Thus, in the Indian Ocean they first proceed toward the south-west, and then gradually curve round to the south-east. The *hurricanes* of India usually pursue a parabolic path, first traversing the eastern coast towards Calcutta, and then turning to the north-west up the valley of the Ganges. The *typhoons* of the Chinese Seas resemble, in the course they take, the hurricanes of the West Indies.

Probably the course tracked out by storms is determined by the general system of winds which prevail, modified by the unequal distribution of land and water on the surface of the globe, the diffusion of the aqueous vapour, and its concentration over the regions traversed by the storms. Facts seem at present to point to the general conclusion that storms follow the course of the atmospheric current in which the condensation of the vapour into the rain which accompanies them takes place.

Rate at which Storms travel.—If the position of the centre of storm I. in chart B be compared with its position on the 1st on the charts, it will be found to have travelled 420 miles in 24 hours, or at the rate of 17½ miles an hour. Similarly storm II. will be found to have travelled in the same time 400 miles, or at the rate of 16⅔ miles an hour. This is not far from the average rate of the progressive movement of European storms. From an examination of extensive series of storms Professor Loomis has shown that the average rates of progress of storm centres are in miles per hour 28 for the United States, 18 for the middle latitudes of the Atlantic Ocean, 17 for Europe, 15 for the West Indies, and 9 for the Bay of Bengal and China Sea. On January 7-8th 1877 a storm travelled in 24 hours from Indianola (Texas) to Eastport (Maine)—1872 miles, or 78 miles an hour. On the other hand, the rate of progress is, particularly in the tropics, sometimes so slow as to be virtually stationary; and, as already stated, they occasionally recurve on their paths.

Relations of Temperature, Rain, and Cloud to Storms.—Temperature increases at places toward which and over which the front part of the storm is advancing, and falls at those places over which the front part of the storm has already passed. In other words, the temperature rises as the barometer falls, and falls as the barometer rises. When the barometer has been falling for some time clouds begin to overspread the sky, and rain to fall at intervals; as the central depression approaches the rain becomes more general, heavy, and continuous. After the centre of the storm approaches, or shortly before the barometer begins to rise, the rain becomes less heavy, falling more in showers than continuously; the clouds break up when the centre has passed, and fine weather, ushered in with cold breezes, ultimately prevails. If the temperature begins to rise soon and markedly after the storm has passed, a second storm may be shortly expected.

Direction of the Wind.—If the winds in storm II. in chart B be examined, they will be observed whirling round the area of low barometer in a circular manner, and in a direction contrary to the motion of the hands of a watch, with a constant tendency to turn inwards towards the centre of lowest pressure (i.e. in the manner formulated in Buys-Ballot's law). The wind in storms neither blows round the centre of lowest pressure in circles, nor does it blow directly towards that centre, but takes a direction nearly intermediate, approaching, however, nearer to the direction and course of the circular curves than of the radii to the centre. In the front of the storm the winds blow more towards the centre, but in the rear they blow more closely approximate to the circular isobaric lines. Where the direction of the wind differs to any material degree from the above it is light, and consequently more under local influences, which turn it from its true course. Thus, the centre of the storm being near Liverpool, the direction of the wind is south-west at Paris, south at Yarmouth, north-east at Silloth, north at Dublin, and north-west at Cork—instead of south at Paris, south-east at Yarmouth, north at Silloth, north-west at Dublin, and west at Cork, if it had blown directly to the area of lowest pressure, and west at Paris, south-west at Yarmouth, east at Silloth, north-east at Dublin, and north at Cork, if it had circulated in the direction of the isobaric curves. Hence in this storm the winds circulate round the centre of least pressure, or, to speak more accurately, the whole atmospheric system flows in upon the centre in a vorticose manner. This peculiarity is common to all storms in the northern hemisphere that have yet been examined. In the southern hemisphere a rotatory motion is also observed round the centre of storms, but it takes place in a contrary direction, or in the direction of the motion of the hands of a watch, instead of contrary to that direction, as obtains north of the equator.

Professor Taylor first applied Dove's law of rotation to explain the direction of the rotation of storms round their centre. This may be explained by referring to storm II. in chart B. On that morning the pressure over England being much less than in surrounding countries, if the earth had been at rest air-currents would have flowed from all directions to England, to fill up the deficiency, in straight lines. The earth, however, is not at rest, but revolves from west to east; and, as the velocity of rotation diminishes as the latitude increases, it is evident that the current, which set out say from Lyons to the north, would, on account of its greater initial velocity when it arrived at Paris, blow no longer directly to the north, but to a point a little to the east of north; in other words it would no longer be a south, but a south-west wind. Again, since the current from the north of Scotland had a less velocity than those parts of the earth's surface on which it advanced, it lagged behind, and consequently by the time it arrived at Silloth in the north of England had changed from a north to a north-east wind. Similarly the north-west current changed to a north, the south-west to a west, &c. The west and east currents, since they continued in the same latitude, would have blown in the same direction, if they had not been disturbed by contiguous currents. Hence in a storm the whole system of winds appears *to rotate round the centre*. As a further confirmation of this theory, it is observed that when a high pressure covers a limited space the wind is always observed gently *whirling out of this area of high barometer*, but in exactly opposite directions in both hemispheres from those assumed when it blows round and in upon an area of low pressure. It follows in the northern hemisphere that as storms advance the general veering of the wind at places lying north of the path of their centre is from north-east by north to west, and at places south of their centre from north-east by east and south to north-west, and conversely in the southern hemisphere.

Force of the Wind.—The rule is simple, and without exception—viz. the wind blows from a high to a low barometer with a force proportioned to the barometric gradient or to the difference of the barometric pressures reduced to sea-level. Hence where the isobaric lines crowd together the violence of the storm is most felt, and where they are far asunder the winds are moderate, light, or *nil*. We thus see the importance of observations from a distance in forecasting the weather. To take an illustration: the importance of observations from Norway and Sweden to all seaports on the east coast of Britain cannot be overestimated, for if the pressure be high in Norway and low in the North Sea or in the south of Great Britain violent easterly gales will sweep down on Scotland, and, unless foreseen and provided against, strew the coast with wrecks; whereas if the pressures be nearly equal little danger need be apprehended, even though the barometer be low in Britain. As the wind nears the centre of the storm it gradually abates, till on reaching the centre a lull or calm takes place—a peculiarity more uniformly noted as regards tropical storms. Calms and light winds also prevail along the ridge of highest barometer, or the region where the pressure is greatest, and on receding from which the pressure diminishes on each side. This arrangement of the pressure is accompanied with fine weather and the 'pet' days of winter. It may not inaptly be compared to the watershed in physical geography, since from it the wind flows away on either hand towards the places where pressure is less.

The *progressive motion* of storms, which may vary from zero to 78 miles an hour, measures the time taken in passing from one place to another, but it gives no indication of the violence of the storm. This is determined by the velocity of the wind round and inwards upon the centre of the storm, which in Europe and America frequently amounts to 60 or 80 miles an hour continuously for some time. In intermittent gusts a speed of 120 miles an hour has been several times observed in Britain—a velocity which is perhaps sometimes surpassed by storms within the tropics. On the top of Ben Nevis higher velocities, rising to upwards of 150 miles, are of not infrequent occurrence.

Cause of Cyclones.—Dove, who did so much in this department of meteorology, held the view that cyclones are formed when two great atmospheric currents, called polar and equatorial, flow side by side, storms being the eddies, as it were, formed along the line of junction. It is to be kept in mind that the qualities of the atmosphere in the front portion of a cyclone are quite different from those in the rear—the former being warm and moist, while the latter are cold and dry. The conclusion is inevitable that the apparent rotation of winds in storms is simply a circulatory movement maintained between two currents, and that no mass of the same air makes the complete circuit of the cyclone. This feature of storms will, if rightly apprehended, play an important rôle in the *development of the theory of the law of storms* which lies yet in the future. The height to which storms extend in the atmosphere, as has been shown from the Ben Nevis observations, is greatly less than had been supposed.

Forecasting.—Valuable aid in forecasting storms and weather is derived from two important deductions from past observations: I. A cyclone tends towards a path near to the anticyclone which lies immediately to the right of the progressive motion of the storm at the time. II. When the rates of fall of the barometer at stations in the west of Europe are noted, it is found that the path taken by the coming storm is indicated by those stations at which the rates of fall of the barometer are greatest.

Relation of Storms to the Character of the Season.—This is vital and all-important. Thus, as regards the British Islands, when the general path pursued by storms in their easterly course over Europe lies to the southward the winter is severe, inasmuch as the British Islands are then on the north side of the centre of low pressure, and consequently in the stream of the northerly and easterly winds which there prevail. On the other hand, when the paths of storms lie to the northward the British Islands are on the south side of the low pressure, and therefore in the stream of the warm, moist, southerly and south-westerly winds which there prevail. The weather of December 1890 and that of February 1891 illustrate these two distinct types of weather. In December 1890 the weather was colder in the southern counties of England than it had been during the present century. At Oxford the temperature was 10·0° under the average, and in the south-western provinces of Russia the mean temperature was fully 14·0° below the average. On the other hand, to the north of a line drawn from Wilna to Bergen temperature was above the average, the excess above the mean increasing on advancing northward till in the north of Norway it was 10·0°, and at the entrance of the White Sea 13·0°. In the same month in the Eastern States and Canada temperature was under the average, the deficiency being 11·5° at Montreal; whereas over the rest of the United States temperature was high, the excess increasing on proceeding northward till, in Assiniboia, it was from 14·0° to 17·0° above the average. The explanation is at once afforded by the distribution of atmospheric pressure at the time. In Europe pressure was unusually high from the north of Scotland to St Petersburg. But, what is of more importance, it diminished steadily southward over the continent and into the north of Africa, and, on the other hand, also diminished steadily over the north of Europe, being 0·350 inch lower at the North Cape than at Bergen. Consequently the whole of the southern half of Europe was swept by northerly and easterly winds, bitterly cold and dry, and temperature fell unprecedentedly low; but in the north southerly and south-westerly winds inevitably prevailed, bearing to the northern climes the warmth of lower latitudes. In America atmospheric pressure was above the average over a broad area extending from New Orleans to Lake

Huron, while on the one hand over the Eastern States and Canada it fell below the average, and on the other also below the average over Assiniboia. From this distribution of pressure it inevitably resulted that Canada and the Eastern States were swept by cold, dry, north-westerly winds of unusual strength and prevalence, while Assiniboia enjoyed southerly breezes from, as the isobarics and winds show, the low latitudes of the Gulf of Mexico.

It is plain that the character of the weather of any particular day or season is wholly determined by the way in which areas of high and of low atmospheric pressure are distributed over the region during that day or season. Further, the weather of the coming season could certainly be predicted for say the British Islands, if only the general path was known which the centres of the Atlantic cyclones will take in their easterly course over Europe; for if the paths of the winter storms be to the north of Great Britain the winter will be an open one, but if to the south a severe winter is the certain result. Towards the solution of this highly practical problem we look to seamen to put us in possession of a fuller and, above all, an earlier knowledge of the fluctuations of the surface temperature of the Atlantic, and to high-level observatories for the data required in obtaining a clearer insight into the history and theory of storms.

See the articles METEOROLOGY, HAILSTORM, ANEMOMETER, WINDS, &c.; Redfield, *On the Law of Storms* (1840); Espy, *The Philosophy of Storms* (1841); Peddington, *Application of the Law of Storms to Navigation* (1844); Sir W. Reid, *Progress of the Development of the Law of Storms* (1849); Dove, *On the Law of Storms* (Eng. trans. 1862); Meldrum, *Law of Storms and Navigation* (1873); Ferrel, *Storms, Tornados, and Waterspouts* (1878); Loomis, *Contributions to Meteorology* (3 parts, 1885–89); H. G. Hazen, *The Tornado* (New York, 1890); and the daily weather charts and relative memoirs published in Great Britain, United States, Canada, Australia, France, Holland, Germany, Austria, Denmark, Sweden, Russia, India, China, Japan, &c.

Stornoway, a seaport and important fishery-station in Lewis, the chief town of the Outer Hebrides, near the head of a spacious sea-loch, 59 miles N. by W. of Portree in Skye and 180 of Oban. The principal feature is Stornoway Castle, completed in 1870 by Sir James Matheson (1796–1878), at a cost, with the grounds, of £89,000. Pop. (1841) 1354; (1891) 3287.

Storthing (from *stor*, 'great,' and *thing*, 'court'), the legislative assembly of Norway. See Vol. VII. p. 532; also THING.

Story, JOSEPH, an American jurist, was born at Marblehead, Massachusetts, September 18, 1779, graduated at Harvard in 1798, and was admitted to the bar in 1801. He was elected to the state legislature in 1805, and there became a leader of the Republican (Democratic) party. In 1808 he was returned to congress, and in 1811 he was appointed by Madison associate justice of the Supreme Court of the United States, a place he filled with great credit for thirty-four years. In 1829 he became law professor at Harvard, and quickly raised the school to fame and prosperity. Of his many works the most valuable are his *Commentaries on the Constitution of the United States* (1833), on *The Conflict of Laws* (1834), and on *Equity Jurisprudence* (1835–36), which have passed through many editions. His legal writings and decisions are among those oftenest quoted in the higher courts of law. He died September 10, 1845. See the Life by his son (1851), who also prepared an enlarged edition of his *Miscellaneous Writings* (1851).—The son, WILLIAM WETMORE STORY, was born at Salem 12th February 1819, graduated at Harvard in 1838, studied law under his father, and was admitted to the bar. He even entered with spirit on his profession; but soon (1848) the bias towards poetry and art, which had been checked in the father after one luckless venture, drew him to Italy and made him a sculptor. His productions in this field are numerous and of high excellence; and his writings include *Poems* (1847–56–86), *Roba di Roma* (1862), the *Tragedy of Nero* (1875), *Castle St Angelo* (1877), *He and She* (1883), *Fiammetta* (1885), and *Excursions in Art and Letters* (1891). Mr Story has received honorary doctorates from both Oxford and Bologna, and has been decorated by the French and Italian governments.

Stothard, THOMAS, designer and painter, was the son of a London innkeeper, who kept the *Black Horse* in Long Acre, and was born there, 17th August 1755. He received a respectable education in different boarding-schools, and on his father's death, having shown a predilection for the use of the pencil, was bound apprentice to a pattern-drawer in the city, but was released from his engagement before the term of expiry, and betook himself to more artistic work. His first notable effort was a series of designs for the *Town and Country Magazine*, which was followed by his imaginative compositions for Bell's *British Poets* and the *Novelist's Magazine*. The popularity of these was so great that for many years his services were constantly in request by the leading publishers in London. His earliest pictures exhibited at the Royal Academy were 'The Holy Family' and 'Ajax defending the Body of Patroclus.' In 1791 he was chosen an associate, in 1794 a member, and in 1813 librarian of the Academy. He died 27th April 1834. Stothard was a most graceful and facile illustrator. Not less than 3000 of his designs have been engraved, including those to Boydell's *Shakespeare*, *The Pilgrim's Progress*, *Robinson Crusoe*, and Rogers' *Italy* and *Poems*. His paintings, although skilfully 'composed' and finely coloured, are destitute of the originality and force that come from a study of nature. Perhaps the best known is his 'Canterbury Pilgrims,' engraved in 1817. See the Life (1851) by Mrs Bray (q.v.), the widow of his son, CHARLES ALFRED STOTHARD (1786–1821), who acquired a great reputation as an antiquarian draftsman.

Stoughton, JOHN, a learned English divine, was born in Norwich, 18th November 1807, and educated at Highbury College, Islington, and University College, London. Appointed Congregationalist minister at Windsor in 1832, he removed to Kensington in 1843, and here laboured till his retirement in 1875, when the congregation presented him with £3000. From 1872 till 1884 he acted as professor of Historical Theology and Homiletics in New College, St John's Wood. He was Congregational lecturer in 1855, chairman of the Congregational Union in 1856, received the D.D. degree from Edinburgh in 1869, took part in the Evangelical Alliance Conferences at New York (1873) and Basel (1879), and lectured on Missions in Westminster Abbey in 1877.

He edited for many years *The Evangelical Magazine*, and has written many books marked by profound learning, the most important *Church and State Two Hundred Years Ago* (1862); *Ecclesiastical History of England* (5 vols. 1867–74), supplemented by two volumes on the Reign of Anne and the Georges (1878), and two on the period of 1800–50 (1884); *Homes and Haunts of Luther* (1875); *Footsteps of the Italian Reformers* (1881); *Spanish Reformers* (1883); and biographical studies of Wilberforce, William Penn, Howard the philanthropist.

Stour, a river 47 miles long, flowing eastward along the Suffolk and Essex boundary to the sea at Harwich.

Stourbridge, a market-town of Worcestershire, on the Stour, at the border of Staffordshire and the Black Country, 4½ miles S. by W. of Dudley and 12 W. by S. of Birmingham. The famous Fireclay (q.v.) is said to have been discovered about 1555 by wandering glassmakers from Lorraine; and Stourbridge now has glass, earthenware, and firebrick works, besides manufactures of iron, nails, chains, leather, &c. The grammar-school (1552), at which Samuel Johnson passed a twelvemonth, was rebuilt in 1862; and there are also a corn exchange (1854), county court (1864), and mechanics' institute. Pop. (1851) 7847; (1881) 9737; (1891) 9386.

Stourbridge Fair, Cambridge. See FAIRS.

Stourport, a town of Worcestershire, at the Stour's influx to the Severn, and the terminus of the Staffordshire and Worcestershire Canal, 14 miles by rail N. by W. of Worcester and 4 SSW. of Kidderminster. Dating from 1770, it is a clean, neat place, with manufactures of carpets, iron, glass, &c. Pop. (1851) 2923; (1891) 3504.

Stouthrieff, in the law of Scotland, means robbery committed in a dwelling-house.

Stove. See WARMING.

Stove-plants is another name for hothouse plants—plants which require artificial heat to make them grow and keep healthy in the colder temperate climes. They may be practically classified according to the kind and degree of heat required—from those suitable to the dry hothouse to those fitted to thrive in a cool greenhouse; from tropical orchids to hardy heaths. See PLANT-HOUSES, and the articles on the several species of plants.

Stow, JOHN, one of the earliest and most diligent collectors of English antiquities, was born in London in the year 1525. He was brought up to his father's trade of a tailor in Cornhill, but about his fortieth year abandoned it for antiquarian pursuits with a noble devotion which ought to have ensured him an old age of ease and honour, but which brought him instead only want and beggary. In his eightieth year he was rewarded with letters-patent from James I. authorising him to become a mendicant, or, as it is expressed, 'to collect amongst our loving subjects their voluntary contributions and kind gratuities.' He died 5th April 1605, and was buried in the parish church of St Andrew Undershaft, where his monument of terra-cotta, erected at the expense of his widow, may still be seen. Stow's reverence for the institutions of the past caused him to be suspected of a secret leaning toward popery. The principal works of Stow are his *Summary of English Chronicles*, first published in 1561, and subsequently reprinted every two or three years, with a continuation to the date of each new publication; *Annals, or a General Chronicle of England* (1580); and, most important of all, the invaluable *Survey of London and Westminster* (1598), an account of the history and antiquities of the two cities for six centuries, together with their municipal institutions and forms of government. Besides these original works Stow assisted in the continuation of Holinshed's Chronicle, Speght's edition of Chaucer, &c. His invaluable *Memoranda to Three Fifteenth Century Chronicles* was printed with the text of these by James Gairdner for the Camden Society in 1881. There is a memoir prefixed to the compendious edition of the *Survey* (1842) by W. J. Thoms.

Stowe, HARRIET BEECHER. See BEECHER.

Stowell, WILLIAM SCOTT, LORD, the eldest brother of Lord Eldon (q.v.), was born at Heworth, Durham, 17th October 1745. He was educated at Newcastle, went to Oxford in 1761, and became a college tutor. In 1779 he took the degree of D.C.L., removed to London, and was called to the bar in 1780. Dr Johnson introduced him to the Literary Club. As a barrister at Doctors' Commons he obtained a large practice, and his promotion was rapid. In 1788 he was appointed judge in the Consistory Court, knighted, and nominated a privy-councillor. In 1798 he became judge of the Court of Admiralty. Both as an ecclesiastical and admiralty judge he won high distinction. He wrote no systematic treatise or text-book, but his judgments were admirably reported, and supply the best evidence of his extensive legal learning, his sagacity, and his great literary ability. He was long the highest English authority on the law of nations. He represented Oxford in the House of Commons for twenty years, but he took no part in the business of parliament, although, like his brother, he was a zealous supporter of the Conservative party and the established church. At the coronation of George IV. he was raised to the peerage under the title of Baron Stowell of Stowell Park. In 1828 he retired from the bench, and on the 28th January 1836 he died. See the lives of the two brothers by Surtees cited at ELDON.

Stowmarket, a market-town of Suffolk, on the Gipping, 12 miles NW. of Ipswich. Pop. (1801) 1761; (1891) 5304. Its fine flint-work church (chiefly Decorated) is surmounted by a tower and spire 120 feet high, and the interior contains some interesting monuments, amongst them one to Dr Young—Milton's tutor, and a former vicar. An iron-foundry, chemical and gun-cotton works—the last the scene in August 1871 of a disastrous explosion by which twenty-three persons lost their lives—are in operation, whilst malting and stay-making are also carried on. Burkitt (the commentator) and the poet Crabbe were educated in the town, which, too, was the scene of Godwin's ministry (1778–87). See Hollingsworth, *History of Stowmarket* (1844).

Strabane, a market-town of County Tyrone, Ireland, on the Mourne, 14 miles by rail S. by W. of Londonderry, with which it also communicates by canal and river. Its flax and grain markets are celebrated; and it has two fine churches—Episcopalian and Presbyterian. Pop. 4196.

Strabismus. See SQUINTING.

Strabo, an ancient geographer, born at Amasia in Pontus, probably about 64 B.C., although some authorities make it ten years later. By the mother's side he was of Greek descent, and also closely connected with the Mithridatidæ; of his father's family nothing is known. How the name Strabo ('squint-eyed') must have originated is obvious, but whether any of the family were so called before him is uncertain. Strabo studied under the grammarian Tyrannio at Rome, under Aristodemus at Nysa in Caria, and under the philosopher Xenarchus either at Rome or at Alexandria. He does not appear to have followed any calling, but to have spent his life in travel and study, from which it may safely be inferred that he was well off. He was at Corinth in 29 B.C., ascended the Nile with Ælius Gallus in 24, and seems to have been settled at Rome after 14 A.D., but all we know of the date of his death is that it was after 21 A.D. Of Strabo's great historical work in forty-seven books—from the fifth a continuation to his own time of Polybius—we have only a few fragments; but his *Geographica* in seventeen books has come down to us almost complete. It is a work of great value in those parts especially which record the results of his own extensive observation. 'Westwards,' he says in a passage in the second book, 'I have travelled from Armenia to the parts of Tyrrhenia adjacent to Sardinia; towards the south, from the Euxine to the borders of Ethiopia. And perhaps there is not one among those who have written geographies who has visited more places than I have between these limits.' Yet it must not be supposed that he describes with equal accuracy or fullness all the countries of whose geography he treats. Some he seems to have visited hurriedly, or in passing elsewhither; others he knows like a native. For example, his accounts of Greece, particularly the Peloponnesus, are meagre in the extreme, and of many of the obscurer regions he writes chiefly from hearsay. He makes copious use of his predecessors Eratosthenes, Artemidorus, Polybius, Posidonius, Aristotle, Theopompus, Thucydides, Aristobulus, and many other writers now lost to us, but he strangely depreciates the authority of Herodotus, and quotes few Roman writers except Fabius Pictor and Julius Cæsar. Of the seventeen books of the *Geography* books i.–ii. contain a criticism of former geographers, and the mathematical part of physical geography—the poorest portion of the work; book iii. is devoted to Spain; iv. to Gaul, Britain, and Ireland; v. and vi. to Italy; vii. to the north and east of Europe as far as the Danube; viii.–x. to Greece; xi.–xvi. to Asia; xvii. to Africa. The style is pure and simple. The *editio princeps* of Strabo appeared at Venice in 1516. Good editions are those by Muller and Dübner (1853–56) and Meineke (1852–53). See Marcel Dubois, *Examen de la Géographie de Strabo* (1891).

Stradella, Alessandro, a singer and musical composer, famous both in respect of his music and of his own tragical history. His works, which consist of airs, duets, cantatas, madrigals, sonatas, and the oratorio *San Giovanni Battista* (his most important production), contributed to form the taste of such composers as Purcell and Scarlatti. The dates of his life are altogether uncertain; it can only be affirmed that he lived during the second half of the 17th century. But the facts or events of his life are better ascertained. Stradella, who was renowned for his exquisite voice and polished manner, was engaged by a wealthy Venetian to instruct his mistress in singing. But master and pupil became infatuated with one another and fled to Rome. They were traced thither by two bravos despatched by the Venetian; but both assassins, it is said, were so captivated with the music of Stradella's oratorio, which they heard him conducting whilst lying in wait for him, that they abandoned their object, after betraying to him the plot. Stradella and the lady then fled to Turin. They were found there, and the musician was attacked and left grievously wounded. He recovered and married the lady, and then proceeded to Genoa (1678). The day after his arrival both he and his wife were mortally stabbed in their bedchamber by the emissaries of their unrelenting persecutor.

Stradivari, Antonio, the famed violin-maker of Cremona, lived 1649–1737. He was the pupil of Nicholas Amati, and carried the Cremona type of violin to its highest perfection. See Violin.

Strafford, Thomas Wentworth, Earl of, English statesman, was born on Good Friday, 13th April 1593, in Chancery Lane, London, at the house of his mother's father, Robert Atkinson, a bencher of Lincoln's Inn. The eldest of the twelve children of Sir William Wentworth, he represented a great Yorkshire family, which from before the Conquest had been seated at Wentworth-Woodhouse near Rotherham, and was allied to royalty itself. He grew up a keen sportsman, an apt and diligent scholar, and was sent at an early age to St John's College, Cambridge. In 1611 he was knighted and married; and having thereafter travelled for fourteen months in France and Italy, in 1614 he was returned to parliament for his native county, and succeeded his father in the baronetcy and an estate of £6000 a year. In 1615 he became *custos rotulorum* for the West Riding—a post from which Buckingham sought two years later to oust him; else we know little about him during James I.'s reign save as a generally silent member in three brief parliaments, a strenuous student, and a frequent attendant at the Court of Star-chamber. His first wife, Lady Margaret Clifford, eldest daughter of the Earl of Cumberland, died childless in 1622, and in 1625 he married Lady Arabella Holles, the younger daughter of Lord Clare.

Conscious of his own splendid abilities, and with no great belief in parliamentary wisdom, loyal in his devotion to crown and church, an eager advocate of domestic reforms, and therefore opposed to all wars of aggression, Wentworth in Charles's first parliament (1625) acted with, yet was not of, the opposition; from the second he was purposely excluded by his appointment to be sheriff of Yorkshire. In the July of that same year (1626), after a vain application to Buckingham for the presidency of the Council of the North, he was curtly dismissed from the keepership of the rolls, and for refusing to pay the forced loan he was committed first to the Marshalsea and then to an easy captivity at Dartford. So in the famous third parliament (1628) he impetuously headed the onslaught, not on the king, but on his evil ministers, and pledged himself 'to vindicate—what? New things? No! our ancient, sober, and vital liberties! by reinforcing of the ancient laws made by our ancestors; by setting such a stamp upon them as no licentious spirit shall dare hereafter to enter upon them.' From its meeting on 17th March until 5th May he was the leader of the Lower House; on 7th July the Petition of Right (q.v.), superseding a similar measure of his own, became law; and on the 22d he was created Baron Wentworth, on 10th December Viscount Wentworth, and on the 15th President of the North. As such at York he set himself to govern, to strengthen government with an efficient militia and ample revenue, and to 'comply with that public and common protection which good kings afford their good people.' Towards these ends he used on occasion high-handed methods, which embroiled him, however, chiefly with the gentry. His second wife died in October 1631, leaving a son William, second Earl of Strafford (1626–95, died *s.p.*), and two daughters; and within a twelvemonth he married privately Elizabeth, daughter of Sir George Rhodes, knight.

In January 1632 he was appointed Lord Deputy of Ireland, but it was not till the July of the following year that he landed at Dublin. His plans had, however, been meanwhile carefully matured; and with the subtlety of a Machiavel and the strength of an Englishman he straightway proceeded to coerce Ireland into a state of obedience and well-being unknown alike before and afterwards. He raised the revenue from an annual deficit of £14,000 to a surplus of £60,000, and the customs from £12,000 to £40,000; transformed the army from a rabble of 1300 to an orderly force of 8000; swept the seas of the corsairs infesting them; introduced the cultivation of flax, still Ireland's one flourishing industry; called into existence a docile parliament; did his utmost to cleanse the Augean stable of the Protestant Church; and, whilst seeking 'to draw Ireland into conformity of religion with England,' could yet boast truly that since he had 'the honour to be employed there, no hair of any man's head was touched for the free exercise of his conscience.' The aim of his policy (he and Laud called it 'Thorough') was to make his master 'the most absolute prince in Christendom;' and 'the choice for Ireland in the 17th century did not lie between absolutism and parliamentary control, but between absolutism and anarchy.' The words are Professor Gardiner's, and he adds that 'if Wentworth be taken at his worst, it is hardly possible to doubt that Ireland would have been better off if his sway had been prolonged for twenty years longer than it was.' Wentworth taken at his worst should be Macaulay's Wentworth—the killer of his first wife, the debaucher of women, the 'wicked earl,' the 'first Englishman to whom a peerage was a sacrament of infamy,' the 'lost Archangel, the Satan of the apostasy,' who from the time of that apostasy received, like fallen Lucifer, a fresh name, Strafford. By this last amazing blunder—the schoolboy might detect it, and yet it has lived for upwards of sixty years—Macaulay's ignorance may be fairly gauged, the falsity of his first two charges estimated. None the less, by Macaulay's verdict has Wentworth been widely condemned. One turns from it to Wentworth's own correspondence, and there stand revealed his tenderness for his family, his love of harmless amusements, his hatred of gaming and drunkenness, his contempt of courtiers, and the maladies which constantly beset him—fever, ague, gout, and the stone—and to which his choleric temper is largely ascribable. He was not otherwise faultless, though many of his errors—e.g. in the matter of monopolies and of the proposed plantation of Connaught—were errors of the age. He was too masterful and self-reliant, too heedless of the means towards his end, intolerant of opposition to his will. One instance of his methods must suffice. Lord Mountnorris, vice-treasurer of Ireland, was for words rashly spoken court-martialed, and sentenced to death. The sentence was never meant to be carried out; in fact, Wentworth added, 'I would rather lose my hand than you should lose your head,' and Mountnorris was simply stripped of his offices. He deserved to be stripped of them; still, this was not the way to get rid of an opponent.

Till February 1637 Charles seems never to have applied to Wentworth on questions of general policy, and then, when he sought his approval of a foreign war, he was met with dissuasion. Nor till September 1639 did Wentworth become the king's principal adviser, the mark of the royal favour being his elevation to the earldom of Strafford and the dignity of Lord-lieutenant of Ireland (January 1640). It was all too late then. The rebellion, provoked in Scotland by Charles's unwisdom, was spreading to England; and Pym and his fellows judged rightly that Strafford was the one obstacle to their triumph. His Irish parliament was all subserviency, but he a week after the meeting of the Long Parliament in November was impeached of high-treason and lodged in the Tower. In the great trial by his peers, which opened in Westminster Hall on 22d March 1641, Strafford, broken though he was by sickness, defended himself with a fortitude, patience, and ability that moved even his accusers, whilst alarming them. The twenty-eight charges, covering 200 folios, at most amounted to 'cumulative treason;' the gravest of them, his having counselled the king that 'he had an army in Ireland which he could employ to reduce *this kingdom*' (query England or Scotland), was supported by only one witness, his personal enemy, Vane. Four others who should have heard the words declared that they had not heard them. To the Lords the question was his guilt or innocence, to the Commons his condemnation; their spirit was shown in St John's declaration the 'we give law to hares and deer, as beasts of chase, but knock foxes and wolves on the head as they can be found, because they be beasts of prey.' Accordingly, on 10th April the 'inflexibles'—Pym and Hampden were not of their number—dropped the impeachment for a bill of attainder, declaring that treason which could not be proved to be treason. The bill passed a third reading by 204 votes to 59 in the Lower House, by 26 to 19 in the Upper ('Stone dead hath no fellow,' said Essex); and on 10th May it received the royal assent. Strafford had written to Charles releasing him from his reiterated pledge that he should not suffer in life or honour or fortune; and Charles at last accepted the release. 'Put not your trust in princes'—the cry was wrung from Strafford; then he prepared himself quietly for death. They would not let him see his old friend Laud; but he knelt for his blessing under the prison window as he passed to the scaffold. The lieutenant of the Tower would have had him take coach lest the mob should tear him to pieces, but 'No,' was his answer, 'I dare look death in the face, and I hope the people too.' And so he died valiantly, Christianly, on Tower Hill, 12th May 1641, and was buried at Wentworth-Woodhouse. His death was followed by the abolition of Episcopacy, monarchy, parliament itself.

We know Strafford better now than his contemporaries could possibly know him, through his *Letters and Correspondence*, edited by Knowler (2 vols. 1739), and Whitaker's *Life and Correspondence of Sir George Ratcliffe* (1810). Ratcliffe (1593-1657) for years was Strafford's confidant; and his brief 'Essay towards the Life of my Lord Strafforde,' appended to Knowler's work, is one of our chief authorities. Modern Lives are by John Forster (*Emin. Brit. Statesmen*, vol. ii. 1836: Dr Furnivall in Berdoe's *Browning Cycl.* asserted that this was completed 'on his own lines' by Robert Browning, and as Browning's it was edited for the Browning Soc. by Mr C. H. Firth in 1892), J. B. Mozley (*Essays Hist. and Theological*, 2d ed. 1884), Elizabeth Cooper (2 vols. 1874), and H. D. Traill (1889). See also the articles CHARLES I. and LAUD, with works there cited; Browning's strangely unhistorical *Strafford: a Tragedy* (1837); ed. by *Miss Hickey and Prof. S. R. Gardiner, 1884*); and John Smith's *Catalogue Raisonné of the Works of Dutch Painters* (vol. iii. 1831) for a list of the half-dozen portraits by Van Dyck, in which the 'lion-faced' earl still lives for us. Strafford's eldest daughter Anne married Edward Watson, second Baron Rockingham and first Earl of Rockingham, the ancestor of Earl Fitzwilliam; his second daughter Arabella married the Hon. Justin M'Carthy, the Earl of Clancarty's third son, whom James II. created Viscount Mountcashell. A son and a daughter by his third wife both died unmarried.

Strain and **Stress.** A strain is any change of form or bulk of a portion of matter either solid or fluid. The system of forces which sustains the strain is called the stress. When a body is so strained that parallel lines remain parallel lines and parallel planes remain parallel planes, the strain is said to be homogeneous. Any cubical portion becomes a parallelopiped with angles, in general, other than right angles; and any spherical portion becomes an ellipsoid. The principal axes of this ellipsoid were originally mutually perpendicular diameters of the sphere. Clearly one of them must be the direction of greatest elongation (or least contraction), and another must be the direction of least elongation (or greatest contraction). These directions are the principal axes of the strain. A special case of the homogeneous strain is the isotropic strain, in which all lines suffer equal elongations—i.e. unit-length in any direction changes by the same amount. Here there is simple change of volume without any distortion; and the associated stress is of the type of a hydrostatic pressure. Now the most general homogeneous strain involves distortion as well as change of volume. If the strain is small we may decompose the complete strain into these two types of strain, which, as explained under Elasticity (q.v.), have to do with two quite distinct coefficients—viz. the Rigidity (q.v.) and the bulk modulus (see COMPRESSIBILITY). A distortion is a strain which involves no change of volume; and any distortion can always be decomposed into a number of shears or simple distortions. The simplest representation of a shear is given by the slight deformation of a circle into an ellipse of the same area. The major and minor axes of the ellipse are the principle axes of the shear, which is completely determined when its plane, axes, and elongations or contractions along these axes are given. A shear may also be represented by the sliding action of layer over layer which transforms a square into a parallelogram of the same area. Corresponding to a shear is the shearing stress, whose ratio to the shear is called the rigidity. It is obvious that in bending a bow or twisting a rod (see TORSION) we are producing strains which are not homogeneous; but by considering very small portions we are able to discuss the relations holding between the strains and corresponding stresses as if the strains were homogeneous.

When a body is perfectly elastic the relation between stress and strain is unchanging; in other words, to sustain the strain the same stress must be constantly applied. All solids, however, may be strained to such a degree that the strain may be supported by a weaker stress than that which produced the strain at first. Or, when a given stress is kept applied, the body may gradually alter its condition of strain as time goes on. Solids, in short, are found to possess Viscosity (q.v.), in virtue of which they yield slowly to a steady stress. Thus Tresca has caused metals to flow through ducts by application of great pressure. See STRENGTH OF MATERIALS.

Bodies may be strained by the action of other agents than mechanical forces. The most familiar example of this is the change of bulk which accompanies change of Temperature (q.v.). Electrification also produces changes of volume. Again, the magnetic metals, iron, nickel, and cobalt, undergo very complicated strains when magnetised in various ways. In all these instances there is always a reciprocal effect, a particular straining producing thermal, electric, or magnetic changes.

Straits Settlements, a British colony in the East Indies, consists (since 1867) of settlements on the Straits of Malacca, or rather on the Malay Peninsula—viz. Singapore, Malacca, Penang, Keeling Islands (since 1886), and Christmas Island (since 1889). For particulars of these, see the respective articles. The total area is 1542 sq. m. and the total pop. (1881) 423,384; (1891) 506,577. About 150,000 of these are Chinese, and a large number natives of India; of these last there arrive about 18,000 every year, though nearly as many leave again. The principal productions of the colony are tin, gambier, tapioca, rice, sugar, pepper, and other spices. The trade is largely a transit one; and the exports reach approximately an annual value of £7,500,000, the imports of £29,000,000; but both are increasing at a rapid rate. There are a number of native dependent states, the salient particulars regarding which are given here, while the more important states are treated in separate articles.

State.	Made a British Protectorate in	Area, sq. m.	Pop (1891).	Annual value of Imports.	Annual value of Exports.
Perak	1874	7,950	212,997	£1,101,000	£608,000
Selangor	1874	5,000	81,421	1,098,000	436,700
Sungei Ujong	1885	660	23,602	88,600	64,000
Negri Sembilan	1889	2,000	41,617	16,000	22,000
Pahang	1888	15,000	52,803	..	..
Total		30,610	412,440	£2,303,600	£1,130,700

The more notable productions of these states are tin, rice, coffee, sugar, tea, cinchona. Tin is chiefly mined in Perak by Chinese, and worked at the mines, and at Singapore and Penang. The climate of all these states and districts is pretty uniform, though high, the mean being 82·5° F. The rainfall is distributed with tolerable regularity over the whole twelve months, in which period it ranges from 84 to 110 inches. See the map in Vol. II. p. 562.

Stralsund, a seaport of Prussia, is situated on a narrow strait called the Strela Sound, which divides the mainland from the island of Rügen, and 67 miles by rail NW. from Stettin. It forms an island, connected with the mainland by bridges. Down to 1873 the place was a fortress of the first class. Many of the houses are finely gabled, which gives the town a quaint and ancient look. The most interesting building is the town-house (1306), with a museum of antiquities from the island of Rügen. Stralsund carries on a large export trade in malt, corn, fish, wool, coal, groceries, &c., and manufactures leather, sugar, starch, oil, and cards. Pop. (1890) 27,820. Stralsund was founded in 1209, and became one of the most important members of the Hansa. During the Thirty Years' War it successfully withstood a terrible siege (1628) by Wallenstein; but in 1678 it capitulated to the Great Elector after a furious bombardment. It again opened its gates to Prussia and her allies in 1715, to the French in 1807, and to the Danes and others in 1809. The town was held by the Swedes from 1628 to 1814; in the year following (1815) Denmark gave it up to Prussia.

Stramonium. See THORN-APPLE.

Strange, SIR ROBERT, engraver, was born in the Mainland of Orkney on 14th July 1721. He had tried sailoring and a law-clerkship with an elder half-brother in Edinburgh, when in 1735 he was apprenticed for six years to an English engraver there, Richard Cooper. His apprenticeship ended, he fell in love with a young Jacobite lady, Isabella Lumisden, and for her sake in 1745 espoused the cause of Prince Charles Edward, engraving not only his portrait but his bank-notes, and enlisting as a private in the prince's life-guards. He fought at Culloden, escaped his pursuers by hiding beneath his sweetheart's ample-hooped gown, in 1747 married her, and next year repaired to Rouen and thence to Paris, and studied under Descamps and Lebas. In 1750 he returned to Britain, and settling in London soon attained the very highest rank in his profession. On a second visit to the Continent (1760-65), to execute engravings after the old masters, his eminence was recognised by the academies of Paris, Rome, Florence, Bologna, and Parma, which all conferred on him the honour of membership; and subsequently, in 1787, he was knighted, having made peace with the reigning house by engraving West's picture of the apotheosis of George III.'s children, Octavius and Alfred. He died a wealthy man on 5th July 1792, his wife surviving him by fourteen years.

See Dennistoun's *Memoirs of Sir Robert Strange* (2 vols. 1855); the Life by the Rev. F. Woodward prefixed to *Twenty Masterpieces of Strange* (1874); and also the Introduction to Marshal Keith's *Memoir* (Spalding Club, 1843).

Strangford, VISCOUNT. Percy-Clinton-Sydney Smythe was born 31st August 1780, studied at Trinity College, Dublin, and entered the diplomatic service. He succeeded to the title as sixth viscount in 1801, was secretary of legation at Lisbon, and later ambassador successively to Portugal, Sweden, Turkey, and Russia. He was raised to the English peerage as Baron Penshurst in 1825, and died 29th May 1855. His translation of the *Rimas* of Camoens he published in 1803.—His youngest son, PERCY-ELLEN-FREDERICK-WILLIAM SMYTHE, was born at St Petersburg, 26th November 1825, and had his education at Harrow and Merton College, Oxford. He entered the diplomatic service, early acquired an unexampled command of languages, and served as Oriental secretary during the Crimean war. In 1857 he returned home to succeed as eighth and last viscount, thereafter lived mostly in London, immersed in philological studies ranging from Turkish, Persian, Arabic, and Afghan to Basque, Celtic, and Lithuanian, and died there, 9th January 1869. In spite of his phenomenal acquirements, he wrote little more than a few *Saturday*, *Pall Mall*, and *Quarterly* articles. His *Selected Writings: Political, Geographical, and Social*, was edited by his widow (2 vols. 1869), who also published his *Letters and Papers upon Philological and Kindred Subjects* (1878). See Fonblanque's *Lives of the Lords Strangford* (1878).

Strangles is a contagious eruptive disorder peculiar to young horses. It is ushered in by sore throat and cough, a muco-purulent nasal discharge, and the eruption of a swelling in the space between the branches of the lower jaw. In a few days this swelling comes to a head, bursts, and in favourable cases the patient is soon well again. From exposure to cold, poverty, or other causes, the swelling, however, occasionally appears in less favourable situations, as about the glands lying within the shoulder, in those of the groin, or even in those of the mesentery. Such irregular cases are apt to be protracted, accompanied by much weakness, and sometimes prove fatal. Bleeding, physic, and irritant dressings are injurious. Good food and nursing, with fomentations to the throat and steaming of the head, favour the healthier maturation of the swelling. When there is debility, coax the animal to eat by offering him at short intervals small quantities of scalded oats, malt, bran, or green food, and allow him several times daily a pint of sound ale if he will drink it, but do not force it upon him, as the throat is often irritable and the animal might be choked.

Strangulation may be defined as an act of violence in which constriction is applied directly to the neck, either around it or in the forepart, in such a way as to destroy life. This definition obviously includes hanging, which differs from other forms of strangulation only in that the body is suspended. The direct cause of death in the great majority of cases is arrest of the respiration owing to pressure on the windpipe—i.e. asphyxia. If much violence is used, it may be produced by direct injury to the upper part of the spinal cord from fracture or dislocation of the cervical vertebræ (as is now the rule in execution by hanging), or by syncope from shock, and in such cases must be almost instantaneous. On the other hand, if the constriction is so applied as to compress the great vessels in the neck and not the windpipe, as may happen in 'garotting,' it is due to coma, and is somewhat slower than in cases of asphyxia. Or if both vessels and windpipe are compressed, coma and asphyxia may both contribute to cause death.

The internal appearances of the body after death are those of Asphyxia (q.v.), with specially marked congestion of the brain; the most constant external appearances are congestion of the face, with prominence of the eyes and protrusion of the tongue, and marks on the neck corresponding to the cord or other constricting agent. The latter are most evident and the injuries to the neck most severe in homicidal cases. Death by hanging (excepting judicial executions) is almost always suicidal; by other forms of strangulation it also is frequently suicidal, but often homicidal. Accidental strangulation in any form is rare.

When suspension of the body has not continued for much more than five minutes, and the parts about the neck have not suffered violence, there is a probability that resuscitation may be established; although many cases are recorded when after only a few minutes' suspension it has been found impossible to restore life. Moreover, if a person who has hanged himself has been cut down sufficiently soon to allow of the respiratory process being restored, he is by no means safe: death often taking place from secondary effects at various periods after the accident. It is believed that unconsciousness comes on very rapidly, and death takes place without causing any suffering; the violent convulsions that are so often observed being similar to those which occur in epilepsy. In homicidal cases, however, the appearance of the face sometimes indicates much distress. A man named Hornshaw, who was on three occasions resuscitated from hanging—a feat which he performed in London for the amusement of the public—stated that he lost his senses almost at once; and other persons who have been restored state that the only symptoms of which they were conscious were a ringing in the ears, a flash of light before the eyes, then darkness and oblivion. The treatment to be adopted after the patient has been cut down may be briefly summed up as follows: Exposure to a free current of air, cold affusion if the skin is warm, the application of ammonia to the nostrils, of mustard poultices to the chest and legs, and of hot water to the feet, and the subsequent abstraction of blood if there should be much cerebral congestion; above all, artificial respiration should be used if natural breathing do not at once commence. From the post-mortem appearances, together with circumstantial evidence, the medical practitioner is not unfrequently called upon to decide such questions as these: Was death caused by hanging, or was the body suspended after death? Was the strangulation the result of accident, homicide, or suicide? In case of strangulation from other causes than that of hanging the post-mortem symptoms are similar, but the injury done to the parts about the neck is commonly greater. In manual strangulation the external marks of injury will be in front of the neck, about and below the larynx; and if death has been caused by a ligature the mark round the neck will be circular, whereas in hanging it is usually oblique. The internal appearances are much the same as in the case of hanging. See Taylor's or other text-book of Medical Jurisprudence.

Strangury. See URINE.

Stranraer, a royal burgh and seaport of western Wigtownshire, beautifully situated at the head of Loch Ryan, 73 miles WSW. of Dumfries by rail. The buildings are a 16th-century castle in which the bloody Claverhouse lived as sheriff, the new town-hall and court-house (1872–73), and several handsome churches. There are no manufactures, but considerable trade in farm-produce. Loch Ryan affords fair fishing, but not now in oysters. There is a small but constant shipping-trade in bottoms belonging to the town, and a commodious mail-steamer plies daily between Stranraer and Larne in Ireland, the 'short-sea passage' merely taking about 2¼ hours, only half being in open channel. Pop. of royal burgh (1871) 5977; (1881) 6415; (1891) 6171. Till 1885 Stranraer returned one member with Wigtown (q.v.).

Straparola, GIOVAN FRANCESCO, was born near the end of the 15th century at Caravaggio, about half-way between Milan and Cremona. In

1550 he published at Venice *Tredeci piacevoli notti*, the second part at the same place in 1554. This famous work was a collection of stories in the style of the *Decameron*, grouped round an imaginary incident. Francesca Gonzaga, daughter of Ottaviano Sforza, Duke of Milan, on account of commotions in that city, retires to the island of Murano, near Venice, where, surrounded by a group of brilliant ladies and gentlemen, she passes the time listening to stories related by the company. Thirteen nights are thus spent, and seventy-four stories told, each followed by an enigma, when the approach of Lent brings an interruption. These stories are derived from the most various sources; twenty-four are borrowed from Jerome Morlini, fifteen from Boccaccio, Sachetti, Brevio, Ser Giovanni, the *Fabliaux*, the *Golden Legend*, and the *Romance of Merlin*. Six are of plain oriental origin, and may be found in the *Panchatantra*, *Forty Viziers*, *Siddhi Kür*, and *Thousand and One Nights*. Twenty-nine stories remain, and of these twenty-two are genuine folk-tales. Two of Straparola's stories found a wider immortality in Perrault's 'Peau d'Ane' and 'Le Chat Botté;' and many of Madame d'Aulnoy's fairy-tales, as well as others in the *Cabinet des Fées*, are mere translations. Straparola's book passed through sixteen editions in twenty years; a French translation of the first book by Jean Louveau appeared in 1560, reprinted in 1573, along with the second book as translated by Pierre de Larivey (*Les Facétieuses Nuits de Straparole* in P. Jannet's 'Bibliothèque Elzevirienne,' 2 vols. 1857; new ed. of Jouaust, with preface by Gustave Brunet, 1882). Many of Straparola's stories are *facetious* in its narrowest sense; but at least they are no worse than their contemporaries. The work was prohibited by the church in 1605; yet another reprint appeared at Venice so soon after as 1608.

A German translation of eighteen out of the twenty-two popular tales, with valuable notes, by F. W. Val. Schmidt, appeared at Berlin in 1817. See the *Inaugural Dissertation on Straparola*, by F. W. J. Brakelmann (Gottingen, 1867); also Liebrecht's translation of Dunlop's *History of Fiction* (1851).

Strasburg (Ger. *Strassburg*, Fr. *Strasbourg*), formerly the capital of the French department of Bas-Rhin, but since 1871 capital of the German imperial territory of Alsace-Lorraine, stands on the river Ill and the canals connecting the Rhine with the Rhone and the Marne, 2 miles from the left bank of the Rhine, and 300 miles E. of Paris. The citadel, originally built by Vauban (1682–84), was demolished by the Germans during the bombardment of 1870, but since then they have rebuilt it and strengthened the fortifications with some fourteen detached forts on the adjacent heights, so that Strasburg now ranks as a first-class fortress of great strength. Its position near the borders of France, Germany, and Switzerland is favourable to its commerce, and gives it great strategic importance. The most celebrated building in the city is the cathedral or minster, founded in 1015 or in 1179, but principally built between 1277 and 1439; some of the oldest parts are Romanesque (portions of choir and transept), but the church as a whole is one of the sublimest specimens of Gothic architecture in existence. The principal architect (to whom most of the glorious western façade is due) was Erwin von Steinbach (fl. 1318). Only one of the two towers was completed, with a spire of open stone-work (1439); it is 466 feet high. The minster has a remarkable astronomical clock dating from 1838–42; in it are portions of an older one made in 1571, but there was a remarkable clock here in the 14th century. In the present one are, besides a complete planetarium and perpetual calendar, many automaton figures—angels which strike the quarters, twelve apostles which come forth at noon and pass in procession before a figure of Christ, and a cock which crows at stated times. In the church are also a magnificent rose-window (42 feet across), a fine pulpit, and grand stained glass. The damage done to the structure during the siege of 1870 was carefully repaired. Other notable buildings are the Protestant church of St Thomas, with the tomb of Marshal Saxe, the imperial palace, the library (formerly the castle, and then the episcopal palace), the new university, the public buildings of the province, and the arsenal. The university of Strasburg was the only French university besides Paris with the full complement of faculties. Founded in 1621, on the basis of the academy of Jean Sturm (q.v.), it became specially famous in the branches of medicine and philology, but was broken up during the Revolution. In 1803 a Protestant academy was established with ten chairs; and five years later Napoleon founded an imperial academy with faculties of law, medicine, physical science, and philosophy; in 1819 a partial fusion of these academies took place. The university was reorganised as a German institution in 1872, is equipped with new university buildings (1884), magnificent laboratories, &c., and has more than 100 teachers and 900 students. The famous library, with nearly 200,000 volumes and precious *Incunabula* (q.v.), was entirely destroyed by fire during the bombardment in 1870, but was replaced by a new collection that has now swelled to 600,000 volumes. The trade of Strasburg, especially its transit trade, is very extensive, and it has a great variety of manufactures—beer, patés de foie gras, leather, cutlery, engines, musical instruments, jewellery, tobacco, furniture, chemicals, fancy articles, &c. Pop. (1880) 104,471; (1890) 123,566—one-half Catholics.

Strasburg, the *Argentoratum* of the Romans, was colonised by them during the reign of Augustus. Here Julian won a great victory over the Allemanni in 357 A.D. The name *Stratisburgum* first appears in the 6th century. It became a free town of the German empire in the 13th century, and both then and in the early part of the 15th century occupied a prominent position in respect of culture and enlightenment. In 1681 it was seized by Louvois, at the command of Louis XIV., in a time of profound peace, and was confirmed to him by the treaty of Ryswick, but retained the quaint appearance of a German imperial city. On September 28, 1870, after a siege of seven weeks, Strasburg surrendered to the Germans.

See Seinguerlet, *Strasbourg pendant la Revolution*; German works by Apell (Berl. 1884) and Krieger (Strasb. 1885); for the siege, Wagner (3 vols. Berl. 1874–77); also the article ALSACE.

Strata Florida (Latinised from Ystrad Fflûr, 'Plain of the Fflûr'), the ruins of a Cistercian abbey founded in 1164, 17 miles SE. of Aberystwith. Little of the building but a Norman archway and part of a wall are now standing; but excavations in 1857–88 laid bare the foundations and some fine tiled pavements. See the monograph by S. W. Williams (1889).

Strategy has been defined by military writers as the 'science of generals,' 'the art of making war on the map,' or 'the art of rightly directing masses of troops towards the object of the campaign;' it is dependent upon the due consideration of everything that can possibly influence the campaign. Roughly speaking, strategy directs the movements of troops until contact with the enemy is imminent. From that moment all combinations and manœuvres are classed as *Tactics* (q.v.), until perhaps the opposing armies become again sufficiently separated for strategy to be employed. The object of strategy is to bring an adversary into such a position that the chances of victory will be against him, and defeat will entail disasters beyond the loss of the battle. Strategy will be offensive or defensive according to political or geographical considerations and the relative strength or mobility of the belligerents. The former will give all the advantages of the initiative to the commander who can adopt it. He will by invading the enemy's country consume his supplies, and spare his own the horrors of war. He will be able to make and carry out his plans unimpeded by his opponent, who will be ignorant where the mass of his troops are concentrated, and so must await the attack in a more or less scattered and therefore dangerous condition. Defensive strategy, on the other hand, has advantages in facility of supply and transport, freedom of movement, and power to utilise obstacles. Also a defender becomes stronger as he retires, whilst his assailant grows weaker as he advances, and must leave troops behind him or bring fresh forces into the theatre of war in order to guard his *base of operations*, where his supplies collect, and the *lines of communication* by which they reach him.

The assailant will endeavour to reach his *objective point*—i.e. some place, generally the capital city, the capture of which will end the campaign or enable him to make a further advance. His troops must be so disposed as to be able to concentrate on important points in numbers superior to the enemy. The latter, on the other hand, will endeavour to do the same, and also to operate against his adversary's communications without exposing his own. As he probably can shift his base and lines of communication more easily than the invader, some advantage will here accrue to him. Also, his troops being generally more concentrated, he can probably act on *interior lines*—e.g. if of four equidistant armies three were on the circumference of a semicircle and the fourth at the centre, it is evident that the latter might defeat any one of the former before it could be reinforced by either of the others.

Perhaps the most brilliant example of this was shown by Napoleon I. in the first part of the campaign of 1814. Towards the end of January of that year he with 70,000 young conscripts was at Châlons; to the south 160,000 Austrians and Russians under Schwarzenberg were advancing from Basel along the valley of the Seine, and to the north 60,000 Prussians under Blücher along the Marne from Mannheim, the objective of both being Paris. Napoleon after the indecisive battle of Brienne was defeated by Schwarzenberg at La Rothière. The latter moved slowly, and Blücher, thinking to gain Paris first, moved his corps by several roads. Napoleon leaving 20,000 men under Oudinot and Victor to hold the passages over the rivers, and to delay Schwarzenberg still further, carried the remainder rapidly against the scattered Prussians, defeating them in detail at Champaubert, Montmirail, and Château-Thierry, obliging Blucher to retire to Châlons. He then turned upon Schwarzenberg, beat him, and had driven him back to Troyes by the end of February. The allies were so dispirited that they asked for an armistice. See Lieut. J. Bigelow, U.S. cavalry, *The Principles of Strategy* (1891), with other works cited at TACTICS.

Stratford, a thriving town of Essex, on the Lea, 4 miles ENE. of London. It had a Cistercian abbey (1134) and the Empress Matilda's three-arched, bow-shaped bridge (removed in 1839); now it has a handsome town-hall (1869), and is the seat of various and extensive manufactures. Pop. (1851) 10,586; (1871) 23,286; (1881) 38,606; (1891) 42,982. On the opposite side of the Lea is the parish of Bow, or Stratford-le-Bow. Pop. (1851) 4626; (1871) 26,055; (1891) 40,378.

Stratford, a port of entry and capital of Perth county, Ontario, on the Avon, 88 miles by rail W. of Toronto, with railway-shops, woollen-mills, and manufactories of machinery, farming implements, boots and shoes, &c. Pop. 8239.

Stratford de Redcliffe, SIR STRATFORD CANNING, K.G., G.C.B., first Viscount, the famous ambassador, known as 'the Great Elchi,' was descended from the Cannynges of Bristol, but was born in London, 4th November 1786, the fifth and youngest child of Stratford Canning, a merchant, and was first cousin to George Canning the statesman. He was educated at Eton, and proceeded in due course as scholar to King's College, Cambridge, where, however, his terms were interrupted by diplomatic appointments, and he did not take his degree till 1812, when it was granted by royal mandamus. In 1807 he acted as précis-writer to his cousin at the Foreign Office, and in the same year went as second secretary with Merry's mission to Copenhagen. In 1808 he was appointed first secretary to Sir Robert Adair's embassy to Constantinople, and succeeded him as minister-plenipotentiary in 1810. His duty was to counteract the influence of France at the Porte, and he succeeded on his own initiative and without the smallest countenance from his government or the Foreign Office in negotiating the important treaty of Bucharest in 1812 between Russia and Turkey, who were then at war, just in time to release the Russian army of the Danube and enable it to fall upon Napoleon on his retreat from Moscow. This signal service was recognised by Lord Castlereagh's government, who appointed him minister in Switzerland, 1814; there he assisted in framing the Swiss constitution, and visited Vienna as commissioner during the famous Congress of 1815. He resigned the mission in 1819, and was immediately appointed minister to the United States, and remained at Washington till 1823. In the following year he was sent on a special mission to Vienna and St Petersburg, connected with the Greek question, and in 1825 went to Constantinople as full ambassador. Here he witnessed the massacre of the Janizaries, and exerted himself on behalf of the insurgent Greeks. After the battle of Navarino the embassy was necessarily withdrawn, and, in consequence of serious differences with Lord Aberdeen on the policy to be adopted towards Greece, Canning resigned his post in 1828, but his services were recognised by the decoration of the Grand Cross of the Bath. In 1831 he was again sent to Constantinople on a special mission, to draw the boundaries of the new kingdom of Greece, and on his return was gazetted ambassador to St Petersburg; but the czar, without alleging a reason, declined to receive him—probably because he dreaded so keen an eye at close quarters. In 1833 Sir Stratford went to Madrid on a special mission relating to the Portuguese succession, but his efforts were, as it was foreseen they must be, fruitless. During the intervals in his diplomatic career he sat in the House of Commons as a moderate Tory, or 'Stanleyite,' for Old Sarum, 1828-30; Stockbridge, 1831-32; and King's Lynn, 1834-42; but failed to make his mark as an orator or a debater. From 1842 to 1858 he was again ambassador at Constantinople, and built up that extraordinary influence so eloquently described by Kinglake, which gained him the name of the 'Great Elchi.' He induced the sultan to inaugurate a series of reforms, and to authorise numerous improvements in the condition of the Christian rayas, culminating in the celebrated Hatti-Humayun of 1856, which may be termed the Magna Charta of the Christian subjects of the Porte. His diplomatic skill and his unbounded influence over the Turks were never seen to greater advantage than in 1853, in his negotiations with Prince Menschikoff, the Russian special ambassador, concerning the dispute about the Holy Places and the Russian claim for predominating influence on behalf of the Christians of Turkey. His strenuous and unflagging exertions to preserve peace were, however, defeated by the obstinacy of the Czar Nicholas and the vacillating weakness of Lord Aberdeen's government; the war which ensued between Russia and Turkey involved England and France; and the result was the expedition to the Crimea, and the siege of Sebastopol. At the close of the war, after obtaining the proclamation of the Charter of Reform, Lord Stratford, who had been created a viscount in 1852, resigned his embassy in 1858, at the age of seventy-one, and a diplomatic career of unexampled distinction, lasting over half a century, came to an end. Stratford de Redcliffe was the last of the old style of semi-royal and half-independent ambassadors: the telegraph-wire has made ministers of his mettle and character impossible if not superfluous. After his retirement he occasionally took part in the debates on foreign policy in the House of Lords, and devoted part of his leisure to the writing of poetry, which had been a favourite occupation with him since he wrote a fine poem on *Buonaparte*, which attracted the admiration of Byron, in 1814. Some articles on the *Eastern Question* were collected after his death and edited by Dean Stanley. He was created a Knight of the Garter in 1869 at Mr Gladstone's recommendation, and died in the full enjoyment of his mental powers though at the great age of almost ninety-four, 14th August 1880. His statue was erected in Westminster Abbey in 1884.

See *Life of Stratford Canning, Viscount Stratford de Redcliffe*, by the present writer (2 vols. 1888; 1 vol. 1890).

Stratford-on-Avon, Shakespeare's birthplace, is a pleasant town of Warwickshire, 8 miles SW. of Warwick, 22 SSE. of Birmingham, and 110 NW. of London. It stands on the right bank of the quiet Avon, which here is spanned by the 'great and sumptuous bridge' of fourteen pointed arches, 376 yards long, that was built by the Lord Mayor of London, Sir Hugh Clopton, who died in 1496. 'Shakespeare's House,' where the poet was born on 23d April 1564, in Henley Street, is national property, having been bought for £3000 in 1847, and restored in 1858-59; here are a Shakespeare museum, the 'Stratford portrait,' and the signatures of Byron, Scott, Tennyson, Thackeray, Dickens, &c. King Edward VI.'s grammar-school, where Shakespeare was educated, was founded by Thomas Jolyffe in the reign of Edward IV.; it occupies the upper story of the old guildhall, and was restored in 1892. The 'New Place,' built by Sir Hugh Clopton in the reign of Henry VII., was purchased by Shakespeare in 1597, and here he died on 23d April 1616; here, too, Queen Henrietta Maria stayed in 1643. It (or rather its successor, 1703) was wantonly razed in 1759 by a vicar of Stratford, who also felled the poet's mulberry, beneath which Garrick was regaled in 1742; but its site has also become national property since 1861. And lastly, uprearing its spire above the lime-trees, there is the beautiful cruciform church, Early English to Perpendicular in style, having been gradually rebuilt between 1332 and 1500 by Archbishop John de Stratford, Dr Thomas Balsall, and Ralph Collingwood. In the chancel, whose two years' restoration was completed in 1892, is Shakespeare's grave, with the portrait bust (1616) by Gerard Janssen or Johnson, Anne Hathaway's grave, and the American stained-glass window of the 'Seven Ages.'

The Shakespeare Fountain (1887) was also erected by an American, Mr George W. Childs (q.v.); the red-brick Shakespeare Memorial Theatre, seating 800 spectators, was built in 1877-79 at a cost of £30,000. In the neighbourhood are Shottery, with Anne Hathaway's cottage (purchased for the nation in 1892 for £3000); Luddington, where tradition says she was married; Charlecote, the seat of the Lucys; Clopton, with memories of the Gunpowder Plot; and Welcombe Hill, crowned by an obelisk (1876), 124 feet high, to a Manchester M.P. In Stratford itself still remain to be noticed the chapel of the Guild of the Holy Cross (13th century; the chancel rebuilt about 1450, and the rest by Sir Hugh Clopton); the half-timbered house of the Harvards (1596); the town-hall (1633; rebuilt 1768-1863), with Gainsborough's portrait of Garrick; the corn exchange (1850); the market-house (1821); the College school (1872); a Roman Catholic church by Pugin (1866); and a hospital (1884). Before 691 a Saxon monastery stood at Stratford-on-Avon, which was incorporated in 1553. It is an important agricultural centre; still, its chief prosperity depends on the 20,000 or so pilgrims who visit it yearly. Pop. (1851) 3372; (1891) 8318, an increase largely due to the extension of the borough boundary in 1879.

See the 'Shakespeare's Birthplace, &c. Trust Act, 1891' (incorporating the Trustees and Guardians of Shakespeare's House, the New Place, &c), Washington Irving's *Sketch Book* (1821), Hawthorne's *Our Old Home* (1863), Wheeler's *History and Antiquities of Stratford-on-Avon* (1806), nine works by J. O. Halliwell-Phillips (1863-85), S. L. Lee's *Stratford-on-Avon from the Earliest Times to Shakespeare* (1884), and other books cited at AVON and SHAKESPEARE.

Strathaven, a town of Lanarkshire, 1 mile W. of Avon Water, and 16 miles SSE. of Glasgow. On the north side is the picturesque ruin of Avondale Castle, and 5 to 7 miles south-west are the battlefields of Drumclog and Loudoun Hill. Pop. (1851) 4274; (1891) 3478. See Gebbie's *Sketches of Avondale* (1880).

Strathclyde. In the 8th century the ancient confederacy of the Britons was broken up into the separate divisions of Wales and English and Scottish Cumbria. Scottish Cumbria, otherwise called Strathclyde, thenceforth formed a little kingdom, comprising the country between Clyde and Solway, governed by princes of its own, and having the fortress-town of Alclyde or Dumbarton for its capital. Becoming gradually more and more dependent on Scotland, it was annexed to the Scottish crown at the death of Malcolm I., on failure of the line of native sovereigns. Edgar bequeathed Strathclyde to his youngest brother David, again separating it from the crown of Scotland, which went to his intermediate brother, Alexander I. David held it throughout Alexander's reign in spite of that king's opposition, and on Alexander's death without issue in 1124, it was permanently reunited to the Scottish kingdom under David I.

Strathfieldsaye, a Hampshire estate, with a Queen Anne mansion, overlooking the Loddon, 7 miles NNE. of Basingstoke. Associated ere that with the name of Pitt, it was purchased by parliament in 1817 of Lord Rivers for £263,000, and presented to the Duke of Wellington. A conspicuous monument, crowned by a bronze statue of the Duke by Marochetti, was erected in 1866; and his charger, 'Copenhagen,' is buried in the grounds. See SILCHESTER, and the Rev. Charles H. Griffith's *History of Strathfieldsaye* (1892).

Strathmore (Gael., 'Great Valley'), the most extensive plain in Scotland, is a low-lying tract extending north-eastward across the country from Dumbartonshire to Stonehaven in Kincardineshire, and bounded on the north by the great mountain-rampart of the Highlands, and on the south by the Lennox, Ochil, and Sidlaw Hills. It is 100 miles long and from 5 to 10 miles broad; but Strathmore proper extends only from Perth to near Brechin (about 40 miles).

Strathnairn, LORD, commander-in-chief in India. Hugh Rose, son of Sir George Rose, was born 1803, and entered the army in 1820. He was military attaché to the Turkish army in the war with Mehemet Ali in 1840, was consul-general for Syria, and as secretary to Lord Stratford de Redcliffe was *chargé d'affaires* at Constantinople in 1853-54. He was commissioner at the French headquarters during the Crimean war, and, now K.C.B., was sent to India in 1857 to command the Central Indian army. In command of this force he virtually reconquered Central India; and, though his campaign was overshadowed by those of Sir Colin Campbell, it is generally admitted that the operations of Sir Hugh Rose were more brilliant and skilful than those of his chief. On the death of Lord Clyde Sir Hugh Rose became commander-in-chief in India: in 1865-70 he held the same post in Ireland. Raised to the peerage in 1866, and made field-marshal in 1877, he died 16th October 1885. See Sir O. T. Burne, *Clyde and Strathnairn* (1891).

Strathpeffer, a fashionable Scottish watering-place in the county of Ross and Cromarty, to the south of Ben Wyvis (3429 feet), and 5 miles W. of Dingwall by rail, 215 NNW. of Edinburgh. Its sulphur and chalybeate springs are highly efficacious in digestive and rheumatic disorders; and it has a pump-room with baths and three large hotels. See Dr Fortescue Fox's *Strathpeffer Spa* (1889).

Strathspey, a Scotch dance, allied to and danced alternately with the Reel (q.v.). The name is derived from the strath or valley of the Spey, where it seems to have originated; but it does not occur before the middle of the 18th century, and was at first applied indiscriminately to music now known as reels. It differs from the latter in being slower, and abounding in the jerky motion of dotted notes and semiquavers (when the latter precede the former it constitutes the *Scotch Snap*), while the reel is almost entirely in smooth, equal, gliding motion. Many of Burns's songs were written to the music of strathspeys.

Stratiotes. See WATER-SOLDIER.

Stratum (Lat., 'spread out'), equivalent in Geology to the term *bed* or *layer*, but implying that the beds or layers of rock have been spread out over the surface. Rocks so arranged are said to be stratified. The stratified rocks include all those that are of derivative origin, such as conglomerate, sandstone, shale, &c. Many igneous rocks, however, are also arranged in layers or beds, as in the case of the basalt plateaus of Antrim, the Inner Hebrides, the Faroe Islands, Iceland, &c. In these regions we encounter a great succession of sheets of basalt with interbedded layers of fragmental materials (tuff, &c.). Such consecutive series of igneous rocks are truly stratified. But when a geologist speaks of 'the stratified rocks' he is understood to refer more particularly to the derivative or aqueous rocks, the most important characteristic of which is their bedded or stratified arrangement. In a series of stratified rocks each individual layer of sandstone, shale, limestone, &c. is a stratum, which may or may not be homogeneous in structure. For while some beds consist of a series of thinner layers or laminæ, others show no such subordinate divisions. Thus, the particular variety of sandstone which is called *freestone* is not laminated, but of homogeneous structure, while a stratum of shale is composed of numerous thin laminæ. Such laminæ have a more or less close cohesion, which is sometimes so great that it is almost as easy to break the rock against as with the grain. Individual strata are more readily separated from overlying and underlying beds. The degree of cohesion between laminæ probably depends upon the rate at which sedimentation took place. If deposition was comparatively rapid the successive laminæ would tend to cohere more readily than would be the case where each individual layer had had time to become more or less solidified before the deposition of the succeeding laminæ. But in very many cases the cohesion of laminæ has been effected by subsequent pressure, and sometimes by infiltration of cementing material. The planes of stratification are always more strongly pronounced than those of lamination, and generally point to some lapse of time (longer or shorter as the case may be)—to a pause in the deposition of sedimentary matter. For further remarks, see GEOLOGY.

Straubing, an old town of Lower Bavaria, on the right bank of the Danube, 25 miles by rail SE. of Ratisbon, makes large quantities of bricks, lime, cement, and leather. Fraunhofer was a native. In a little chapel here there is a monument to Agnes Bernauer (q.v.). Pop. 12,804.

Strauss, DAVID FRIEDRICH, author of the famous *Leben Jesu*, was born on the 27th January 1808, at Ludwigsburg in Würtemberg. His education was begun in his native town, and completed in the theological seminaries of Blaubeuren and Tübingen. In 1830, his head filled with Hegel's philosophy and Schleiermacher's theology, he entered on the simple life of a country pastor; but already in the following year he was in Maulbronn acting as professor in the seminary, and went thence to Berlin for six months to continue his Hegelian studies, and hear the lectures of Schleiermacher. Returning to Tübingen in 1832, he became *repetent* in the theological seminary, and in the next years held also philosophical lectures in the university as a disciple of Hegel. Known as yet only to a narrow circle, he became all at once a man of mark by the publication, in 1835, of his *Life of Jesus critically treated* (2 vols. Tüb.; 4th ed. 1840; Eng. trans. by George Eliot, 1846). In this work he applied to the New Testament the method which had already worked havoc with the old legends of Greece and Rome, and which De Wette had to some extent applied to the Old Testament. Strauss attempted to prove the received gospel history to be a collection of myths gradually formed in the early Christian communities, and sought by an analytical dissection of each separate narrative to detect, where it existed, a nucleus of historical truth free from every trace of supernaturalism. The facts of the gospels were mere myths like those of the early Roman historians; no miracle, prophecy, or incarnation was left; the Christ of faith was a mere idea or group of ideas (see MIRACLES). The book made a real epoch in theological literature, and produced a violent excitement in and out of Germany, calling forth numberless replies from opponents, frightening many by its bold disregard of consequences back into the ranks of orthodoxy, and stirring up others to similar investigations. The first consequence to the author was his dismissal from his academical position in Tübingen, and transference to the Lyceum of Ludwigsburg. He resigned the new post, however, very soon in 1836, and retired into private life at Stuttgart, to have leisure to defend himself. In 1837 he published his *Streitschriften* against his opponents; and in 1838 *Zwei friedliche Blätter*, a more conciliatory exposition of his views. Early in 1839 he was called by the Board of Education in Zurich to be professor of Dogmatics and Church History in the university; but the step raised such a storm of opposition amongst the public that the proposition had to be dropped (he receiving a pension of 1000 francs), and even the cantonal government had to resign in the same year.

Thrown back on literary labour, Strauss, who had published during the year his *Charakteristiken und Kritiken*, sent forth shortly afterwards his second great work, *Die Christliche Glaubenslehre*, a review of Christian dogma 'in its historical development and its struggle with modern science' (1840–41). This formed a natural sequel to the purely critical investigation of the origins of Christianity in the first work. When Strauss, after a long period of silence, next appeared on the literary field it was no longer as a professed theologian. In 1847 he drew attention by a work entitled *Der Romantiker auf dem Throne der Casaren*, in which a parallel was drawn between the orthodox William IV. of Prussia and Julian the Apostate, as having both attempted to restore dead religions. His fellow-townsmen put him forward as a candidate for the German revolutionary parliament of 1848, but he was unable to stand against the clerical influence brought to bear upon the country-people of the district. His speeches on this occasion were published under the title of *Six Theologico-political Popular Addresses*, and his native place compensated the defeat by sending him as its representative to the Würtemberg Diet. From this position, however, when he unexpectedly displayed conservative leanings, and incurred a vote of censure from his constituents, he retired before the end of the year. In this period he also issued lives of the Swabian poet Schubart (1849) and of his college-friend Christian Märklin (1851); and a work on the old Swabian humanist Frischlin (1855). His third period of activity was opened in 1858 by a remarkable life of Ulrich von Hutten (Eng. trans. 1874), followed up by the publication of Hutten's *Dialogues* in 1860, a work on Reimarus (1862), and a series of brilliant lectures on Voltaire (1870). A new *Life of Jesus, composed for the German People*, appeared in 1864 (Eng. trans. 1865), in which the mythical theory was retained, but prefaced by a critical examination of the gospels (some historical value being allowed to Matthew), and an attempt made to reconstruct a positive life of Christ. *Der Christus des Glaubens* (1865) is a criticism of the lectures of Schleiermacher on the life of Jesus, and *Die Halben und die Ganzen* a brochure directed against Schenkel and Hengstenberg. In 1872 he published his last work, *Der alte und der neue Glaube*, in which he endeavours to prove that Christianity as a system of religious belief is practically dead, that there is no conscious or personal God, and that a new faith must be built up out of art and the scientific knowledge of nature. Strauss died at Ludwigsburg, 8th February 1874. In 1841 he had married the opera-singer, Agnese Schebest (1813-70), but some years after they separated. The literary, critical, and polemical powers of Strauss were unquestionably of a very high order; no more effective German prose than his has been written since Lessing.

A collected edition of Strauss's works was published in 12 vols. (including one of poems), edited by Zeller, in 1876-78. The *Life* by Zeller (1874) was translated the same year: and there are works by Hausrath (2 vols. 1876-78) and Schlottmann (1878).

Strauss, Johann, musical composer, best known for his waltz-music, was born in Vienna on 25th October 1825, the son of a Johann Strauss (1804–49) who also was renowned as a composer of dance-music. On his father's death he took the direction of his orchestra, and for many years travelled with it, at the same time producing melodious and catching waltzes (*Die schöne blaue Donau, Künstlerleben*, &c.), as also composed some very popular operettas—*Die Fledermaus* (1874), *La Tsigane* (1877), *Der Zigeunerbaron* (1885), &c.

Straw, Manufactures of. Apart from the importance of the straw of various cereal plants as a feeding and bedding material in agriculture, such substances also possess no inconsiderable value for packing merchandise, for thatching, for making mattresses, and for door-mats. Straw is also a paper-making material of some importance, and split, flattened, and coloured it is employed for making a mosaic-like veneer on fancy boxes. But it is in the form of plaits that straw finds its most outstanding industrial application, these being used to an enormous extent for making hats and bonnets and for small baskets, &c. Wheaten straw is the principal material used in the plait trade, the present great centres of which are Bedfordshire in England, Tuscany in Italy, and Canton in China. At first the plait was what is called *whole straw*; that is, the straw was cut into suitable lengths without knots, and merely pressed flat during the operation of plaiting; and so it continued until the reign of George I., when it was in great demand for ladies' hats, and some plait was made of split straw. Since that time split straw has been chiefly used. The instrument employed for splitting (fig. 1) consists of a number of little square steel blades radiating from a stem which terminates in the point *a*, and at the other end is bent and fixed into the handle *b*. The point *a*, being inserted into the hollow of the straw, is pressed forward, and cuts it into as many strips as there are blades in the cutting-tool. The English straw used in plaiting is obtained principally from the varieties of wheat known as the White Chittim and the Red Lammas, which succeed best on the light rich soils of Bedfordshire and the neighbouring counties. Only bright, clear, and perfect pipes can be employed, and to obtain the straw in good condition great care has to be exercised. The crop is not mowed, but pulled up, and the ears are cut off by the hand for thrashing. The straws are then cut into lengths, cleared of their outer sheath, and assorted into sizes in a kind of sieve apparatus like fig. 2. The apertures in each successive perforated top are increasingly wider, so that fine straws only pass through *a* by the shoot *b*, *c*, into the box *d* at the one end, and thicker pipes in each succeeding box. The plaits, made principally by women and children, vary greatly in pattern, quality, and cost. They are sold by the *score* of 20 yards, chiefly in Luton, where spacious plait halls have been provided for the accommodation of buyers and sellers. The finest and most costly plaits anywhere made —the Tuscan or Leghorn plaits—are made in Tuscan villages around Florence, and are not split. The straw there used—very fine in the pipe and bright in colour—is produced from a variety of wheat thickly sown and grown in a light thin soil. The crop is pulled and prepared as in the English trade, and the plaits are worked by all classes and ages of the rural populace. The finer qualities of

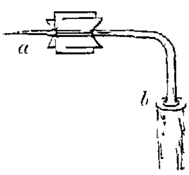


Fig. 1.

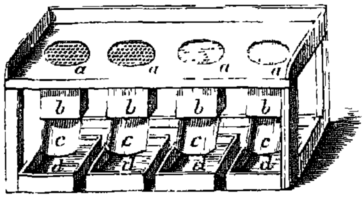

Fig. 2.

Tuscan plaits are worked with exceeding delicacy and elaboration, the task so straining the eyesight of the plaiters that they can give not more than two hours daily to the work.

Within recent years an enormous amount of straw-plait, of a common but useful quality, has been sent into the European market from China, the port of shipment being Canton. It can be sold in British markets at a price which excludes the possibility of competition by English plaiters, and the consequence is that the Bedfordshire trade in lower-class plaits is practically extinct. At the same time the supply of cheap Canton plaits has greatly benefited the hat and bonnet sewing industry of Luton and other Bedfordshire towns. In the year 1890 there were imported into the United Kingdom 8,558,542 lb. of straw-plaits, valued at £659,892, of which 7,306,100 lb., of a value of £476,210, came from Canton. Of this amount there was re-exported, principally to France, Germany, and the United States, 4,900,924 lb., valued at £328,177. Of hats and bonnets made from straw-plaits there were exported in the same year 653,104 dozen, valued at £371,262, the principal buyers being the Australian colonies.

Strawboard is a kind of Millboard (q.v.), or thick cardboard, made of straw after it has been boiled with lime or soda to soften it. The cheap kinds of strawboards are used for making common boxes of various kinds, and for protecting articles sent by post or railway. Good qualities of board suitable for binding books and other purposes are made of straw mixed with flax and jute waste from spinning-mills.

Strawberry. The Strawberry (Lat. *fragum*, whence the name of the genus Fragaria) belongs to the order Rosaceæ. Probably our name is descriptive of the habit of the fruiting plant, when the berries are strewn or strawn upon the ground—*humi nascentia fraga*—by their weight on the flexible footstalk. It is hard to believe, on the best authority, that the plant waited for its name till straw was laid beneath it. The calyx is ten-cleft, the petals five, and the seeds are imbedded in a fleshy receptacle, which is the delicious and fragrant fruit. The plant is a dwarf perennial, of stocky habit, and with handsome foliage, each leaf consisting of three leaflets, boldly toothed, and deeply ribbed; the stalk is generally long, and more or less hirsute, according to variety. The principal species are *F. vesca*, including the alpine and wood varieties; *F. elatior*, the hautbois; *F. viridis*, a rather scarce European plant; *F. virginiana*, a scarlet fruit; *F. grandiflora*, the pine strawberry; and *F. chilensis*, the Chilian. The hautbois, which is now believed to be a cultivated form of *F. vesca*, was probably our earliest garden strawberry, and the name is still used by the London street-vendors—'fine hoboy, ripe hoboy!'—for strawberries of all descriptions. The true hautbois is cultivated still for its rich and musky flavour, but larger and more fruitful kinds have generally superseded it. The magnificent fruit we now possess is chiefly the result of judicious crossings betwixt and among *virginiana*, *grandiflora*, and *chilensis*. The first great improvement appears to have been the introduction of the scarlet kind from Virginia in the beginning of the 17th century; and the old scarlet, though too acid for dessert, is still the very best for preserving. *F. grandiflora*, the old pine, has larger fruit of higher flavour, and darker and more substantial leaves. It is believed to have come from Carolina, and under that name was regarded for some years as the best and finest of strawberries. Even now there is none to surpass it in flavour, or equal it perhaps in texture; but larger and more productive kinds have ousted it from popularity. The garden strawberries of the present time have been obtained by repeated crossings, and it is impossible now to give their pedigree; but many of them show by hispid stalk and foliage a trace of Chilian lineage, for the Chilian is a very hairy plant and of vigorous growth, but tender. Our *British Queen*, perhaps the best known of all strawberries, is clearly of Chilian descent, and so are *Dr Hogg*, *Sir Charles Napier*, and others of fine character. Many favourite fruits show larger proportions of the *grandiflora* strain, such as *Keens' Seedling*, *Sir Joseph Paxton*, *Sir Harry*, and other dark varieties. Every year adds to our choice of sorts and helps to extend the season; and very early kinds are much in vogue, such as Laxton's *Noble* and *Captain*, which like all precocious fruit are of little other virtue. Besides the above, the following kinds are largely grown around London—*Vicomtesse Héricart* (or *Garibaldi*), *President*, *James Veitch*, *La Grosse Sucrée*, *Princess of Wales*, *Lucas*, *Elton Pine*, *Eleanor*, &c. Also from France, in the 'berry-season,' come tons and tons of coarser fruit which even uncrushed would be unknown to any good pomologist.

Planting strawberries for ourselves, we may rely upon a fine sweet crop if we show a little sense and take due care. First of all seek out the proper kinds for soil and climate, dividing (as may be fairly done, at least for practical purposes) all strawberries into three classes—(1) those of Chilian interbreed, which must have heavy soil even if poor, and weather not too barbarous, such as *British Queen* and congeners; (2) those of more glabrous and substantial leaf, being closely allied to the pine race, which care more for the quality than the substance of the soil, such as *Keens' Seedling*, &c.; (3) those of a strain so mixed that they must be studied individually, and sometimes flourish most upon a mixen. But however widely strawberries vary, almost all rejoice in having the earth well hardened around them, and the grower will marvel after all his labours to find the most vigorous and buxom of his plants established in the gravel-walk outside his higher culture. The strawberry is propagated in three manners—by seed, by side-shoots from the stool, and by runners. The last is the general course; and the runners or filiform stems (which issue generally at or soon after the fruiting season) should be pegged or fixed till the young plant is rooted. As early in the autumn as the young plants are strong enough, they are set out in the new beds in rows from 2 to 3 feet asunder, according to the vigour of the sort, and at intervals in the row of 15 or 18 inches. If the soil is light it should be rolled or heavily trodden before the planting time, and every young plant should have the earth rammed round it. Whenever a scarcity of runners or the weather has forbidden early planting it is better to wait till the spring than attempt to overtake the lateness lamely; and many kinds do best after wintering with their parents. The duration of a strawberry-bed depends very much upon the variety. Some of the small and early kinds are worn out by the second year of fruiting; while others of more robust habit do well for five or six years, or even more, if frequently cleared and kept in order and good heart. But none of these things has a hard and fast law. The forcing of strawberries is a special subject upon which we cannot enter. Brief as its season is of appearance in the market—from the first week of June to the last of July may be taken as the period of outdoor fruit in the neighbourhood of London—the strawberry has long won the affection of the people (at least for immediate despatch) more entirely than any or all other fruit whatsoever. At the height of the 'berry-time' it is amazing to see the fruit pouring into Covent Garden, from ship and from train, and by the English grower's van from all the nearer counties. The imported fruit is coarse, insipid, and generally in bad condition, but it serves to keep the prices low.

For further instructions, see works cited in our article upon *Gardening*; also Professor Decaisne's *Jardin Fruitier du Musée*; the *Illustrated Dictionary of Gardening*, by George Nicholson; and the *Strawberry and how to grow it*, by E. W. Harrison. For 'strawberry leaves,' see CORONET.

Strawberry Hill. See TWICKENHAM.

Streatham, a suburban parish in Surrey, 6½ miles SSW. of St Paul's. The Thrales's house, visited by Dr Johnson, is gone; but the church, though rebuilt in 1831, retains some interesting monuments. Pop. (1881) 25,553; (1891) 48,742. See F. Arnold's *History of Streatham* (1886).

Streator, a mining-town of Illinois, on the Vermilion River, and on five railways, 94 miles SW. of Chicago. Pop. (1880) 5157; (1890) 11,414.

Street, GEORGE EDMUND, architect, born at Woodford in Essex, 20th June 1824, was educated at Camberwell and Crediton, and studied for five years with Gilbert Scott. Starting in practice for himself in 1849, he designed many churches throughout the country, and restored more—the chief restoration being Christ Church Cathedral in Dublin. Cuddesdon College and Uppingham School are by him; but his most famous work is the new Law Courts in London, the subject of so much controversy (see Vol. VI. p. 703). Street became an A.R.A. in 1866, an R.A. in 1871, and P.R.I.B.A. in 1881. He died in London, 18th December 1881, and was buried in Westminster Abbey. He published *The Architecture of North Italy in the Middle Ages* (1855) and *Gothic Architecture in Spain* (1865). See Memoir by his son (1888).

Streltzi, or STRYELTSY. See RUSSIA, p. 46.

Strength of Materials is the heading under which it is usual to discuss the elastic or resisting properties of the materials used in engineering or building operations (see ELASTICITY, also STRAIN AND STRESS). When a structure is being designed the engineer must know first of all the amount and character of the stresses (loads, wind-pressures, &c.) that will act upon the structure. He must then decide as to the size and shape of the pieces that are to compose the structure, so that they may easily stand these stresses. For this purpose he must know beforehand what 'strength of material' is possessed by the steel, iron, or wood that is to be used.

When any substance is strained beyond a certain limit it will break, and the greatest stress which the substance can bear without being torn asunder is called its ultimate strength. The value of this for any given piece of material will depend upon the kind of strain to which it is being subjected. But whatever this strain be, whether extension, compression, flexure, or twisting, there are two, or at most three, distinct kinds of ultimate strength which practically fall to be considered. The one is the ultimate tension or pressure applied in one direction, usually longitudinally; and the other is the ultimate shearing stress, such as comes into play in simple torsion. In certain cases, such as in steel, wrought-iron, and ductile metals generally, the strength under tension and that under longitudinal pressure—in other words, the tenacity and the resistance to crushing—are practically the same. In other cases, however, of which cast-iron is the most interesting instance, the resistance to crushing is much greater than the tenacity. The ultimate strength under shearing is generally less than that under tension or compression. For example, the ultimate tensile strength of steel varies from 30 to 45 tons' weight per square inch of section, while the ultimate shearing strength varies from 22 to 35. Cast-iron, again, which has a tensile strength of 7½ tons' weight per square inch, has a strength under crushing of 45 and a shearing strength of 12.

It is out of the question to make a structure in which the pieces are strained up to their ultimate limits. For, even though the limit is not exceeded and the material not torn asunder, the excessive straining to near the limit will produce a permanent deterioration in strength. In other words, the 'working strength' is much smaller than the ultimate strength, being obtained from it by dividing by a number known as the 'factor of safety.' In the case of steel this factor is about 6; so that in no structure should a hard steel rod be subjected to a greater tension than 7½ tons' weight per square inch. Experience is the sole guide as to the value of this factor, which must be taken large enough to provide a margin of strength for all possible contingencies. Now, in the first place, the ultimate strength of a material that is to be used in a bridge or roof is somewhat uncertain. It is obtained by testing a sample. But no two samples of the same material have ever quite the same strength. Again, although theoretically a long column should have the same tensile strength as a short one of the same material and section, practically it is not so. There is greater chance of there being weak places in the longer column, and at the weakest place the material will begin to yield. Thus a greater factor of safety must be used in estimating the working strength of the longer rod. Then, in the second place, the character of the stress to which the material is to be subjected must be considered. If it is to be a fluctuating and not a steady stress the factor of safety must be increased, and similarly a wider margin of strength must be provided if the material is to be subjected to sudden shocks or impacts. For example, a bridge which is strong enough to allow a train to rest on it or to crawl over it, may be unable to support the train dashing at full speed. In fact, under a stress which fluctuates between wide limits the ultimate strength is diminished; hence if the ultimate strength has been measured by testing a sample under a steady stress, and if the substance is to be subjected to a sudden shock, the factor of safety is doubled.

A very important part of the subject is the consideration of the form best suited to resist certain strains. A glance at any fine modern structure, such as the Forth Bridge, will show how the form is varied, according as the member is in compression or in extension. Here the question of flexibility enters in. For although the strengths under extension and compression may be the same, yet if a rod is taken too thin and subjected to a longitudinal pressure, it will bend long before the true compression limits are reached. This bending or buckling must be prevented, and the only way of doing so is to increase the section. Thus hollow tubes resist buckling better than rods of the same length and mass. Herein also lies the great virtue of the I-shaped rod, which if laid horizontally and supported by its ends bends under its own weight very slightly as compared with the bending of a solid cylindrical rod of the same length and mass.

These and other important questions on the strength of materials are treated more or less fully in all the best text-books on engineering and applied mechanics. Barlow's *Strength of Materials* (6th ed. 1867) may be specially cited; also Fairbairn's *Mechanical Properties of Steel* (Brit. Assoc. Reports, 1867); Burr's *Elasticity and Resistance of the Materials of Engineering* (New York, 1883; new ed. 1889); and W. G. Kirkcaldy's *Strength and Properties of Materials* (New York, 1891).

Strepsiptera, peculiar insects referred by some to a special order, ranked by others among the Coleoptera. The females are blind and worm-like parasites, living inside various bees and wasps, but the adult males are free, with small twisted fore-wings and longitudinally-folded hind-wings. The larvæ, hatched within the adult bee or wasp, emerge and infest the grubs, but the parasitism of the males does not last long.

Stress. See STRAIN.

Stretton, HESBA, the pen-name of Sarah Smith, novelist and popular writer for the young, who was born at Wellington, Shropshire, where her father was a bookseller. Her first manuscript was accepted by Charles Dickens, and published in *Household Words*, to which she continued to contribute, as also to *All the Year Round*, until the death of its founder, whom she had found the most generous and sympathetic of editors. *Jessica's First Prayer*, published by the London Tract Society in 1867, and followed by a long series of semi-religious stories, interesting and pathetic, made her name a household word. She has published over forty juvenile stories and novels.

Strickland, AGNES, historian, was born at Reydon Hall near Southwold, Suffolk, August 19, 1806. She had begun verse-making ere her twelfth year, and had issued several volumes of poetry when the idea occurred to her of writing historical biographies of the queens of England. The suggestion came from some interesting biographies of female sovereigns written for a periodical by her sister Elizabeth (1794-1875). A start was made, and the first two volumes were published by Colburn and had a rapid sale; a misunderstanding between author and publisher was healed by Colburn's offer of £150 per volume until the work was completed (12 vols. 1840-48; new ed. 6 vols. 1864-65; abridged ed. 1867). In the production of this work she was assisted by her sister Elizabeth, though only the name of Agnes appears on the title-page. The work was dedicated to Queen Victoria, and as each volume appeared its picturesque style and anecdotical character made it a general favourite, though the *Quarterly Review* complained of a poverty of style and an equally pervading feebleness of thought, while the *Times* said it possessed 'the fascination of a romance united to the integrity of a history.' Miss Strickland, whose volumes give vivid pictures of the court and domestic life of the various periods, had strong opinions as to ecclesiastical government and royal prerogative, and was a partisan of the Stuarts. A civil list pension was conferred upon her in 1870. She died 8th July 1874. Agnes Strickland also wrote several novels and juvenile tales. Other works, written jointly with her sister Elizabeth, were *Lives of the Queens of Scotland* (1850-59), *Lives of the Seven Bishops* (1866), *Lives of the Tudor Princesses* (1868). The remaining works from the pen of Agnes were *Victoria from Birth to Bridal* (1840); *Letters of Mary Queen of Scots*, in whose innocence she believed (1842-43; new ed. 1864); *Bachelor Kings of England* (1861); *Lives of the Last Four Stuart Princesses* (1872). Her *Life of Mary Queen of Scots* (2 vols. 1873) was a redaction from the volumes in the *Queens of Scotland*. See Life, by her sister Jane (1887).

Stricture is a term employed in Surgery to denote an unnatural contraction, either congenital or acquired, of a mucous canal, such as the urethra, œsophagus, or intestine. When, however, the affected part is not mentioned, and a person is stated to suffer from stricture, it is always the urethral canal that is referred to. Contraction of this canal may be either permanent or transitory; the former is due to a thickening of the walls of the urethra in consequence of organic deposit, and is hence termed organic stricture; while the latter may be due either to local inflammation or congestion, or to abnormal muscular action: the first of these varieties may be termed inflammatory or congestive stricture, and the second spasmodic stricture. The last-named form seldom exists except as a complication of the other kinds of stricture. There are two principal causes of organic stricture—the first being inflammation of the canal, and the second injury by violence. Inflammation is by far the most common cause, and gonorrhœa is the common agent by which it is excited. Not unfrequently stimulating injections thrown into the urethra with the view of checking the gonorrhœal discharge excite an inflammatory action which gives rise to stricture. Fortunately it is only in exceptional cases that a stricture results from inflammation of the urethra, the inflammation, in the great majority of cases, terminating by resolution, and leaving the canal as healthy as before the attack. It is when the complaint assumes a chronic character that it most commonly lays the foundation of stricture. Stricture from the second cause arises from such causes as falling across spars, scaffolding, ladders, &c., or from some sharp object which punctures the perinæum—e.g. earthenware vessels which break under the sitter.

The earlier symptoms of stricture are a slight urethral discharge and pain in the canal behind the seat of the stricture at the time of micturition. The stream of urine does not pass in its ordinary form, but is flattened or twisted; and as the disease advances it becomes smaller, and ultimately the fluid may only be discharged in drops. The straining efforts to discharge the urine often induce Tenesmus (q.v.).

As the case advances the urine becomes alkaline and ropy, and deposits a precipitate when allowed to stand; and attacks of complete retention of urine occur with increasing frequency. But these symptoms are not in themselves sufficient to establish the presence of stricture. It is necessary to examine the urethral canal with a Catheter (q.v.) or Bougie (q.v.) to ascertain whether an organic obstruction exists, whether one or more strictures are present (as many as eight have been recorded, although four are rare, and one is the most common number), and their calibre. The treatment of organic stricture is too purely surgical to be discussed in these pages. It is sufficient to state that its object is twofold—viz. first, to restore the natural calibre of the canal so far as this can be safely effected; and secondly, to maintain this patency after it has been established.

Spasmodic stricture usually occurs as a complication of organic stricture or of inflammation of the mucous membrane, but may arise from an acrid condition of the urine, from the administration of cantharides, turpentine, &c., and from the voluntary retention of urine for too long a time. The treatment consists in the removal of the causes as far as possible and the hot bath. The inhalation of chloroform sometimes gives immediate relief; and several cases are recorded in which when the spasm occurred periodically it was cured by quinine. Inflammatory or congestive stricture commonly arises when a recent purulent discharge from the urethra has been checked by external cold or wet. The patient complains of heat, fullness, and soreness in the perinæum; the passage of the urine is extremely painful, the stream being small and ceasing before the bladder empties. The treatment is much the same as that for retention of Urine (q.v.).

Strigau, a town of Prussian Silesia, 25 miles SE. of Liegnitz, with granite-quarries, and manufacture of brushes, whips, sugar, &c. Pop. 11,784.

Strike, a term borrowed by geologists from the German *streichen*, 'to extend,' and adopted with the technical meaning it has in that language. It is applied to the direction of the outcrop of a stratum—the line which it makes when it appears at the surface of the earth. This line is always at right angles to the dip of the bed. The angle of dip and the direction of strike are determined by a clinometer and compass. A perfectly horizontal stratum can have neither dip nor strike.

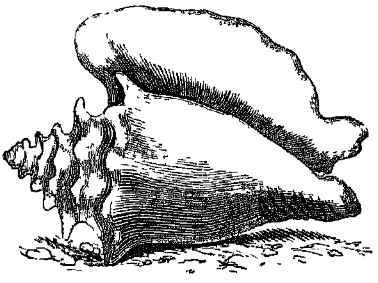
Strikes. See COMBINATION, TRADE-UNIONS.

Strindberg, AUGUST, the most prominent figure in modern Swedish literature, was born at Stockholm on 22d January 1849, and became successively 'schoolmaster, actor, physician, telegraph employé, civil servant, painter, preacher, private tutor, and librarian of the state,' all to get his experience at first hand. The first book of his that made its mark was *The Red Room* (1879), a bitter satire upon conventional (Swedish) society. This made its author enemies, and to their attacks he replied in another stinging satire, *The New Kingdom* (1882); but after its publication he had to go into voluntary banishment, and has ever since lived abroad. Two years later he published a collection of short stories (*Married Life*), in which he describes all sorts and conditions of nuptial alliances with cynical frankness. Accused of outraging Christianity in this book, Strindberg repaired to Stockholm, stood his trial, and after making an eloquent defence was acquitted. His next important work was a plea for the socialistic conception of society in *Utopias in the Real World* (1885). Two books descriptive of the life and manners of the inhabitants of the Stockholm skerries—*The People of Hemso* (1887) and *Life of the Skerry-Men* (1888)—are probably the best things he has written; though the play *The Father* (1887), one of four dramatic works in which he attacks the female sex, also deserves to rank high in Swedish literature. Two other novels, *Tschandala* (1889) and *On the Open Sea* (1890), turn upon the superiority of the aristocrat of brain over every other class of human being. Besides the books mentioned, Strindberg has produced—for he is a most prolific worker—a host of others, and in nearly all departments of literature. Unfortunately his artistic and poetic tendencies are in almost permanent conflict with his tendencies as thinker, reformer, and scientific observer; and this inherent dualism of his nature prevents his otherwise clever books from attaining the harmony, repose, and unity so essential to good literature. See Ola Hansson, *Das junge Skandinavien* (Dresden, 1891).

Stringhalt is a peculiar catching up of the horse's limbs, usually of one or both hind-limbs. It is most noticeable when the animal is first brought out of the stable, when he is excited, or made to turn suddenly round; it is a variety of chorea or St Vitus's dance. Although it does not interfere with usefulness, it is a serious eyesore, and quite incurable, and considerably depreciates the value of the horse.

Strom'boli, one of the Lipari Islands (q.v.), with a volcano almost constantly active.

Strombus, a genus of marine Gasteropods, typical of the family Strombidæ. Their shells, often called conch-shells, are well known, being often used as decorative objects and in the manufacture of cameos (see Vol. II. p. 675). Large numbers are exported from the West Indies and other tropical regions, and it is recorded that 300,000 fountain-shells (*Strombus gigas*) were brought to Liverpool in 1850. This species is the largest Gasteropod, the shell sometimes weighing 4 or 5 lb. The stromb-shell has a short conical spire and a much expanded outer lip, to which the popular name 'wing-shell' refers. The animals are allied to the cowries and whelks (Buccinum), and are very active, moving by short jumps. They feed on dead and decaying animal matter.



Fountain-shell (*Strombus gigas*).

Stromness, a seaport in Pomona, Orkney, on a beautiful bay, 15 miles W. by S. of Kirkwall. Gow, Scott's 'Pirate,' was born here. Pop. 1633.

Strongbow, the surname of Richard de Clare, Earl of Pembroke, who went to Ireland to push his fortune in 1170 by permission of Henry II. (q.v.). He married the daughter of Dermot, king of Leinster, became governor of Ireland in 1173, and died at Dublin in 1176.

Stronsay, one of the Orkney Islands (q.v.).

Strontium (sym. Sr, dyad, atomic weight, 87·5—O = 16—sp. gr. 2·542) is a ductile and malleable metal, somewhat harder than lead, and of a pale yellow colour. When heated in the air it burns with a crimson flame, and becomes converted into its oxide, strontia, SrO. It is unaffected by the action of dry air, but it decomposes water at an ordinary temperature, hydrogen being explosively developed; and it burns in chlorine gas, and in the vapour of iodine, bromine, and sulphur. It dissolves in dilute nitric acid, but the strong acid has scarcely any effect on it. This metal does not occur in the native state, but exists as a carbonate in the mineral *Strontianite* (so called from its being first found in 1790 near Strontian, a village of Ardnamurchan parish, Argyllshire, 24 miles SW. of Fort-William), and as a sulphate in the mineral known as *Celestine*. It is obtained by the voltaic decomposition of the chloride of strontium. This metal bears to barium the same close relation that sodium bears to potassium; and the compounds of strontium resemble those of barium not only in their composition but in their properties. The oxide of strontium, commonly known as Strontia, is obtained in the same way as the corresponding oxide of barium, which it resembles in almost all respects, except that it is inert when taken into the system, while baryta is poisonous. When a small quantity of water is poured upon it it slakes, giving out heat.

The salts of strontia resemble those of baryta in their general characters, and in their being precipitated from their solutions by sulphuric acid and the soluble sulphates; but they differ from them in not being thrown down by silico-fluoric acid or hyposulphite of soda, and in their communicating to the flame of the spirit-lamp and to burning substances generally a brilliant purple-red colour. The salts of strontia occur only in the mineral kingdom, and are never found as normal ingredients of organic bodies. *Carbonate of Strontia*, $SrCO_3$, occurs native both in a massive and crystalline form, and may be obtained artificially as a white powder by precipitating a soluble salt of strontia with carbonate of soda. *Sulphate of Strontia* occurs native in *Celestine*, a mineral which is found in beautiful rhombic prisms in Sicily. *Nitrate of Strontia*, $Sr(NO_3)_2$, separates from a hot concentrated solution in large colourless transparent anhydrous octahedral crystals, which dissolve freely in water. By the addition of nitric acid it is precipitated from its aqueous solution. This salt is insoluble in alcohol, but when finely powdered and mixed with it it communicates to the alcoholic flame a beautiful red or crimson colour. In consequence of this property it is employed by the makers of fireworks, especially for Bengal lights (see PYROTECHNY); but the mixture made for this purpose is highly dangerous, and has caused bad accidents by igniting spontaneously. The most important of the haloid salts of strontia is the *Chloride*, $SrCl_2$, which may be obtained in crystals containing six equivalents of water. The water is expelled at a moderate heat, leaving the chloride anhydrous. The chloride is the only salt from which the metal has hitherto been obtained.

Strontia was discovered as an independent substance almost simultaneously by Hope and Klaproth in 1793. In 1807 Davy obtained barium and strontium from their oxides, but not in a pure state; and it was not till 1855 that Bunsen and Matthiessen succeeded in procuring perfectly pure specimens of the metal.

Strophanthus, a genus of plants belonging to the natural order Apocynaceæ, and natives of tropical Africa and Asia. The flowers are in terminal heads; the corolla is funnel-shaped, with its limb divided into five long cord-like segments (hence the name, Gr. *strophos*, 'a twisted cord,' *anthos*, 'a flower'); the style is thread-like, surmounted by a cylindrical stigma; and the fruit is a double follicle. Each follicle contains a large number of seeds having beautiful comose awns. There are several species, but the best known is the *S. hispidus*, var. *Kombé*, the seeds of which are now largely used in medicine. This species is widely distributed in tropical Africa, and climbs up the highest trees, hanging from one to the other in festoons. It has follicles 8 to 12 inches long, containing from about 100 to 200 seeds, each of which weighs about half a grain. An extract of the seeds is used as an arrow-poison (Kombé or inee) in districts widely apart, as at Kombé, in the Manganja country, in the Zambesi district, in the Somali country, in the Gaboon district, in Guinea, and in Senegambia. Dr Livingstone described it as used for killing animals only. The wounded animal is followed until the poison begins to take effect, it is then watched until it drops, the portion of meat round the wound is cut away and all the rest eaten.

In the British Pharmacopœia Strophanthus is defined as the mature ripe seeds of *S. hispidus*, var. *Kombé*, freed from the awns. Each seed is about ⅜ inch long, ⅙ inch broad, oval in shape, and flattened at the sides. The seed-coat is of a fawn colour, and covered with silky hairs. The kernel is white and oily, with a very bitter taste. The seeds contain an active principle, *strophanthin*, which is extremely poisonous, the medicinal dose of it being $\frac{1}{120}$ to $\frac{1}{80}$ grain. The drug is usually administered in the form of the officinal tincture of strophanthus made from the seed, of which the dose is 2 to 10 minims. Its action and uses are very similar to those of Digitalis (q.v.).

Stroud, a manufacturing and market town of Gloucestershire, 10 miles SSE. of Gloucester, on an eminence in a valley sheltered by the Cotswolds, where the Frome and Slade rivulets unite to form the Stroud Water or Frome. The water of this stream being peculiarly adapted for use in dyeing scarlet and other grain colours, cloth-factories and dyeworks have been built along its banks for 20 miles; and Stroud itself is the centre of the woollen manufactures of Gloucestershire, and contains a number of cloth-mills. The parish church, St Lawrence, was rebuilt, with exception of the tower and spire, in 1866-68; the town-hall, incorporating an Elizabethan façade, in 1865; and there are also the Subscription-rooms (1830), the Lansdown Hall (1879), a hospital (1876), &c. From 1832 to 1885 Stroud, with twelve other parishes, formed a parliamentary borough, returning two members. Pop. (1881) 9535; (1891) 9818.

Struensee, JOHANN FRIEDRICH, COUNT, was the son of a German pastor of Halle, where he was born 5th August 1737. He studied medicine, and was appointed (1759) town physician in Altona. But in 1768 he accepted the post of private physician to Christian VII. of Denmark (1749-1808). He soon gained the complete confidence not only of the weak young king, but also of his consort, Caroline (1751-75), sister of George III. of England, who had a most unhappy lot as the wife of Christian. Struensee and the queen speedily possessed themselves of all power in the kingdom, dismissing the former ministers, forcing the king to abstain from all interference with government, and endeavouring to free Denmark from Russian influence, and to find a natural ally in Sweden. The changes which Struensee undertook in internal affairs were directed to the advancement of the prosperity of the country, of civil liberty, and enlightenment. He put the finances in order, reduced the expenditure, loosened the fetters in which industry and trade had been bound, encouraged education, mitigated the penal laws, and brought order into the administration. An act passed in 1771 to a certain extent abolished serfdom. But by all these measures he offended and outraged the nobility and the clergy, and by the haste and want of statesmanlike tact and skill with which they were carried out he appeared to the peasantry as little different from a despotic tyrant. The disaffected nobles and deposed ministers found a supporter in Christian's step-mother, and procured from the king an order for the arrest (16th January 1772) of the queen and Struensee. From both a confession of criminal intimacy was extorted; the queen was confined in the prison-fortress of Kronborg, while Struensee was cast in chains into the citadel of Copenhagen. Various charges of abusing the royal authority, attempting to force the king to abdicate, besides that of adultery with the queen, were laid to the charge of the favourite, and on 28th April 1772 he was beheaded. Queen Caroline's marriage was dissolved, and, parted from her only little daughter, she was conveyed by a British frigate to Hanover, where she died at Celle in 1775.

See a very full account in the *Memoirs and Correspondence* (1849) of Sir Robert Murray Keith, who was British envoy to Copenhagen at the time, and saved the queen from the fury of the populace; Wraxall's *Life and Times of Queen Caroline Matilda* (3 vols. 1864); and the article by Professor Ward on Caroline Matilda in the *Dict. Nat. Biog.* (vol. ix. 1887).

Struma, a term equivalent to Scrofula (q.v.).

Strutt, JOSEPH, antiquary, was born at Springfield in Essex, October 27, 1742, at fourteen was apprenticed to an engraver, studied art in the Royal Academy, and early gave himself to exceptionally laborious studies at the British Museum. He died in London, October 16, 1802, after a life spent, spite of poverty and sickness, in devotion to learning. His most important book was his last, the invaluable *Sports and Pastimes of the People of England* (1801). His first book was *The Regal and Ecclesiastical Antiquities of England* (1773); among its successors were his *Horda-Angel-Cynnan*, or a complete view of the Manners, Customs, Arms, Habits, &c. of the Inhabitants of England (1774–75–76); *Chronicle of England*, down to the Norman Conquest (1777–78); a *Biographical Dictionary of Engravers* (1785–86); and *Complete View of the Dress and Habits of the People of England* (1796–99).

Struve, FRIEDRICH GEORG WILHELM, German astronomer, was born at Altona, April 15, 1793, educated at the university of Dorpat (Russia), and appointed to a post in the observatory of that place in 1813. He became director of the Dorpat Observatory in 1817, and in 1839 was placed at the head of the new observatory of Pulkova near St Petersburg. He retired in 1861, and died at St Petersburg on 23d November 1864. He directed his attention principally to the observation of double stars, and collected materials for three important works (1827, 1837, 1852) dealing with this branch of astronomy. He also carried out a number of important geodetic operations, such as the triangulation of Livonia (in 1816–19) and the measurement of an arc of the meridian in the Baltic Provinces (in 1822–27), which was subsequently (1828–56) extended by him, in conjunction with Hansteen (q.v.) and Selander, to the North Cape, and by General Tenner southwards to Ismail in Turkey. For this last gigantic undertaking, see Struve's *Arc du Méridien entre le Danube et la Mer Glaciale* (St Petersburg, 1857–60).—His son, OTTO WILHELM STRUVE, also an astronomer, was born at Dorpat, May 7, 1819, was educated under his father's direction, became his chief assistant at Pulkova, and the director of the same observatory after his retirement. He has made numerous astronomical discoveries, among which are more than 500 new double stars and (1847) a satellite of Uranus, and has written numerous papers, the most noticeable of which set forth his researches on the rings of Saturn and on the periodic motions of double stars.

Stry, or STRYI, a town of Austrian Galicia, on a tributary of the Dniester, 45 miles by rail S. of Lemberg, with sawmills and tanneries. Pop. 12,625, nearly one-half Jews. The town was almost wholly burned down in April 1886.

Strychnine, a poisonous drug, is named from a genus of tropical trees and shrubs of the order Loganiaceæ. The most notable species is the *Strychnos Nux Vomica*, so called from the name Nux Vomica given to its seeds, the source of strychnine. The tree and its seeds are described at NUX VOMICA. From various species of Strychnos are obtained the Clearing Nut (q.v.), the Curari (q.v.) poison, and Ignatius' Beans (q.v.); while one kind of Upas poison (*Upas tieute*) is made from a species of Strychnos.

Strychnine, $C_{21}H_{22}N_2O_2$, is an alkaloid occurring in crystals, has an intensely bitter taste, is colourless and inodorous, scarcely soluble in water, but easily soluble in boiling rectified spirit, in ether, and in chloroform. Pure sulphuric acid forms with it a colourless solution, which, on the addition of bichromate of potash, acquires an intensely violet hue, speedily passing through red to yellow. In nitric acid it ought, if pure, to form a colourless solution; if the solution is reddish it is a sign that brucine is also present. Strychnine combines with numerous acids, and forms well-marked salts, which give the same reactions as the base itself. Nux vomica seeds contain about ·2 to ·5 per cent. of it.—*Brucine* is the subject of a separate article.

Strychnine and brucine occur not only in nux vomica, but in the seeds of *Strychnos amara* (St Ignatius' beans) and in the seeds and other parts of several plants of the genus Strychnos. Nux vomica and its alkaloids are very poisonous to all kinds of animals. It is believed, however, that the bird called *Buceros rhinoceros* eats the nuts with impunity; and a peculiar kind of Acarus lives and thrives in the extract of the nuts. In small doses ($\frac{1}{30}$th to $\frac{1}{12}$th grain) it is largely used in medicine as a stimulant, as a tonic, and as a bitter. The officinal preparations are made from nux vomica and from strychnine. In *poisoning with strychnine* the symptoms depend on excessive stimulation of the spinal cord, and when fully developed consist in rigid tetanic convulsions. These are preceded by muscular twitchings, cramps, and jerking movements. Each spasm lasts one or two minutes, and is followed by a short remission, during which the person lies *completely exhausted, but able to converse and swallow.* The slightest touch, a noise, or even a draught of air will bring on a spasm. The mind *generally remains quite clear.* Death takes place within two hours from exhaustion, or from suffocation produced by the impossibility of breathing during the spasms. Death may occur in a few minutes, however; a quarter of a grain is the smallest fatal dose of strychnine recorded, but patients have survived much larger amounts.

The treatment, after emptying the stomach, consists in keeping the patient as quiet as possible, and in administering substances which will depress the spinal cord, and thereby allay the tetanic spasms. Chloral hydrate and bromide of potassium by the mouth or rectum have been found useful in this respect. But putting the patient deeply under the influence of chloroform is probably the most efficacious mode of treatment.

Strype, JOHN, a voluminous ecclesiastical historian, was born in London, November 1, 1643, the same year as Burnet. He was educated at St Paul's School, whence he passed first to Jesus College, then to Catharine Hall, Cambridge. He was presented in 1669 to the perpetual curacy of Theydon-Bois in Essex, which he resigned a little later to become minister of Low Leyton in the same county. Later he received the sinecure of Tarring in Sussex and the lectureship of Hackney, which he resigned in 1724. He died at Hackney, December 11, 1737, aged ninety-four. His works fill thirteen folio volumes (27 vols., Clar. Press ed., 1821–43). The most important are *Memorials of Archbishop Cranmer* (1694); *Life of Sir Thomas Smith, Secretary of State to Edward VI. and Elizabeth* (1698); Lives of *Bishop Aylmer* (1701), *Sir John Cheke* (1705), *Archbishop Grindal* (1710), *Archbishop Parker* (1711), and *Archbishop Whitgift* (1718); *Annals of the Reformation* (vol. i. 1709, vol. ii. 1723, vol. iii. 1728, and vol. iv. 1731); *Ecclesiastical Memorials*, relating to religion and the Church of England under Henry VIII., Edward VI., and Queen Mary (3 vols. 1721). This last is his best work, forming, with Burnet's more readable *History of the Reformation*, a consecutive and full account of the reformed Anglican Church. Strype also published an enlarged edition of Stow's *Survey of London* (2 vols. 1720), with several sermons and pamphlets. As a writer he is heavy and unskilful in arrangement, but laborious and honest, and his transcriptions of the ancient papers he published may be trusted. A simple-minded but sincere man, he has left to posterity a series of works of the very greatest value despite their prolixity, irrelevant details, and tiresome repetitions.

Stuart. See STEWART.

Stuart, GILBERT CHARLES, American painter, was born at Narragansett, Rhode Island, in 1756. In his boyhood he went to Edinburgh with a Scotch painter named Alexander, with whom he studied his art; but his master dying, he worked his passage home, and began to paint portraits at Newport. In 1775 he made his way to London, where he led for two years a Bohemian life; but his talent was recognised by his countryman, Benjamin West, who took him into his family, and soon he became a fashionable portrait-painter. In 1792, in the fullness of his powers and fame, he returned to America, and painted portraits of Washington, Jefferson, Madison, John Adams, and many of the distinguished men of the period, and was at work on a portrait of John Quincy Adams (afterwards finished by Sully) when he died at Boston, 27th July 1828. See a Life by G. C. Mason (New York, 1879).

Stuart, JOHN, LL.D. (1813–77), a Scottish antiquary, for twenty-four years attached to the Register House. His principal works were *The Sculptured Stones of Scotland* (2 vols. 1856–67) and *The Book of Deer* (see DEER). He contributed largely to the *Proceedings* of the Scottish Society of Antiquaries, of which he was secretary.

Stuart, MOSES, American divine and author, was born at Wilton, Connecticut, in 1780, and educated at Yale, where he remained for some time as a tutor. He began the study of law, but abandoned it for theology, was ordained as pastor of a Congregational church at New Haven in 1806, and in 1810 was appointed professor of Sacred Literature at Andover, a position he filled till 1848. During this period he published Hebrew grammars without (1813) and with points (1821), a translation of Winer's Greek grammar, commentaries on Hebrews, Romans, the Apocalypse, Daniel, Ecclesiastes, and Proverbs; *Hebrew Chrestomathy* (1829–30); Essays on *Future Punishment* (1830) and on *Christian Baptism* (1833); *Hints on the Interpretation of Prophecy* (1842); *Conscience and the Constitution* (1850); and numerous translations and letters. He died January 4, 1852.

Stubbes, JOHN, was born about 1541, had his education at Corpus Christi College, Cambridge, and Lincoln's Inn, and died about 1600. He wrote an answer to Cardinal Allen's *Defence of the English Catholics*, but is known by *The Discoverie of a Gaping Gulf, wherein England is like to be swallowed up by another French Marriage* (1579), against the marriage of Elizabeth with the Duke of Anjou. For his patriotism both himself and Page his printer had their right hands struck off. —PHILIP STUBBES, his near kinsman, was author of the *Anatomie of Abuses* (1583): conteyning a Discoverie or Briefe Summarie of such Notable Vices and Imperfections as now raigne in many Christian countreyes of the World: but especialie in a very famous Ilande called Ailgna: Together with most fearful Examples of God's Judgementes executed upon the wicked for the same as well in Ailgna of late, as in other places elsewhere. Wood tells us that he was 'a most rigid Calvinist, a bitter enemy to popery, and a great corrector of the vices and abuses of his time; and though not in sacred orders, yet the books he wrote related to divinity and morality.' A second part of his book appeared the same year (1583). In form it is a dialogue between Philoponus and Spudeus; the substance is a vehement denunciation of the luxury of the times, valuable in the highest degree to us for the light it throws on the dress and habits of the age of Shakespeare. Stubbes is, himself, really a bigoted and splenetic old fool, and he inveighs with curious passion against all extravagances of dress—'the great ruffs, puffed out doublets of the men; the curling, frizzling, and crisping of the hair of the women; their great ruffs and neckerchers of holland, lawne, camerick, and such cloth, lest they should fall down, smeared and smirched in the devil's liquor—starch.' In his blindness he saps the very foundations of morality by pouring out his wrath alike on the mere extravagances of fashion and upon breaches of the weightier matters of the law. The work was reprinted by W. B. D. D. Turnbull in 1836, and by F. J. Furnivall in the New Shakespeare Society's issues (1879, 1882).

Stubbs, WILLIAM, historian, was born at Knaresborough, 21st June 1825, and was educated at Ripon grammar-school and Christ Church, Oxford, graduating with a classical first-class in 1848. He was at once elected to a fellowship at Trinity College, took orders, and became vicar of Navestock, Essex, in 1850. He acted as diocesan inspector of schools from 1860 till 1866, when he was appointed regius professor of Modern History at Oxford, with the year following a fellowship at Oriel. He was appointed librarian to Archbishop Longley at Lambeth in 1862, a curator of the Bodleian in 1868, rector of Cholderton, Wiltshire, in 1875, and canon residentiary of St Paul's in 1879. He was consecrated Bishop of Chester in 1884, and translated to the see of Oxford in 1889. Bishop Stubbs's historical work is marked by vast learning and rare impartiality and sagacity. The reader may follow him with complete confidence, and the only thing left to desiderate is a more supple and expressive style. Of his many works the chief are *Registrum Sacrum Anglicanum:* an attempt to exhibit the course of Episcopal succession in England (1858); Mosheim's *Institutes of Ecclesiastical History*, thoroughly revised and brought down to the present time (3 vols. 1863); *Select Charters and other Illustrations of English Constitutional History*, from the earliest period to the reign of Edward I. (1870); the altogether invaluable *Constitutional History of England in its Origin and Development* down to the accession of the House of Tudor (3 vols. 1874–78); *The Early Plantagenets* in 'Epochs of Modern History' (1876); and *Seventeen Lectures on the Study of Mediæval and Modern History* (1886).

Besides these he has edited, in the Records publications, of the reign of Richard I., the *Itinerarium* and *Epistolæ Cantuarenses* (2 vols. 1864–65); Benedict of Peterborough's *Gesta* of Henry II. and Richard I. (2 vols. 1867); Roger de Hovedon's *Chronicle* (4 vols. 1868–71); *The Historical Collections of Walter of Coventry* (2 vols. 1872–73); *Memorials of Saint Dunstan* (1874); the *Historical Works of Master Ralph de Diceto* (2 vols. 1876); the *Historical Works* of Gervase of Canterbury, covering the reigns of Stephen, Henry II., and Richard I. (2 vols. 1879–80); *Chronicles of the Reigns of Edward I. and Edward II.* (2 vols. 1882–83); The Five Books of William of Malmesbury *De Regum Gestis Anglorum*, and the Three Books of his *Historiæ Novellæ* (2 vols. 1887–89). Bishop Stubbs received honorary degrees from Cambridge, Edinburgh, and Dublin, and is a corresponding member of the Institute of France, and other learned societies of Massachusetts, Denmark, Göttingen, Kieff, &c. He began with the Rev. A. W. Haddan the publication of a collection of *Councils and Ecclesiastical Documents relating to Great Britain and Ireland*, based on the *Concilia* of Spelman and Wilkins (3 vols. 1869–78).

Stucco, a term applied to work in plaster of Paris (sometimes mixed with other ingredients) used for coating walls or making casts of figures. See GYPSUM, PLASTERING, CAST.

Stud-book, a book containing the pedigrees of famous animals, especially horses. That for race-horses, edited by the officials of the Jockey Club, dates from 1808. There are stud-books for Clydesdale horses, cattle, &c., and even separate ones for collies, fox-terriers, St Bernard dogs, &c.

Stuffing. See TAXIDERMY.

Stuhlweissenburg (Hung. *Székes Fehérvár*, Lat. *Alba Regia*), a royal free town of Hungary, and seat of a bishop, lies in a swampy plain, 39 miles SW. of Budapest. Here from 1027 to 1527 the kings of Hungary were crowned and buried. The town was in the possession of the Turks almost continuously from 1543 to 1688. It is now greatly decayed, but has celebrated horse-fairs. Pop. 25,612.

Stukeley, William, antiquary, was born at Holbeach, Lincolnshire, 7th November 1687, and from the grammar-school there passed in 1703 to Corpus Christi College, Cambridge. Having taken his M.B. (1709) and studied at St Thomas' Hospital, he practised successively at Boston, London, and Grantham, meanwhile proceeding M.D., and being admitted an F.R.C.P. But in 1729 he took orders, and, after holding two Lincolnshire livings, in 1747 was presented to the rectory of St George the Martyr in Queen Square, London, where he died, 3d March 1765. His twenty works, published between 1720 and 1726, and dealing with Stonehenge, Avebury, and antiquities generally, enshrine a good deal that is curious, and have preserved much that might else have perished, but they are marred by a credulity and fancifulness which won for him the title of the 'Arch-Druid.' See his *Family Memoirs*, edited for the Surtees Society (3 vols. 1884-87).

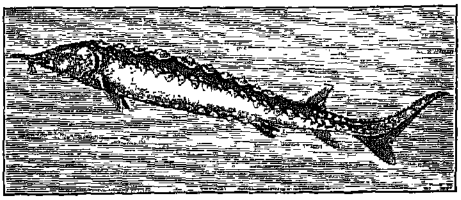
Stundists. See Russia, p. 36.

Sturdy, or the Gid, affects young sheep, and sometimes young cattle, and is due to the presence within the brain of a Hydatid or bladder-worm, the *Cœnurus cerebralis*, which is the embryonic or cystic stage of the tapeworm—the *Tænia cœnurus*, mostly found in dogs. The bladder or cyst, sometimes the size of a hen's egg, consists of an enveloping membrane, formed by the membranes of the brain, and contains a watery fluid. Upon its surface the membrane is covered with white dots in groups, and if these are closely examined with a slightly magnifying glass they will be found to be the heads of the Tænia in various stages of development. This hydatid, when given to dogs, is known to produce tapeworms, and conversely itself originates from the ova of the tapeworm ejected on the pastures with the fæces of dogs. In the state of ova, or in some of its earlier minuter transitional forms, the hydatid embryo is picked up along with the grass, passes into the blood, and is thence laid down in the soft loose textures of the brain. It is but rarely seen where no dogs are kept, or perhaps where no foxes abound, and amongst sheep from six to twenty months old. The animal cannot properly seek its food, loses condition, staggers when moved, turns stupidly round almost in one spot, and usually towards the side on which the hydatid lies. The parasite and its sac may generally be removed by placing the sheep, with its feet tied, on a table or bench, searching for the softened portion of the skull, which generally overlies the hydatid, laying back a flap of skin, and introducing the trochar and canula, and, when the sac is deep-seated, cautiously withdrawing it with the help of a small syringe. Protected by a leather cap and simple water-dressings, the wound may heal and the sheep recover.

Sture, a noble family of Sweden, which furnished three successive regents to that country during the period (1470 to 1520) it was nominally united with Denmark. The first of these was Sten Sture the Elder (died 1503), an enlightened and far-seeing statesman, who, relying upon the peasantry, combated the pretensions of both clergy and nobility, successfully withstood the Danes, and encouraged learning by founding the university of Upsala, introducing printing into Sweden, and inviting thither learned men. He was succeeded by his nephew, Svante Nilsson Sture (died 1512), who also fought bravely against the Danes; and the third regent of the family was Sten Sture the Younger (died 1520), who was mortally wounded in battle against the Danes.

Sturgeon (*Acipenser*), a genus of Ganoid fishes of the family Acipenseridæ, order Chondrostei. The Chondrostei are Ganoids without ganoid scales, the skin being either naked or with bony plates, as in the sturgeon. The skull is cartilaginous, but covered externally with bony plates belonging to the skin. The tail is asymmetrical or heterocercal, and the gelatinous notochord persists in the centre of the vertebral column throughout life. Spiracles like those of sharks and skates are present in some genera. The distinguishing features of Acipenser are these: the body is long and narrow, and the skin is provided with five longitudinal rows of bony shields, each bearing a projecting keel. One row of these bony plates is along each side of the body, one along the back, and one on each side of the ventral surface. The skin between these rows of plates is naked, but contains minute scales which give it a rough surface. The head projects into a flat, pointed snout, provided with fleshy tentacles or barbels; and on the under surface of this snout, some distance behind its extremity, is the mouth, which is without teeth, and capable of protrusion. The gill-opening is wide. There are two pairs of fins, the pelvic being situated a long way back, close to the anus. There are two median fins, one dorsal and one ventral, both near the tail. The fin-rays are jointed and flexible. Spiracles are present behind the eyes. The air-bladder communicates with the gullet. There are many species of sturgeon, all confined to the northern hemisphere. They live in the sea and great lakes, and ascend the great rivers. All are of considerable size, and supply valuable commodities, for which they are regularly captured on a large scale. These commodities are their flesh, which is palatable and wholesome, their roe (Caviare, *q.v.*), and their air-bladders, from which isinglass is made. The eggs are small and numerous, like those of bony fishes; there is no copulation, the ova being laid and fertilised on the bottom of the upper parts of rivers, like those of the salmon. The food of sturgeons consists of worms, crustacea, and molluscs, which they seek by routing in the sea-bottom with their snouts.

The Common Sturgeon (*A. sturio*) is the only species which occurs in British seas and rivers.



Sturgeon (*Acipenser sturio*).

The specific characters distinguishing the species are minute, consisting in the number of the bony scales, position of the fins, length of the snout, &c. *A. sturio* is sometimes taken by trawlers at sea, more often in salmon stake-nets, and in estuaries, especially in the Severn. It enters the rivers in the early part of the year for the purpose of breeding. When adult it is from 6 to 10 feet long. It occurs in the Mediterranean, western and northern Europe, and on the Atlantic coast of America, but is absent from the Black Sea and Danube, and from the Caspian Sea. In England, as early as Edward II.'s reign, the sturgeon was a royal fish, belonging to the king when captured. The Sterlet (*A. ruthenus*) is a much smaller species, which is common in the Black and Caspian Seas, and ascends the Danube as far as Vienna. It is one of the principal objects of the sturgeon-fishery on the Volga. *A. huso* is the largest species, reaching 25 feet in length, and also belongs to the Black and Caspian Seas. *A. stellatus* is another species of these seas; it reaches 5 feet in length. Other species occur on the Atlantic and Arctic coasts of North America, in the great lakes of the St Lawrence system, in California, and on the west coasts of the North Pacific, in China, and eastern Siberia. *A. brevirostris* belongs to the southern Atlantic coasts of the United States. The species of the great lakes of the St Lawrence is *A. rubicundus.* The species of California and the Pacific coast is *A. transmontanus.*

The most important sturgeon-fishery in Europe is that of the Volga and the Caspian Sea. The flesh of the fish is salted, and caviare and isinglass made on a large scale from the roes and air-bladder. In America sturgeon flesh is eaten fresh, and caviare is made both in Georgia and in San Francisco; but there is no great fishery in any particular district, and the manufacture of Isinglass (q.v.) does not receive much attention.

Sturlason. See SNORRI.

Sturm, JOHANNES, well known as an educational reformer, was born at Sleiden, in the duchy of Luxemburg, 1st October 1507. In his fifteenth year he was sent to Liége, where he attended a school of the Brothers of the Common Life—a school so admirably organised that in his own subsequent reform of the schools at Strasburg Sturm largely followed its model. Three years later Sturm continued his studies at Louvain, then the most enlightened centre of the higher studies north of the Alps, where shortly before there had been founded a college for the teaching of Latin, Greek, and Hebrew. Besides his zeal as an educational reformer Sturm all through life had the ambition to write a Latin style framed on the best models of antiquity. It was at this time, therefore, that he began the assiduous study of Cicero, whom to the end he never ceased to read with unabated zeal. He remained some five years in Louvain.

In 1529 he went to Paris, and at first gave himself to medicine, with a view to securing a settled competence. But his natural instinct again declared itself, and he returned to the study of Cicero, on whom he gave courses of lectures in the Collége Royal. Besides lecturing on Cicero he also taught dialectics, and had for one of his students Petrus Ramus (q.v.). As a sympathiser with the new teaching in religion, identified as yet only with the name of Luther, it was at some risk that Sturm made his home in Paris. Accordingly, when a request was made to him (1536) by the authorities of Strasburg to come to their assistance in reorganising the education of their town, Sturm willingly accepted their offer. By its position on the frontiers of France and Germany Strasburg played a part of the highest importance in the political and religious history of the 16th century. Both in the religion and politics of his time Sturm took a prominent part, and on different occasions was sent on missions to France, England, and Denmark. In religion he took sides with Zwingli against Luther, with whose followers in Strasburg he was in constant controversy, which embittered all the later years of his life.

Before Sturm's settlement in Strasburg its magistrates had shown an enlightened interest in public instruction; but guided and inspired by Sturm the town became one of the most important educational centres in Europe. Two years after his arrival (1538) a new gymnasium was established, with Sturm as its rector, and at the same time boarding-houses were erected for poor students with the object of suppressing the mediæval practice of mendicancy. Elementary and secondary education were thus provided for; but it was the ambition of Sturm that the higher studies should also be within reach of every youth of Strasburg. The divided councils of the town, however, and the outlay the organisation of such studies would imply delayed Sturm's scheme till as late as 1564. In that year was founded the Strasburg Academy, which, together with the Gymnasium, supplied a complete course of instruction in all the learning of the time. Sturm's ideal in education was 'to direct the aspiration of the scholars towards God, to develop their intelligence, and to render them useful citizens by teaching them the skill to communicate their thoughts and sentiments with persuasive effect.' In carrying out this ideal, described in his favourite phrase *pictas literata*, Sturm showed his superiority by his judicious gradation of the course of study, and by his novel and attractive methods of instruction. It is his chief praise that beyond all his contemporaries he succeeded in correlating public instruction to the moral and intellectual development of his time. It was little to the credit of Strasburg, therefore, that in his last years he was forced to leave the town through the intolerance of Lutheran zeal. Eventually permitted to return, he died on 3d March 1589. He was a voluminous writer, but, except for the light they throw on the great questions of the 16th century, his works possess no independent value.

See Charles Schmidt, *La Vie et les Travaux de Jean Sturm* (Strasburg, 1855), and German works by Laas (1872) and Kückelhahn (1872).

Sturm und Drang. See GERMANY, p. 188.

Sturt, CHARLES, one of the most resolute of Australian explorers, went as captain of his regiment to Australia, and between 1828 and 1845 headed three important expeditions (see AUSTRALIA, Vol. I. p. 592), from the last of which he returned blinded by hardship and exposure. He held several colonial appointments, and in 1851 received a pension from the first South Australian parliament. He wrote two narratives of his explorations (1833 and 1848), and died in England, 16th June 1869.

Stuttering. See STAMMERING.

Stuttgart, the capital of Würtemberg, stands in a natural basin (817 feet above sea-level) surrounded by hills, which are studded with villas, vineyards, and gardens, and crowned with woods, about 2 miles from the Neckar, and 189 by rail WNW. of Munich, 127 SSE. of Frankfort. Except the churches, most of the public edifices date from the 19th century, and are chiefly built in the Renaissance style. The centre of the place is the Palace Square, upon or near which stand the following buildings—the new royal palace (1746–1807), the old royal castle (16th century), two or three other palaces of the royal family, the Königsbau (shops, bourse, concert-rooms, &c.), the theatre, the railway station (one of the finest in all Germany), the post-office, the Akademie (formerly the Carl School; now library and guardhouse), and the jubilee column (1841), and statues of Schiller and Duke Eberhard. The Collegiate Church, St Leonard's, and the Hospital Church date from the 15th century. The last two, as well as the modern church of St John, are in the Gothic style. The other chief public institutions of Stuttgart are its famous Polytechnic (with 250 students), the Conservatory of Music, the royal library (425,000 vols., with a fine collection of 7000 Bibles), the museum and picture-gallery (fine Thorwaldsen casts), and other collections and educational establishments. Stuttgart ranks next after Leipzig as a centre of the German book-trade. It has, moreover, active industries connected with textiles, beer, pianofortes, chemicals, chocolate, artists' colours, furniture, and has celebrated fairs for books, hops, horses, and cloth. North-east from the palace lies the picturesque royal park (with some good statuary), extending almost all the way to Cannstatt (q.v.). There are an unusually large number of royal seats and palaces in the vicinity of this place, as the Solitude, Hohenheim, Wilhelma, Rosenstein, Berg. Hegel and Hauff were born at Stuttgart. Pop. (1875) 107,573; (1890) 139,659. Stuttgart owes its name and origin to a stud-farm of the early Counts of Würtemberg, and has been the capital since 1482.

Stuyvesant, Peter, governor of New York, was born in Holland in 1602, became governor of Curaçoa, and lost a leg in the attack on St Martin, and in 1646 was appointed captain-general of the New Netherlands. He proved a vigorous but arbitrary ruler, a rigid Sabbatarian, and an indignant opponent of political and religious freedom. Yet he did much for the commercial prosperity of the city, which received its name of New Amsterdam in 1653, and which he would fain have held against the English in 1664, when it became New York. He afterwards lived at his farm—the 'Great Bouwerie,' whose name survives in one of the older streets of the city which soon covered it; and there he died in August 1682.

Stylites, Simeon, the earliest and most famous of the ascetics called Pillar-saints (Gr. *stylites*), had been a monk, and had lived, in the beginning of the 5th century, in extreme seclusion in his Syrian monastery for nine years, without ever moving from his narrow cell. Increasing in enthusiasm he withdrew to Telanessa, near Antioch, where he established himself on the top of a pillar 72 feet high, and only 4 feet square at the top. Here he spent thirty years. During the day he preached to the crowds who gathered at the foot of his pillar; and his admonitions to emperors and empresses were accepted with humility. The fame of his sanctity brought crowds of pilgrims from the most distant countries to see him; and the admiration of his fasting and other austerities is said to have converted many pagans to the church. He died on his pillar in 459, aged seventy-two, and was buried with the greatest pomp at Antioch. A disciple of Simeon, named Daniel, succeeded to his reputation for sanctity, and to his mode of life, which he maintained for thirty-three years, in the still more trying climate of the shores of the Bosporus, about 4 miles from Constantinople. The emperor at length insisted on a covering being placed over the top of the pillar, and Daniel survived till the year 494. In Syria there were many pillar-saints as far down as the 12th century; but in the west Daniel is all but a solitary example. A monk named Wulfailich, near Treves, attempted the pillar-life in the 6th century, but the neighbouring bishops compelled him to desist and destroyed his pillar.

Styptics (Gr. *styptikos*, 'astringent') are agents employed in Surgery for the purpose of checking the flow of blood by application to the bleeding orifice or surface. See Bleeding.

Styria (Ger. *Steiermark*), a duchy of Austria, is bounded on the N. by Upper and Lower Austria, E. by Hungary, S. and W. by Carniola, Carinthia, and Salzburg. Its area is 8629 sq. m., and pop. (1880) 1,213,197; (1890) 1,281,023, who are partly (67 per cent.) of German and partly (33 per cent.) of Slavonic origin. Styria is a mountainous country, traversed in all parts by ramifications of the Alps. The Save and Drave water the southern districts; the Mur, going south to the Drave, flows through the middle of the duchy; while the Enns skirts the north-west boundary. The climate is variable, but generally raw and cold in the northern and more mountainous portion, and mild in valleys and in the south. Forests cover 51½ per cent. of the area; 25½ per cent. is meadows and pastures; and 22 per cent. is under cultivation, producing oats, maize, rye, potatoes, roots for cattle, flax, wine. The chief wealth of the country, however, lies in its mineral products, especially iron; the secondary minerals include salt, coal, graphite, zinc, &c. The chief industries are connected with the production of iron and steel, and their manufacture into such articles as machinery, agricultural implements, wire, and so forth. There are also manufactures of cement, chemicals, candles, cloth, gunpowder, beer, paper, tobacco, and glass. Styria was anciently divided between Noricum and Pannonia, and in the end of the 6th century was colonised by the Wends (Slavs). In 1056 it was separated from Carinthia and made a separate margraviate; and in 1192 it was joined to the Austrian crown, having a few years previously been made a duchy.

Styx (Gr. *stygein*, 'to hate'), one of the rivers of Hades—the tenth part of the waters of Oceanus—flowing round it seven times with dark and sluggish stream, across which Charon ferries the shades of the departed. The nymph of this stream was the daughter of Oceanus and Tethys, and she first, together with her children, came to the help of Zeus against the Titans. For this service they were taken to Olympus, and she herself became the goddess by whom the most solemn oaths of the immortals were sworn. When such an oath was taken Iris brought some of her sacred water in a golden cup, and whoso swore falsely by it lay speechless and breathless for a year, and was banished nine from the councils of the gods.—A rocky stream falling into the Crathis in the north-east of Arcadia bore this name, the scenery around it being fittingly weird and desolate.

Suaheli. See Swahili.

Suakin, or more correctly Sawakin, a seaport of the Red Sea, stands on a small rocky island in a bay on its west side, and is the principal outlet for the commerce of Nubia and of the countries of the Sudan beyond. The island-town is connected with the settlement of El-Keff on the adjacent mainland by a causeway. There are active industries in silver ornaments, knives and spear-heads, and leather-work; but the commerce was, previous to the disturbances which broke out in that quarter in 1883, of much greater moment, being valued at one million sterling annually. Since tranquillity was restored the trade has revived (£103,800 in 1886; £251,700 in 1890; £210,768 in 1891). The more important exports are silver ornaments, ivory, gums, millet, cattle, hides, and gold; the imports, durra, cottons, flour, sugar, rice, ghi, dates, and coal. Here some 6000 or 7000 pilgrims embark every year for Mecca. The Egyptians occupied this port when they extended their power over the Sudan; and in its vicinity several battles were fought between the allied Egyptians and English against the fanatical followers of the Mahdi. Ever since those troubles began Suakin has been held by an English garrison. Pop. 11,000. See Berber; and works by E. G. Parry (1885) and W. Galloway (1888).

Suarez, Francisco, a philosopher and divine of the Roman Catholic Church, was born at Granada on 5th January 1548. As a youth he was so backward that he had considerable difficulty in gaining admission to the order of the Jesuits. But his mind ripened rapidly and developed in some respects unusually high qualities. During the course of his career he taught theology at Segovia, Valladolid, Rome, Alcala, Salamanca, and Coimbra. His theology was a modification of that of Molina (q.v.); he held that in the case of the elect there is a peculiar grace granted, specially adapted to their several individual natures. In formal scholastic philosophy he steered a middle course between realism and nominalism. The most notable of his books were what may be termed the earliest foreshadowing of the modern doctrine of international law (*Tractatus de Legibus ac Deo Legislatore*) and a treatise condemning the extravagant pretensions to kingship put forward by James I. of England. This latter (*Defensio Catholicæ Fidei*) was written in 1613 at the command of the pope. Suarez died at Lisbon on 25th September 1617. His works were published in 23 vols. at Mainz and Lyons in 1630 *et seq.*, and in 29 vols. at Paris in 1859. There is a Life of him by Deschamps (Perpignan, 1671), and another by Werner (2 vols. Ratisbon, 1861).

Subahdar was, under the Mogul government, the title of a governor of a province. It now designates a native officer in the army in India, holding a rank equivalent to that of captain, but subordinate to the European officers.

Sub'altern, in the Army, is an officer below the rank of captain—i.e. a lieutenant or sub-lieutenant.

Subiaco (anc. *Sublaqueum*), a city of Italy, lies embosomed in hills beside the Teverone, 32 miles E. by N. from Rome, and was the cradle of the Benedictine order and the place where the printing-press was first set up in Italy (1464). There are two monasteries dating from the 6th century, one of which (Santa Scolastica) contains a small but valuable library, whilst the other was built near the cave in which St Benedict lived. The city was greatly favoured by Pope Pius VI.: he enlarged its castle (built 1068), erected a church, &c. Pop. 6503.

Sub-lieutenant. See LIEUTENANT.

Sublimation is a chemical process similar to distillation, but differing from it in the nature of the substances to which it is applied. While in distillation *liquids* are converted by the agency of heat into vapour, which is condensed in the liquid form usually by the cooling action of water, in sublimation *solid* bodies are reduced by heat to the state of vapour, which reassumes the solid form on cooling. Sublimation is usually conducted in a single vessel of glass or iron, the product being deposited in the upper part of it in a solid state, while the impure residue remains at the bottom; but in the case of sulphur the vapour is condensed on the walls of a large chamber. Iodine affords a good example of sublimation. On gently heating the lower part of a Florence flask containing a little of this substance a purple vapour rises, which almost immediately condenses in small brilliant dark purple crystals in the upper parts of the flask, while any impurity that may be present remains at the bottom. Amongst the substances obtained by this process, and employed in the Pharmacopœia, are arsenious acid, benzoic acid, corrosive sublimate, and sublimed sulphur.

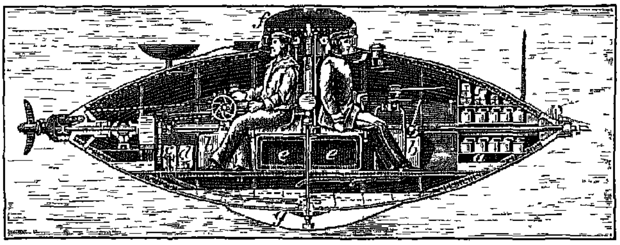
Submarine Mines. See MINES (MILITARY).

Submarine Navigation. When the Diving-bell (q.v.) had shown that air for respiration can be supplied to persons in adequately arranged vessels under water, ingenious men began to speculate on the possibility of navigating closed ships or boats in similarly exceptional circumstances. The first submarine boat on record was constructed in the beginning of the 17th century by a Dutchman named Cornelius Drebell, or Drebelle. She was propelled by oars, and was tried in the Thames by order of James I. She carried twelve rowers, besides passengers. This vessel is alluded to in Robert Boyle's *New Experiments, Physico-Mechanicall, touching the Spring of the Air*, &c. (Oxford, 1660). Pages 363-365 of this curious work contain an account of Drebell's experiment, and state that he accounted his chief secret to be 'the composition of a liquid that would speedily restore to the troubled air such a proportion of vital parts as would make it again for a good while fit for respiration.' The composition of this liquid for enabling the same air to be used again and again was never made public. Bishop Wilkins, who also favoured some other whimsical projects, devoted a whole chapter of his *Mathematicall Magick* (1648) to a dissertation 'Concerning the possibility of framing an Ark for Submarine Navigation.' He here recites the difficulties of the scheme, but evidently considers them not insurmountable; and afterwards he enlarges upon its advantages, in privacy, security from pirates, storms, ice, &c., in naval warfare, philosophical experiments, discoveries, &c. In 1774 an inventor named Day lost his life in an experimental descent in Plymouth Sound in a vessel of about 50 tons burden. One of the most successful machines contrived for submarine navigation was that of Bushnell of Connecticut, which was projected in 1771, and completed in 1775. Bushnell's chief object appears to have been the introduction of submarine warfare. His vessel was propelled by screws, somewhat resembling those now in use for steam-vessels, and there was sufficient air to last for half an hour. In 1800 Robert Fulton, also an American, while residing in France constructed a submarine boat, of which he made many trials, some of them at the expense of the French government, on the Seine, at Brest, and at Rouen. Compressed air was used for respiration, and he remained at a depth of 25 feet for four hours, propelling the boat in any direction; he also successfully attached a torpedo containing gunpowder to the bottom of an old vessel lying in Brest harbour, and blew her up. The vessel patented in 1859 by Mr Delaney of Chicago was egg-shaped in transverse section, and diminished nearly to a point at each end. It had two iron tanks in the interior; one had air pressed into it by an air-pump; the second contained water. The engineer of the boat, by pumping water into or out of the second tank through the action of the air in the first, could raise or lower the boat to different depths in the water. In 1863 the Confederates in Charleston made use of a submarine boat against the blockading Federal squadron. This boat, called a 'David' after her inventor, was built of boiler-plates and propelled by hand by eight men at a maximum speed of four knots; two side-rudders were used for sinking and raising the boat when in motion; she was cigar-shaped, and when advancing to attack her top was just on a level with the surface of the water; three trial trips were made, and each time she sank and failed to rise, the crews perishing before they could be rescued; the fourth trial, however, was successful, and passing out of the harbour she succeeded in blowing up the *Housatonic*, but could not get clear, and was carried down by the *Housatonic*. Several of these 'Davids' were afterwards constructed by the Confederates, but none of them again succeeded in inflicting any serious damage upon the Federal ships.

For some years afterwards, although several experiments were carried out in France and

America, no successful results were arrived at, but in 1886 a submarine boat was built at Stockholm by Nordenfelt. She was driven by steam, and ran 16 miles at a speed of 5 knots, but was only immersed for five minutes at a time; she descended, however, some 30 feet, and this was repeated several times. A similar boat was constructed for and bought by the Greek government. Two others somewhat larger were built by Nordenfelt for the Turkish government, and were tried at Constantinople in 1887; they were 100 feet long, 12 feet in diameter, with a displacement of 160 tons, and when not immersed had a speed of 12 knots, travelling a distance of 100 miles without recoaling; they had a crew of six men, and descended successfully to a depth of about 50 feet. A still later Nordenfelt boat was tried at Southampton, also in 1887; she was 125 feet long, with a diameter of 12 feet, a displacement of 230 tons, and indicated 1000 horse-power with a speed of 15 knots when not immersed; with her cupola awash, however, this speed was reduced to 5 knots. Although these boats at the time seemed to answer all expectations, further experiments would seem to have shown that they could not be depended upon for real practical work, and the original boat, after lying some time at Copenhagen without finding a purchaser, was finally bought and broken up as old iron in 1891.



Section of the French Submarine or Surface Boat *Goubet*, built 1888 : *a*, the electric accumulators; *b*, tanks for compressed air; *c*, *d*, pumps; *e*, *e*, engines; *f*, cupola; *g*, the safety or emergency weight, which, in event of pumps or machines breaking down, can be detached, when the vessel at once rises to the surface. When proceeding on the surface only the cupola, *f*, is visible above water.

By the choice of steam as his motive power the inventor created difficulties not easily to be overcome, and prevented the satisfactory development of that type of boat. One result of this choice was that the boat, when proceeding without communication with the atmosphere, was entirely dependent upon the energy developed by the boiler. That this method of accumulation is disadvantageous is clear from thermo-dynamic principles, which show that from a kilogram of water of 200° centigrade, when it is cooled to 121° C. by the withdrawal of steam, only 2000 m.kg. of work can be obtained. Then not only is the great weight of the engines and boiler a disadvantage, but the continual radiating heat from the boiler renders a prolonged stay in one of these boats impossible when under the surface. An attempt has since been made in England with the Honigman natron-boiler, but with no better results; and later inventors have adopted electric accumulators with electric motor and engines as the motive power. Experiment shows that as much as 8000 m.kg. of work can be developed per kilogram of accumulator weight. In 1888 a boat called the *Nautilus*, designed by a Mr Campbell, was tried in the West India Docks. She was 60 feet long, with a beam of 8 feet, was driven by electricity, and fitted with two impulse tubes for Whitehead torpedoes. The trial was fairly successful.

The nearest approach to a workable submarine boat has been made in two boats built in France, named the *Goubet* and *Gymnote*, and in one, the *Peral*, built at Cadiz. All three have been subjected to exhaustive trials, and with all three a fair measure of success has been obtained. The *Peral*, so called after her designer, a lieutenant in the Spanish navy, was first tried at Cadiz in May 1889. According to the official reports, with 250 accumulators on board she attained a speed of 7 knots, and it is believed that with 616 accumulators a speed of 11 knots would be reached. She covered during two trials some 120 miles without exhausting all the electricity in the accumulators, answered her helm well, and no difficulty appears to have been experienced in sinking or again rising to the surface, although it appears to have been found necessary to rise to the surface before venturing to alter course. A torpedo, of which she is fitted to carry three, was also successfully discharged at a target 400 metres off, while during the six hours she remained closed up, the air on board remained perfectly sweet. In the case of the *Gymnote* and the *Goubet*, with which since 1889 a series of trials have been carried out at Toulon and Cherbourg, the results have been much the same. No difficulty was experienced in sinking and rising to the surface, yet they ran on a perfectly straight course; and when it was wished to turn, the boats were brought to the surface, and placed on their new course before again sinking. When they were moving at a depth of some 15 feet below the surface no trace of their course could be perceived on the top of the water, although in the case of the *Gymnote* at Toulon she was clearly visible and all her movements followed from a captive balloon some 150 feet in the air. The *Goubet* has a displacement of about 2 tons, is 16 feet 5 inches long, 5 feet 10 inches deep, and with a beam of 3·5 feet; outside the boat at the stem she carries a torpedo charged with 110 lb. of dynamite; she carries a detachable keel weighing 900 kilograms, the dropping of which, in the event of the pumping-out arrangements at any time breaking down, would enable the vessel to immediately rise. Her crew consists of only two men. She is fitted with reservoirs for compressed air, electric accumulators, and motor. The *Gymnote* is a boat about as large again. In spite of the relative success which has attended the trials of these three boats, the experiments seem to have revealed certain practical difficulties which render it problematical if submarine navigation can ever be carried on with any degree of safety or certainty. It has been shown that at a depth of only some 50 feet it is impossible to distinguish objects more than 25 feet off, and that even the electric light fails to illuminate objects at a greater distance in the gloom which obtains at this depth; the colour of the water at this depth is a deep green, and red objects are completely invisible. Navigation under these circumstances must always be dangerous. In the French and Spanish experiments a given course seems to have been steered with mathematical accuracy by means of the gyroscope, but to deviate from this course would appear at present to be difficult without those in the boat losing all knowledge of their whereabouts, and thus being forced to come to the surface to reconnoitre; and the slow speed at present attainable, not exceeding 7 to 8 knots, also militates against the possible usefulness of these boats. Where they seem really to have achieved a great success is when moving just below the surface of the water with the optical glass, which is only about the thickness of a man's fist, showing above the surface. By means of the optical glass a reflection of the objects passed, such as the hull of a vessel, is caught on a lens and then projected on to a suitable plate in view of the person steering. When the boat is completely below the surface this image, although not strongly defined, is still sufficiently marked. The success of the *Goubet*, when tested by a special commission, led to the construction of another and larger boat, the *Sirène*, 130 feet long. See also the article Torpedoes.

Submarine Telegraphs. See Telegraphy, and Atlantic Telegraph.

Subpœna, in English law practice, means the writ or process by which the attendance of a party or witness in a court of justice is compelled. It is a writ in the Queen's name commanding him to lay aside his business and all excuses, and attend at the time and place indicated, under a penalty. If the witness is required to produce a document the writ is called a *subpœna duces tecum*. If the person summoned do not attend and has not a good legal excuse, such as dangerous illness, he may be sued in an action of damages or committed to prison.

Subsidence. See Upheaval.

Subsidies, parliamentary grants to the crown, levied on persons in the form of so much on the pound for land or goods; or grants of special sums from customs duties (see Customs Duties, Taxation). The term is used to denote money paid by one state to another in order to procure a limited succour of auxiliary troops, ships of war, or provisions. Thus, in the time of the war with the revolutionists of France and Napoleon I., Great Britain furnished subsidies to foreign powers to a large extent in order to engage them to resist the progress of the French.

Substance is a term which has played a great part in philosophical and theological discussion. It occurs first in the Aristotelian enumeration of categories, where *οὐσία* is in a manner opposed to the other nine categories of attribution and relation. This contrast is expressed in the correlation of the Latin terms substance and accident. Substance is defined as that which exists *per se*, whereas attributes or accidents exist *in alio*. The substance, in other words, is regarded as an independent existence, a permanent subject of which the accidents are predicated, and to which they belong as its qualities or states. Individual things were thus treated by Aristotle and the scholastics as existing *per se*; they are, in the Aristotelian phrase, 'the first substances.' To the objection which readily occurs that God alone is in this sense substance—i.e. truly self-subsistent—they replied by the distinction between *per se* and *a se*. If the world is not to be resolved into a flux of accidents, created substances must exist *per se*; but God alone exists *a se* or absolutely. The same distinction—between created substances and God as the one absolutely independent substance—reappears in Descartes, but is repudiated by Spinoza, who thus reaches his completely pantheistic doctrine of the *unica substantia*. In English philosophy the aspect of substance made most prominent is that of an underlying 'substratum' (the Greek *ὑποκείμενον*) or unknown 'support' of the qualities we know. Locke, like Descartes, believed in two classes of substances, material and spiritual; but the negative criticism of Berkeley was brought to bear against the first class, while Hume directed the same battery against the spiritual substances which the bishop had spared, and thus pulverised the world into unsupported accidents. All our perceptions, Hume declares, 'may exist separately, and have no need of anything else to support their existence.' The criticism, however, which is valid against the peculiar form which the doctrine of substance had assumed in Locke ignores the really indispensable character of the conception. The notion of substance as something over and above the qualities—an inaccessible somewhat, hidden behind the qualities instead of being revealed by them—is undoubtedly false. But a pure phenomenalism can yield no theory of knowing or being. The world, as it has been said, is not a flight of adjectives; qualities do not fly loose; they are necessarily unified in a substance or subject. In recent philosophy the misleading idea of a substratum reappears in the Kantian theory of the unknowable thing-in-itself, which in turn develops into the characteristic doctrine of modern agnosticism.

Subways. The term subway has been most generally applied to arched passages or small tunnels under streets for the purpose of containing gas-pipes, water-pipes, and sometimes sewer-pipes, or at least drains for surface-water. Some also contain telegraph-wires and pipes for the transmission of compressed air. They are made of sufficient size to permit of workmen walking to and fro in them to examine the pipes and to execute repairs. It need hardly be said that in large towns such subways are a great public benefit. They save the necessity for breaking up streets to get at the pipes for repairs, an operation which not only obstructs the traffic, but prevents the roadways and foot-pavements from being kept in proper condition. Paris has long had an extensive system of subways for the purposes above noted. These are built of stone, and are of various shapes, being circular, oval, or egg shaped, or with straight sides and semicircular top. The lower portions of them are stepped for footpaths, with a track for the drain between these. A number of these subways have been constructed in London—in Southwark Street, Queen Victoria Street, and the Thames Embankment, for example. The subway under the roadway of the Boulevard Sebastopol, one of the largest in Paris, is 16 feet wide and 11 feet high; that under the footway of the Thames Embankment is 9 feet wide and 7 feet 3 inches high.

Another class of subways which has been extensively constructed of late years both in Britain and abroad comprises arched passages under railways to enable passengers to pass from one side to another of a station, or to communicate between two adjacent railway stations. In some cases these are elaborate examples of underground engineering, and when they are faced with glazed bricks, as most of them are, they have a clean and elegant appearance.

The name subway was in general use during its construction for the deep tunnel electric railway between the City and Southwark, now called the City and South London Railway, which was opened in 1890. Two separate tunnels were made for this line—one for the up and another for the down traffic. These are from 45 to 60 feet below the surface of the ground, each consisting of a cast-iron tube 10 feet in diameter, and formed of segments bolted together. At the stations the passengers descend and ascend by hydraulic lifts, unless they prefer to use the stairs. It is proposed to construct in a similar manner the projected Central London Railway from the heart of the City to the extreme west end of the metropolis. See Tunnel.

Consult the *Proceedings of Civil Engineers*, vol. xxiv., for the drains and subways of London and Paris; *Les Promenades de Paris* (1873), for sections of the Paris subways; and *Engineering*, vols. xlix. and l. (1890), for papers on the City and Southwark subway.

Succession, *a term used technically* in Roman and Scots law (but not in English law) to denote *the taking of property by one person in place of another.* The order of succession in Roman and Scots law differs in several respects from that in English law. See HEIR, KIN (NEXT OF), EXECUTOR, HUSBAND AND WIFE, LEGITIM. For legacy and succession duties, see LEGACY and the almanacs. For APOSTOLIC SUCCESSION, see under that heading.

Succession Acts. From a comparatively early period in English history parliament occasionally exercised the power of limiting or modifying the hereditary succession to the throne. The first instance of such interference occurred in the case of Henry IV.; and parliamentary interposition was subsequently exercised in the case of *Henry VII. and in regard to the immediate* successors of Henry VIII. The respective rights of James I., Charles I., and Charles II. were acknowledged by parliament. The revolution of 1688 was founded on the so-called abdication of the government by James II. The Convention bestowed the crown on William and Mary for life, and regulated the claims of Anne. In view of the impending extinction of the Protestant descendants of Charles I. the crown was settled by 12 and 13 Will. III. chap. 2, in the event of the death of William and Anne without issue, on the next Protestant line, according to the regular order of succession—viz. the descendants of the Electress Sophia of Hanover, granddaughter of James I.; and it was at the same time enacted that whoever should hereafter come to possession of the crown should join the communion of the Church of England as by law established (see GEORGE I., HANOVER). This is the latest parliamentary limitation of the crown; but the right of parliament to limit the succession was secured by 6 Anne, chap. 7.

Succession Wars is the general name given to contests which took place in Europe during the 18th century on the extinction of certain dynasties or ruling houses. Four such wars are usually enumerated—that of the Spanish succession (1701-13), of the Polish succession (1733-38), of the Austrian succession (1740-48), and of the Bavarian succession (1777-79). The first and third alone are of sufficient general historical interest to be noticed here.

(1) WAR OF THE SPANISH SUCCESSION. Charles II., king of Spain, having died without direct descendants in November 1700, claims were raised to the vacant throne by the husbands of his two sisters, Louis XIV. of France, who had married the elder, and the Emperor Leopold I., who had married the younger. Both these monarchs were also themselves grandsons of Philip III. of Spain; but neither desired the Spanish crown for his own head. Louis put forward his grandson Philip of Anjou; whilst Leopold advocated the claims of his second son, the Archduke Charles. The Electoral prince Joseph of Bavaria, grandson of the Emperor Leopold, was the heir originally designated in King Charles's will, but he died in the beginning of 1699. Both Louis XIV. and his wife had nine years before solemnly renounced the crown of Spain for themselves and their heirs; nevertheless, after Joseph of Bavaria died the agent of Louis XIV. induced Charles of Spain to nominate Philip of Anjou as his successor. Three months after the Spanish monarch's death the French prince entered Madrid, and was crowned as Philip V.; and his accession was at first recognised by all the European powers except the emperor. Louis, however, soon provoked the United Netherlands and England, and they joined Austria for the purpose of armed opposition to France.

Hostilities were begun by Prince Eugene in Italy *in 1701; and in the following year the conflict* raged not only in Italy but also in the Netherlands and in Swabia. At first the allies were victorious all along the line: Marlborough took the fortresses on the Meuse and overran the electorate of Cologne; *and the Landgrave of Baden had the good fortune* to drive back the most redoubtable of the French commanders, Villars, who had crossed the Rhine from Alsace. But the aspect of things was altered in 1703 by Villars, in conjunction with the Elector of Bavaria, penetrating as far as the Tyrol and capturing Passau, whilst the imperialists in Italy were more than held in check by Vendôme. But in the campaign of 1704 Marlborough and Eugene, acting in concert, inflicted a crushing defeat upon their opponents at Blenheim (q.v.) and drove them back into France. Two years later the forces of Louis were compelled to withdraw from the Netherlands owing to Marlborough's great victory of *Ramillies and his capture of the principal Flemish* towns. At the same time Eugene and his relative the Duke of Savoy routed the French near Turin and swept them out of North Italy. Meanwhile the war had extended to the Iberian peninsula. The king of Portugal declared for the allies, and Archduke Charles made himself master of Catalonia, and even for a time held possession of Madrid. The English captured Gibraltar in 1704; but they and the Portuguese sustained a severe defeat from the Duke of Berwick (commanding the French forces) at Almanza in 1707. In this latter *year Louis, feeling the severity of the strain,* opened negotiations for a settlement. But the allies, having the upper hand, thought to humble him yet more, and the war went on.

An attempt of Vendôme and the Duke of Burgundy to reconquer the Spanish Netherlands in 1708 was frustrated by Marlborough and Eugene, who routed them at Oudenarde; and in the next year they defeated at Malplaquet the hitherto invincible Villars. Yet just when the fortunes of Louis seemed to be at their worst, circumstances intervened in his favour. In England the Whigs were supplanted by the Tories, who voted for peace; and in Austria the Emperor Leopold died, and was succeeded by the Archduke Charles. Accordingly the war languished, and, Philip V. having pledged himself that the crowns of Spain and France should not be united, all the allies, except the emperor, signed the treaty of Utrecht (q.v.) on 11th April 1713. The emperor, too, was brought to terms after Villars had overrun the Palatinate and Baden, and he signed peace at Rastatt (7th March 1714), whereby he acknowledged Philip as king of Spain, and became himself the ruler of the Spanish Netherlands, Naples, Milan, and Sardinia.

Paris, 1886); Von Noorden, *Der Spanische Erbfolgekrieg* (3 vols. Düsseldorf, 1870-82); Arneth, *Prinz Eugen von Savoyen* (3 vols. Vienna, 1858); and the articles EUGENE, MARLBOROUGH, PETERBOROUGH, VILLARS, &c. in this work.

(2) WAR OF THE AUSTRIAN SUCCESSION. The Emperor Charles VI. died in 1740, leaving his hereditary dominions—Bohemia, Hungary, and the archduchy of Austria—to his daughter Maria Theresa. She was at once beset by enemies, eager to profit from the presumed weakness of a feminine ruler. The Elector Charles Albert of Bavaria, who

had refused his signature to the Pragmatic Sanction (q.v.), demanded the imperial crown as the descendant of the Emperor Ferdinand I., and he was backed up by France and Spain. Augustus of Saxony and Poland advanced his claim as being the husband of the eldest daughter of the Emperor Joseph I. Frederick the Great of Prussia seized the opportunity to wrest Silesia, which he greatly coveted, from the crown of Austria. The Bavarians and the French (under Belleisle) invaded Bohemia, and crowned the elector king of that country at Prague on 19th December 1741. About two months later he assumed the imperial crown at Frankfort-on-Main; yet on the very next day his own capital (Munich) was occupied by the Austrian general Khevenhuller, who, assisted by the high-spirited Hungarians, had advanced up the Danube, and now speedily overran Bavaria. A few months later the empress-queen bought off her most dangerous antagonist, Frederick, by giving up to him Silesia. At this time, too, Augustus of Saxony, who had at first made common cause with the French and the Bavarians, withdrew from the contest and made peace with Maria Theresa. In the end of 1742 the Austrians were forced out of Bavaria and the French evacuated Bohemia. The English, who from the first paid a substantial subsidy to Austria, took up arms on her behalf in this same year, and in 1743 defeated the French at Dettingen in Bavaria. In this year the Austrians repossessed themselves of the Elector Charles Albert's dominions. Saxony now joined the allies and took the field against his former associates. On the other hand, Frederick renewed hostilities and invaded Bohemia; but after a short interval he was once more willing to make peace. About this juncture Charles Albert died, and his son and successor abandoned his father's pretensions to Maria Theresa's dominions. This left France to carry on the struggle alone. But whilst Austria had the better of the war in Italy, Marshal Saxe captured several of the Flemish fortresses, won the victories of Fontenoy (1745), Rocoux (1746), and Lawfeldt (1747), and reduced the Austrian (formerly Spanish) Netherlands. Peace was at length concluded at Aix-la-Chapelle on 18th October 1748, things remaining pretty much *in statu quo*, except that Frederick was allowed to retain Silesia.

See Arneth, *Geschichte Maria Theresias* (10 vols. Vienna, 1863-79); and MARIA THERESA, SAXE, &c.

Succinic Acid derives its name from its having been originally found in amber (Lat. *succinum*). Succinic acid occurs as a natural constituent not only in amber, but also in the resins of many of the pine tribe, in the leaves of the lettuce and wormwood; and in the animal kingdom it has been detected in the fluids of hydatid cysts and hydrocele, in the parenchymatous juices of the thymus gland of the calf, and of the pancreas and thyroid gland of the ox. Succinic acid is convertible into tartaric acid, and conversely.

Succory. See CHICORY.

Succoth. See PITHOM.

Succubus. See DEMONOLOGY.

Succulent Plants, a descriptive phrase applied to the Crassulaceæ, Cactaceæ, Euphorbiaceæ, Mesembryaceæ, some Liliaceæ, &c.

Suchet, LOUIS-GABRIEL, Duc d'Albufera, and marshal of France, was born, son of a silk manufacturer, at Lyons, 2d March 1770. At twenty-two he volunteered into the cavalry of the Lyons national guard, next fought in Italy, and by his conspicuous courage and ability at Lodi, Rivoli, Castiglione, Arcola, and a hundred battles, had risen by 1798 to be general of brigade. He added to his reputation in Egypt and again in Italy, served as general of division under Joubert in 1799, and the year after was second in command to Masséna. He covered himself with glory by checking a vastly superior Austrian force under Melas (1800), and so preventing the invasion of the south of France. He took a distinguished part in the campaigns against Austria (1805) and Prussia (1806), and was subsequently (April 1809) appointed generalissimo of the French army in Aragon—his first independent command. By marvellous tact no less than military skill he reduced this stubborn province to complete submission within two years. He conquered at Maria and Lerida, and took Tortosa and Tarragona, for which he was rewarded with a marshal's baton. In 1812 he destroyed the army of Blake at Sagunto, and on the 9th January of that year captured Valencia, earning the title of Duke of Albufera. The details of his five Spanish campaigns have been well given by him in his *Mémoires sur ses Campagnes en Espagne* (2 vols. Paris, 1829-34). He was created a peer of France by Louis XVIII., but joined Napoleon after his return from Elba, and was charged with the defence of the south-west frontier. Deprived of his peerage after the disaster of Waterloo, he did not return to court till it was restored in 1819. He died at the château of Saint-Joseph, near Marseilles, 3d January 1826. O'Meara and Las Cases tell us that of his generals Napoleon ranked Masséna first and Suchet second.

Sucking-fish, a name sometimes given to the Remora (q.v.) or Echeneis, which has a dorsal sucker, and to other fishes which have a sucker formed by the union of the ventral fins—e.g. *Cyclopterus lumpus*, the Lumpsucker (q.v.). To the members of the carp-like Catostomidæ, almost exclusively confined to the rivers of North America, the name sucker is also applied, in allusion to their mode of sucking up their food, which consists of small aquatic animals.

Suckling, SIR JOHN, poet, was born at Whitton in Middlesex, and baptised February 10, 1609. He was of good family on both sides, and his maternal uncle, Sir Lionel Cranfield, became Earl of Middlesex; his father held office as a secretary of state and comptroller of the household under James I., and was made privy-councillor by Charles I. Suckling may have been at Westminster, as Aubrey says, but certain it is that in 1623 he entered Trinity College, Cambridge, five years later went on his travels abroad, and served for some time in Germany under Gustavus Adolphus. He returned about 1632, and soon became 'the darling of the court,' distinguished before all by his wit and prodigality. An inveterate gambler, he spent his days and nights at cards and bowls, his intervals divided betwixt gallantry and verse-making. In April 1635 he appeared before the Star-chamber for breaking the statute passed in the eighth year of Charles to require all landowners to spend some time on their estates. To aid the king against the Scots he raised a troop of 100 horse, and equipped them so handsomely that it is said to have cost him about £12,000. They rode north with the king, but shared the shame of the rout before the Scots at Duns. The lampoon by Sir John Mennis has commemorated the cowardice of Suckling and his gay cavaliers, but in reality they behaved no worse than the rest of the royal army. Suckling was returned to the Long Parliament for Bramber, joined in the abortive plot to rescue Strafford from the Tower, and in more desperate plots still against the liberties of the kingdom by means of French and Irish troops, and his schemes being discovered he fled for safety to the Continent. Impoverished and disgraced, it is almost certain that he poisoned himself at Paris before the close of 1642. The works of Suckling consist of four plays, *Aglaura*, *The Goblins*, *Brennoralt*, and *The Sad One*, now utterly forgotten; a prose treatise entitled *An Account of Religion by Reason;* a few *Letters*, written in an artificial style; and a series of miscellaneous poems, beginning with *A Sessions of the Poets*, published in 1637, which is original in style, and happily descriptive of the author's contemporaries. But the fame of Suckling rests on his songs and ballads, which at their best are inimitable for ease, gaiety, and grace. The well-known *Ballad upon a Wedding* is an exquisite masterpiece of sparkling gaiety and felicity of phrase; and his lyrics 'I prithee send me back my heart,' 'Why so pale and wan, fond lover?' are amongst the triumphs of English verse.

See the Rev. Alfred Suckling's *Selections, with a Life* (1836), reproduced by W. C. Hazlitt, with the addition of a few gross poems and portions of poems, poor beyond most of their kind (2 vols. 1874); also the Memoir prefixed to F. A. Stokes's edition (New York, 1885).

Sucre. See CHUQUISACA.

Sudamina, or MILIARY ERUPTION, is one of the vesicular diseases of the skin. The former name indicates that the disorder is associated with profuse sweating, though it occasionally occurs in a dry skin; the latter has reference to the size of the vesicles, which do not exceed those of a millet-seed. The vesicles are most abundant on the neck and trunk, and are sometimes attended with itching. They almost always occur in association with febrile disorders, particularly acute Rheumatism (q.v.), which, however, do not seem in any way modified by them. They give rise to little irritation, and are of no particular importance.

Sudan. See SOUDAN.

Sudbury, a municipal borough (till 1843 also parliamentary) of Suffolk, on the Stour at the Essex boundary, 16 miles S. of Bury St Edmunds and 58 NE. of London. It has three old churches, mainly Perpendicular in style, a town-hall (1828), grammar-school (1491; rebuilt 1857), corn exchange (1841), and manufactures of cocoa-nut matting, silk, bricks, &c.—the famous woollen industry of the Flemings, dating from the 14th century, having died out. Simon Theobald, Archbishop of Canterbury, beheaded by Tyler in 1381, and Gainsborough were natives. Pop. (1851) 6043; (1891) 7059.

Sudbury, a village of Ontario (pop. 800), by rail 443 miles W. by N. of Montreal and 179 NE. of Sault Ste Marie. It is notable for the immense deposits of copper and nickel close by. Two short branch-lines connect Sudbury and the mines, and smelting-furnaces reduce the ores on the spot.

Sudermann, HERMANN, poet and novelist, was born 30th September 1857 at Matzicken in East Prussia, studied at Königsberg and Berlin, and while acting as domestic tutor, and as editor of a small newspaper, produced tales, tragedies, and poems that were unheeded. But the drama *Ehre*, on somewhat realistic lines, was produced in 1888, and made him famous; and his novels, *Frau Sorge* (1888; Eng. trans. *Dame Care*, 1892), *Der Katzensteg* (1889), *Im Zwielicht, Iolanthes Hochzeit* (1892), &c., have been widely read. The censor of plays forbade the representation of the tragedy *Sodoms Ende* (1890).

Sudetic Mountains, an extensive mountain-system in the south-east of Germany, dividing Prussian Silesia and Lusatia from Bohemia and Moravia, and connecting the Carpathians with the mountains of Franconia. It does not form a continuous chain except in the middle, where it is known under the names of Riesengebirge (q.v.) and Isergebirge. The subsidiary chains range on an average from 2500 to 3300 feet in altitude.

Sudorifics, or DIAPHORETICS, remedies to excite the secretions of the skin. The simplest of all diaphoretics are baths, which may be warm baths of water or vapour, either simple or medicated (see BATH). The most powerful of all, however, as regards educing perspiration is probably the Turkish bath, which consists essentially in the use of a sweating process by means of air heated to a temperature of 140°, or even more. The following remedies, used internally, are powerful diaphoretics: antimony, ipecacuanha, opium (these three either singly or in combination); ammonia, and the carbonate or acetate of ammonia (spirit of mindererus), guaiacum, dulcamara, and sassafras; and, most active of all, pilocarpine, the chief active principle of jaborandi. On most of these substances special articles will be found. A favourite formula is Dover's Powder (q.v.), consisting of a grain of opium, and a grain of ipecacuanha in each ten grains of the powder. This in doses of from five to eight grains, followed by warm drinks and plenty of blankets in bed, usually produces copious perspiration, and is very soothing and useful in many commencing inflammatory and febrile complaints. James's powder (antimonial), in doses of from three to five grains, is often added to the above in domestic prescriptions; but neither of these medicines should be used rashly, as in certain states of the system they may prove dangerous; and they should never be given to very young children.

Sûdra. See CASTE.

Sudreys, or SUDOREYS. See MAN (ISLE OF).

Sue, MARIE-JOSEPH-EUGÈNE, a master of melodramatic fiction, was born at Paris, 10th December 1804. The son of an army surgeon, he himself served as such in Spain and at Navarino, and worked up his experiences into the Byronic and absurd novels, *Kernock le Pirate*, *La Salamandre*, &c., as well as the unhistorical *Histoire de la Marine Française* (5 vols. 1835–37) and *Histoire de la Marine Militaire chez tous les Peuples* (1841). In 1829 his father died leaving him a handsome fortune, which enabled him to give himself seriously to literature. His first hit was the too famous *Mystères de Paris* (10 vols. 1842), which first appeared in the columns of the *Journal des Débats*. Its successor, *Le Juif Errant*, which appeared in the *Constitutionnel* (10 vols. 1845), was no less successful. Later works were *Martin, l'Enfant Trouvé* (12 vols. 1846), *Les Sept Péchés Capitaux* (16 vols. 1847–49), and *Les Mystères du Peuple* (16 vols. 1849), the last condemned by the law-courts of Paris as immoral and seditious. Sue was elected deputy for Seine in 1850, and attached himself to the Extreme Left. The *coup d'état* of December 1852 drove him into exile. He lived at Annecy in Savoy, and there died 3d August 1859.

Sue was often grouped with his contemporary Dumas, but is far his inferior in breadth, humanity, and interest generally. But he possesses undeniably the power of holding a reader fast in his story, and if his novels are never re-read and soon forgotten, at least they are read once in a fever of curiosity. Unfortunately their author was nothing of an artist, so that they possess as little excellence in form as in substance. Indeed these novels are hardly to be taken seriously as works of art, yet they have the vitality that ever belongs to a group of strong situations, however improbable. As for the unhealthy thread that runs throughout, that is nowadays no disqualification far beyond the bounds of France.

Suet is a variety of solid fatty tissue, which accumulates in considerable quantity about the kidneys and the omentum of several domestic animals, especially the ox and sheep. Beef suet is extensively used in cookery, while purified mutton suet under the name of *Sevum Præparatum* occurs in the Pharmacopœia, and is obtained by melting and straining the internal abdominal fat. It consists of a mixture of the ordinary animal fats, with a great preponderance of the most solid of them—viz. stearin, which constitutes about three-fourths of the whole. The pure suet of the Pharmacopœia is 'white, soft, smooth, almost scentless; and is fusible at 103° (39·4° C.).' It is used as an ingredient in plasters and ointments. Ordinary melted suet is frequently employed in the same manner as lard, to preserve potted meats, fish, &c. from the action of the air. See FATS.

Suetonius. CAIUS SUETONIUS TRANQUILLUS, grammarian, critic, and chronicler, was contemporary with Domitian, Trajan, and Hadrian, having been born (birthplace and parentage unknown) under Vespasian. Of his manhood we find some traces in the letters of the younger Pliny, who, when appointed by Trajan proconsul of Bithynia, took Suetonius with him. Pliny's friendship, manifested in bringing him under the emperor's notice as 'probissimum, honestissimum, eruditissimum virum,' procured him means and leisure enough for literature, of which he was a professed votary. After Pliny's death he was befriended by C. Septicius Clarus, prefect of the prætorians, to whom he dedicated his best-known work, in eight books, *The Lives of the First Twelve Cæsars*. He became Hadrian's private secretary, a post he long held till, compromised in a court intrigue, he forfeited it, to devote himself entirely to literature. He was then about fifty years of age, but no further incident of his life is known to us.

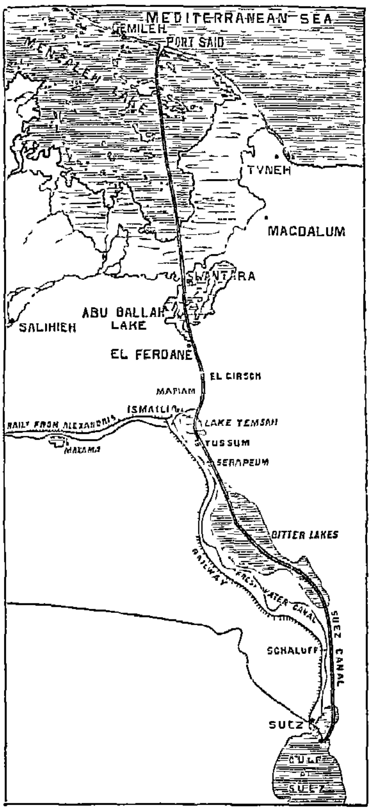
In the compilation of his *Lives* Suetonius must have had before him the Annals and Histories of Tacitus; perhaps (according to some scholars) the *Lives* of Plutarch. But he has neither the dramatic power of the Roman nor the philosophy of the Greek. The Augustan historian Vopiscus praises him as a 'most finished and impartial writer' (*emendatissimus et candidissimus scriptor*)—merits which later criticism still allows him. His method, indeed, is of the simplest. After detailing the emperor's family history, he describes his youth and manhood till he assumes the purple; after this he abandons the chronological order and dwells on the character of his subject, as shown in public and private, according to virtues and vices, irrespective of periods of life; next he reverts to the order of time in relating the portents of death, the mode of death itself, and the terms of the emperor's will. Ever anxious to exclude uncertainty from his narrative, he deals with ascertained fact and does nothing by interposed discussion to bias the reader's judgment one way or another. With no affectation of epigram, his brevity is masterly, and probably no writer ever compressed so much that is interesting into so brief a space. He had many imitators (St Jerome among them) in antiquity and in the middle ages. His other works, *De Illustribus Grammaticis* (of which a complete copy existed in the 15th century) and *De Claris Rhetoribus*, need only be mentioned here, as also the fragmentary lives of Terence, Horace, Persius, Lucan, Juvenal, and Pliny.

British scholarship has done nothing for the text or exegesis of Suetonius. After the *editio princeps* (Rome, 1470), the best are those of Casaubon (1596 and 1610), F. A. Wolf (1802), Roth, with admirable prolegomena (1857), and Reifferscheid (1860). See also D. Ruhnken's *Scholia* (Leyd. 1888). Of translations those of Adolf Stahr in German (1864) and of Rigutini in Italian (1882, with Roth's text) are among the best. That in Bohn's Classical Library is fair. For Suetonius Paulinus, the Roman governor of Britain, see BOADICEA.

Suevi. See SWABIA.

Suez, a town of Egypt, is situated at the southern extremity of the Suez Canal and on the Gulf of Suez, a northern arm of the Red Sea. Close beside the town the Peninsular and Oriental Steamship Company have extensive storehouses and magazines, there is a large English hospital, and the sweet-water canal from Ismailia terminates here. The railway from Ismailia runs through the town on to the spacious harbour 2 miles beyond. The streets are generally neglected and uneven, and by night unlighted. Suez has not a very large trade of its own (£800,000 to £900,000 annually); most of the commerce passes through it without making halt. Pop. (1890) 13,000. The town is surrounded by the desert. At more than one period in the past this place was the seat of a flourishing trade, as for instance in the time of the Ptolemies, when it was called Arsinoe; under the first Moslem rulers of Egypt, who called it Kolzum, the Greek name being then Clysma; and from the 16th to the 18th century, when it formed an important *étape* in the European trade with India; but by the beginning of the 19th century it was again quite decayed. It began to revive when the overland mail route between England and India was opened in 1837, and has improved yet more since the completion of the canal.

SUEZ CANAL.—The ancient Egyptian king, Rameses II., seems to have been the first to excavate a canal between the Nile delta and the Red Sea. This, having been allowed to fill up and become disused, was reopened by Darius I. of Persia. It was once more cleared and made serviceable for the passage of boats by the Arab conquerors of Egypt. The plan of connecting the Mediterranean and the Red Sea by means of a canal wide enough to admit of the passage of ocean-going vessels caught the attention of Napoleon, and he commissioned the engineer Lepère in 1798 to examine and report to him as to the practicability of the idea. This expert's opinion, which was *de facto* erroneous, that the surface of the Red Sea was nearly 30 feet higher than that of the Mediterranean, put an end to the project. But the mistake having been corrected by English officers in 1841, the French engineer Lesseps (q.v.) set himself (in 1849) to study the isthmus more thoroughly, and in 1854 he managed to enlist the interest of Said Pasha, khedive of Egypt, in his scheme. Two years later the Porte granted its permission and the Universal Company of the Maritime Suez Canal was formed, receiving important concessions from the ruler of Egypt. Half the capital was raised by public subscription in Europe, chiefly in France; the other half was contributed by the khedive. The first spadeful of earth was turned at Port Said, the Mediterranean terminus of the canal, on 25th April 1859. Soon from 25,000 to 30,000 men were at work excavating. But in 1862 progress was greatly delayed owing to the necessity of first completing the canal that was to bring drinking-water from the Nile to Ismailia, near the middle point of the isthmus, and thence carry it southwards to Suez on the Red Sea; moreover the new viceroy, Ismail, refused to ratify the concessions that had been made to the company; it was, however, agreed to let him buy them back for the sum of £3,800,000. This hindrance being removed, the work went on again; and at length, on 16th November 1869, the canal was duly opened for vessels. It had cost altogether about 20 million pounds. The total length is 100 miles; the width of the water-surface was at first 150 to 300 feet, the width at the bottom 72 feet, and the minimum depth 26 feet. At Port Said two strong breakwaters, 6940 and 6020 feet long respectively, were run out into the Mediterranean; at Suez another substantial mole was constructed. The making of the canal was facilitated by the existence of three or four valleys or depressions (formerly lakes), which, when the water reached them, became converted into lakes. Immediately south of Port Said the canal crosses Lake Menzaleh (28 miles long); and three more—Lake Ballah, Lake Timsah (5 miles long), and the Bitter Lakes (23 miles)—are traversed to the south of it. The highest point or elevation that was cut through does not exceed 50 feet above sea-level. At intervals of 5 or 6 miles 'sidings' or side-basins are provided to enable vessels to pass one another. At the end of a dozen years the traffic had increased so enormously that a second canal began to be talked about; and in 1886 the task of widening, and also deepening, the existing canal was commenced. By 1890 the canal had been deepened to 28 feet, and widened between Port Said and the Bitter Lakes to 144 feet, and from the Bitter Lakes to Suez to 213 feet.



Map of Suez Canal.

The steadily increasing use of screw-propellers in steam-vessels, combined with the enormous shortening of sea-voyages to India, China, and Australia effected by passing through the canal, caused the tonnage of the vessels using this route to increase at a wonderfully rapid rate. The subjoined table gives the salient particulars :

Year.	No. of Vessels.	Tonnage.	Receipts
1870	486	654,915	£206,373
1875	1264	2,423,672	994,375
1880	2026	4,344,519	1,629,577
1885	3624	8,985,411	2,488,297
1890	3389	9,749,129	2,680,436

Both in respect of tonnage and of the number of vessels Great Britain greatly exceeds all other nations put together: in 1890, 2522 of the vessels were British, their tonnage reaching the aggregate of 7,438,682 tons. Since 1886 the time of making the transit through the canal has been greatly accelerated. In that year a vessel took on an average thirty-six hours to get through; but in 1890 the average time of passage did not much exceed *twenty-four hours*. Moreover, since 1st March 1887 the electric light has been used to light the way during the night. The first year that this adjunct was in operation it was used by 395 vessels out of 3137; in the year 1890, 2836 out of 3389 used it. The cost of getting through by electric light amounts to about £10 for each vessel. Besides 100,000 founders' shares, the original capital of the company consisted of 400,000 shares of £20 each, making a sum total of £8,000,000. Of these shares 176,602, which belonged to the khedive, were purchased from him by Beaconsfield for the British government in 1875 for the sum of £3,976,582, although he had mortgaged the interest on them up to the year 1894. Since the formation of the company additional obligations have been incurred to the amount of £8,110,567. All net earnings that remain after 5 per cent. interest has been paid are divided in the following proportions: 71 per cent. as dividend to the shareholders, 15 per cent. to the khedive, 10 per cent. to the holders of founders' shares, 2 per cent. to the managing directors, and 2 per cent. to the company's employees. In 1890 the net profits thus divided amounted to £1,525,335.

See F. de Lesseps, *Le Canal de Suez* (Paris, 1875), and *Lettres, Journal, et Documents à l'Histoire du Canal de Suez* (5 vols. Paris, 1881); *Journal of the Statistical Society* (June 1887); *Suez Canal, Returns of Shipping and Tonnage, 1888–91* (Lond. 1891); the Budget speech of Mr Goschen (1892); *Le Canal de Suez* (Paris, every ten days).

Suffioni, name given to the exhalations of hot sulphurous vapours, which are common in volcanic regions. See VOLCANO.

Suffocation. See ASPHYXIA, RESPIRATION, STRANGULATION.

Suffolk, the easternmost county of England, is bounded on the N. by Norfolk, E. by the German Ocean, S. by Essex, and W. by Cambridgeshire. In length from east to west it measures 57 miles, and the mean breadth from north to south is about 30 miles. Area, 1475 sq. m. ; pop. (1801) 210,431; (1831) 296,317; (1861) 337,070; (1891) 369,351. Though no hills of any notable character rise within its confines, Suffolk is not by any means flat. Bordering on the seacoast, it is low and skirted by banks of shingle, except near Lowestoft and Southwold, and again at Dunwich and Felixstowe, which all rest on sandstone cliffs; adjoining and running parallel with these last stretches an almost continuous series of light sandy heath-lands, glorious in summer with gorse and heather; and inland the country is undulating, well watered, and for the most part well wooded, the scenery in places—e.g. at Yoxford, aptly called the garden of Suffolk, and in the vale of the Gipping—being very picturesque. More than two-thirds of the county consists of heavy land, a stiff clay prevailing in Mid (or as it is locally termed 'High') Suffolk, whilst the western part lies upon chalk, terminating at its north-west corner with a tract of peaty fen-land. The Waveney, Alde, Deben, Orwell, and Stour, all flowing eastwards, are the principal rivers; with the exception of one branch-line, the railways are all worked by the Great Eastern Company. The Suffolk crag, or white crag, is one of the divisions of the British Pliocene System (q.v.); and Coprolites (q.v.) are raised in the region between Ipswich and Woodbridge, gun-flints at Brandon. Agriculture, despite the depression of late years, still forms the staple industry, 780,000 acres being under cultivation. A red polled breed of cattle, of which the cows are deservedly held in high esteem, is peculiar to the county; and its pigs, some black and others white, are also widely known. Horse-breeding too, apart from the racing establishments at Newmarket, is a specialty, a large export trade being carried on in both riding and cart horses; and immense quantities of lambs —blackfaced, and a cross between the Norfolk-horned and the Southdown—are raised. The manufactures are noticed under Ipswich (the capital), Beccles, Stowmarket, and Sudbury, these being, with Bury St Edmunds, Lowestoft, and Woodbridge, the most important towns. Containing 21 hundreds and 517 civil parishes in the dioceses of Norwich and Ely, its parliamentary divisions are five in number, each returning one member, and it has two county councils, one for the eastern and the other for the western district. The assizes are held alternately at Ipswich and Bury St Edmunds.

The history of Suffolk, presumably from its lying somewhat off the beaten track, presents but few facts deserving of special mention; prior to the Conquest it was in common with the rest of East Anglia (of which it formed part) ofttimes overrun and pillaged by the Norsemen, whilst of incidents of later date it will suffice to mention the descent of Flemish mercenaries under the Earl of Leicester in 1173 in support of the claims of Henry II.'s eldest son, culminating in their defeat at Fornham, near Bury St Edmunds; and the sea-fights off Lowestoft (1665) and Southwold (1671). In antiquities the county is especially rich, and amongst them may be noted the ruins of the castles of Burgh (Roman), Framlingham, Orford, and Wingfield (the last the place of Charles d'Orleans' imprisonment); the gatehouse of Butley Priory (Norman); earthworks at Fornham, Haughley, Nacton, and Snape; the fine flint-work churches scattered throughout the county, of which perhaps the best examples are those of Blythburgh, Lavenham, Melford, Southwold, Stoke-by-Nayland, and Walberswick; and the old halls (many of them moated) of Helmingham, Parham, Hengrave, Rushbrooke, Ickworth, Somerleyton, Giffords, and West Stow. Of Suffolk worthies (exclusive of those named under Ipswich and Bury St Edmunds) the best known are Bishops Grosseteste, Aungerville, and Bale; Archbishop Sancroft; Chief-justices Glanvill and Cavendish; George Cavendish (Wolsey's biographer); Nash, Crabbe, and Robert Bloomfield (poets); Sir Simonds D'Ewes; the Earl of Arlington, Roger North, Capell (the Shakespeare commentator); Gainsborough, Frost, Constable, and Bright (artists); Bunbury (the caricaturist), Edwards (the etcher), Woolner (the sculptor), Lord Chancellor Thurlow, Arthur Young, Clara Reeve, Mrs Inchbald, Kirby (the naturalist), John Hookham Frere, Crabb Robinson, Sir Philip Broke, William Johnson Fox, Professor John Austin and his brother Charles, Admirals Fitzroy and Rous, Dr Routh, Professors Maurice and Cowell, Edward Fitzgerald, Sir J. D. Hooker, Sir Henry Thompson, Agnes Strickland, and Miss Betham Edwards.

Suffragan (Lat., 'assistant'), in England a coadjutor-bishop appointed to assist a bishop in the administration of some part of his see: such bishops cannot succeed to the see in which they have been suffragans. The name also, and originally, belongs to all bishops in a province, as expressing their relation of subordination to the metropolitan.

Suffrage. See PARLIAMENT, REFORM.

Suffren. Pierre André de Suffren Saint-Tropès, a French naval hero, was born a younger son of a good Provence family, July 17, 1729. At fourteen he entered the navy, and first saw fire in the indecisive action with the English off Toulon in 1744. He took part in the unsuccessful attempt to recapture Cape Breton (1746), was captured by Hawke in the Bay of Biscay the next year, but soon exchanged, and after the peace went to Malta and served for six years amongst the Knights Hospitallers. Again in the French service, he took part in the action off Minorca (May 1756), was again captured in Boscawen's destruction of the Toulon fleet (1759), after the peace of 1763 cruised in the Mediterranean for the protection of trade, and took part in the bombardment of Sallee in 1765. Commander in 1767, he served four years in the service of Malta, and returned to France to the rank of captain in 1772. Early in 1777 he sailed to America, and his ship began the indecisive battle of Grenada on 6th July 1779. He next served with the allied fleet blockading Gibraltar, and early in 1781 was placed in command of a squadron of five ships for service in the East Indies. After an action at the Cape Verd Islands, he outsailed Commodore Johnstone to the Cape, and so saved the colony for the time. Sailing to Madras, he fought a hard but indecisive battle off Sadras, and soon after, in a bloody two days' battle off Providien on the coast of Ceylon, proved himself a consummate master of naval tactics. But he had to struggle against scurvy, want of supplies, and, still worse, the disaffection and cowardice of his senior officers. Having captured Trincomalee, he two days later stood out of the harbour with fifteen ships against the English twelve, and fought a hard but irregular battle. His last fight (June 1783) was also indecisive. Suffren arrived in Paris early in 1784, and was received with the greatest honours, and created vice-admiral of France. He died suddenly at Paris, 8th December 1788, most probably of apoplexy, to which his extreme corpulence made him subject. Frenchmen give the Bailli de Suffren (he had been made Bailli of the Order of Malta) the most exaggerated praises, and Professor Laughton styles him 'one of the most dangerous enemies the English fleets have ever met, and without exception the most illustrious officer that has ever held command in the French navy.' See Laughton's *Studies in Naval History* (1887).

Sufism, a form of mysticism within Islam. The Koran is unfavourable to mysticism, for it tells of a God perfectly distinct from the world and from the souls of men, who has decreed from all eternity the lot of every person, and who is to be pleased with outward rites and conduct. Sufic mysticism has come into Islam through Persia, where, under the influence of Indian Buddhism, its pantheistic ideas existed before the Mohammedan conquest. Sûfîs claim as their founder the woman Râbia, whose grave on a hill east from Jerusalem drew many pilgrims in the middle ages. But that distinction rather belongs to Abû Saîd ibn Abî-l-Chair, a Persian of Khorassan, who, notwithstanding the saying of Mohammed that there is no monkery in Islam, founded a monastery about 815. His followers were called Sûfîs or Woollers from their ascetic garb. A contemplative life soon naturally sought in Pantheism that rest for the heart which it could not find in the distant, unsympathetic God of Islam. Thereafter Sufism divided itself. Some with the Persian Bestâmí, who died in 875, professed openly that man is God. Others with Jonaid, who died in 909, a Persian too, though born in Bagdad, were of like faith, but cautious and orthodox in their language. The favourite watchword of Islam, the Unity of God, meant with them that God is all. The object of all Sufism was to deliver the soul from the sway of the passions by destroying human nature and the power of the flesh, and so to make the soul merely spiritual, uniting it by love with God, from whom it had emanated as a ray emanates from the sun. Cautious Sûfîs were often revered as saints, while sometimes the incautious became martyrs. Many, like Jonaid's pupil Hallâj, who was executed by Hâmid, the vizier of the calif Al-Môqtadir at Bagdad in 922, were alternately adored and persecuted. In Sufism the devotee must choose a teacher, and strive toward development through degrees, of which there are commonly reckoned three. First is the Law, wherein the Sûfî is merely a Muslim, blameless in all ordinances of morality and of Islam; but the only motive to worship or obedience is not fear of punishment nor hope of reward, but love. Second is the Way or Method, wherein he practises asceticism, fasts, watches in silence and solitude, studies Sufistic lore, drives away other thought, rises into an occasional ecstatic state, Hâl, which when permanent is called a position, Makâm. Positive religion, needful for the weak, is now needless for him. The final degree is Certainty; the transcendental objective God has now become subjective; the Sûfî is now consciously God; all religion is vain. The first great Sûfî poet was the Persian Ferîd eddîn Attar, who died *c.* 1220. The greatest Sûfî poet was another Persian, Jelâl eddîn Rûmî (1207–73). But Sufism, the dream of the least and the most cultured alike, has been the religion of Hâfiz and Sâdi and of nearly all the great Persian poets. Their luscious language of love and beauty's charms, of intoxication and the wine-house, is strongly sensual or spiritual according as it is taken. Of the Safides, who reigned over Persia from 1499 to 1736, the first was Ismael the Sûfî. In 1777 a famous Sûfî, Mîr Maçûm Ali Shah, came from India to Shirâz, and raised a great Sûfî fervour, against which a very severe persecution was started by church and state in 1782, and lasted many years. Yet the influence of Sufism in Persia and eastward is rather increasing than waning; and in all orthodox lands this most fatal dissolvent of Islam is welcomed. There are many sects in Sufism. In Persia when the 19th century began there were at least a quarter of a million of Sûfîs. There are more now; but with the majority the name means not pantheist but freethinker. In this sense the Sûfîs or Wise may include half of the Persian middle class.

Sugar. The sugars form a natural group of substances, for the most part of vegetable origin, connected with glycerol and the glycols on the one side and with the dextrins and with bodies of the starchy class on the other. They are, as a rule, crystallisable, soluble in water, less soluble or insoluble in alcohol, and insoluble in ether and in other solvents which are immiscible with water; they have a sweet taste, a physical characteristic varying in the several members of the group from the luscious sweetness of cane-sugar to the feeble sweetness of some of the saccharoids. This quality, however, is not confined to the sugars, being also possessed by the glycols, by glycerol, by glycocine, by certain compounds of the aromatic group, and even by some inorganic salts, such as those of lead and yttrium. Most sugars possess the property of causing rotation of a ray of polarised light, and this optical activity serves as a means of estimation of very great value to the analyst. The sugars are divided according to the views entertained as to their constitution into three classes: the *saccharoids*, the *glucoses*, and the *saccharoses*. The *saccharoids* are regarded as saturated hexatomic alcohols, and have the general formula $C_6H_{14}O_6$, or differ from this in having in certain instances the elements of water superadded. Mannite, dulcite, isodulcite, hesperidin sugar, persite, sorbite are the chief saccharoids, but quercite, pinite, raffinose, and erythro-mannite, which possess formulæ departing from the type $C_6H_{14}O_6$, are usually included under the same heading. The saccharoids are all crystalline, and not capable of being fermented either with yeast or with the lactic and butyric bacteria, or in one or two instances undergo a very feeble action of this kind. The *glucoses* are more important; they are the aldehydes of hexatomic alcohols, and have the general formula $C_6H_{12}O_6$. Dextrose, lævulose, and mannitose closely resemble one another, reduce Fehling's solution, readily ferment (except the last) with yeast, rotate the plane of polarisation, and when oxidised yield saccharic acid. Galactose, which is probably a mixture of two dextro-rotatory sugars, closely resembles lævulose, but has a feebler action on Fehling's solution, and yields mucic acid under the influence of oxidants. Inosite, sorbinose, and eucalyptose do not ferment with yeast, but are acted upon by the lactic and butyric bacteria (chalk and cheese).

Copyright 1802 in U.S by J. B. Lippincott Company.

Dextrose (synonyms glucose, grape-sugar, starch-sugar) is the most important sugar of the glucose class. It occurs in the anhydrous condition as transparent prismatic crystals, and in warty masses having the composition $C_6H_{12}O_6 + H_2O$, which lose all their water below 100° C. It melts at 146° C., is less soluble in water and in alcohol than sucrose, and dissolves in boiling water in all proportions. Dextrose has a dextro-rotatory action upon polarised light, and reduces Fehling's solution. It is not affected by moderate boiling with dilute acids, nor does it readily char under the influence of strong sulphuric acid, but forms with this body an acid ethereal salt decomposed by water. It also forms analogous compounds with many other acids. It is rapidly decomposed on boiling with caustic alkalis or caustic lime. Dextrose is found ready formed in the grape to the extent of 15 per cent., and in many other fruits. It may be prepared by decomposing the glucosides and by the hydrolysis of starch, dextrin, cane-sugar, &c., by means of dilute acids, diastase, or invertase, also by the action of sulphuric acid upon cellulose. In honey and in many fruits it occurs in association with lævulose, a glucose which bears a great resemblance to it, but is distinguished by having a greater sweetness and a lævo-rotatory power. Lævulose is said to be even sweeter than cane-sugar.

The *saccharoses*, with the general formula $C_{12}H_{22}O_{11}$, are the most important sugars, inasmuch as ordinary sugar, malt-sugar, and sugar of milk are members of this class. They may be regarded as condensation products of the glucoses, and derived from two molecules by elimination of the elements of water, thus: $2C_8H_{12}O_6 - H_2O = C_{12}H_{22}O_{11}$. The saccharoses are, with the exceptions of malt-sugar (maltose) and milk-sugar (lactose), incapable of reducing Fehling's solution. They are fermented by yeast, but only after previous conversion into glucoses by the agency of an enzyme (or enzymes), invertase, secreted by that organism. The saccharoses are charred by strong sulphuric acid. Besides the three already mentioned, this group contains melitose, melezitose, mycose, and synanthrose.

Sucrose (syn. cane-sugar, saccharose, saccharon, cannose, &c.) is a solid crystallising in the form of monoclinic prisms—generally with hemihedral faces—which are transparent, colourless, and have a sweet taste, a specific gravity of about 1·6, a melting-point of about 160° C., and strongly rotate the plane of polarisation to the right (see below). Sucrose is soluble *in about half its weight of cold* water and in boiling water in all proportions; it is nearly insoluble in absolute alcohol and soluble in dilute alcohol, the solubility increasing with the dilution in an ascending ratio. Ether, chloroform, carbon disulphide, oil of turpentine, petroleum spirit, and liquids immiscible with water generally, have no solvent action upon this sugar. Sucrose melts at about 160° C. (320° F.), and assumes on cooling the condition known as 'barley-sugar,' which is probably an allotropic form; at a little above the fusing-point it passes into a mixture of dextrose and lævulosan without loss of water. When still further heated water is given off, and the mass begins to blacken with evolution of fumes having a characteristic odour; and at about 200° C. caramel, a mixture of caramelan, $C_{12}H_{18}O_9$, caramelen, $C_{36}H_{50}O_{25}$, and caramelin, $C_{96}H_{102}O_{51}$, is obtained. Caramel is largely used for the colouring of wines, beer, vinegar, &c. Alkaline hydroxides in the cold have little or no action on sucrose, but when fused with caustic potash this sugar yields oxalate and acetate of potassium.

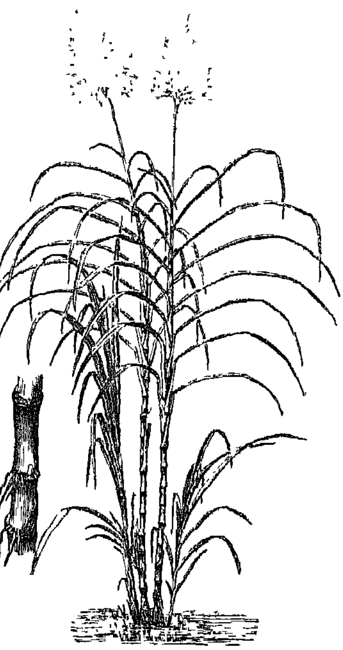
Solutions of sucrose possess the property of dissolving the oxides of the alkaline earths, with which the sugar forms compounds of definite composition. The *Liquor Calcis Saccharatus* of pharmacy is a solution of lime in syrup, and with baryta sucrose forms the compound $C_{12}H_{21}(BaOH)O_{11}$, which falls as a precipitate when syrup is mixed with a concentrated solution of barium hydroxide. With strontia sucrose forms the compound $C_{12}H_{20}(SrOH)_2O_{11}$ as a precipitate, and this reaction is employed commercially for the separation of crystallisable sugar from molasses. The precipitate is granular, easily separates, and after being washed with hot water is decomposed with carbonic acid.

Sucrose in the solid condition, or in the form of a strong syrup, is decomposed in the cold by concentrated sulphuric acid, with formation of a spongy carbonaceous mass, and evolution of sulphur dioxide and other volatile products. Nitric acid acts upon sucrose, forming nitrosucrose, saccharic acid, oxalic acid, or carbonic acid, according to the concentration of the nitric acid; the fuming acid in the cold produces nitrosucrose. Sucrose, like all the members of the saccharose group, is hydrolysed when heated in solution with dilute acids; in the case of sucrose a mixture of dextrose and lævulose results, the change consisting in the assimilation of the elements of water and bisection of the sucrose molecule. This action is termed 'inversion,' because the solution after the action of the acid rotates the plane of polarisation to the left, but the term is now applied generally to the hydrolysis of saccharoses by acid. Inversion takes place slowly even in the cold with hydrochloric or sulphuric acid, and with dilute solutions of sucrose, but at 70° C. the change is very rapid; acetic, tartaric, citric, and the other weak acids have much less power in this respect. The process of inversion is of value in analysis of mixtures of various sugars.

Sucrose is a strong reducing agent, which is another way of saying that it is readily oxidised. It quickly decolorises solutions of potassium permanganate even in the cold, and on boiling with this reagent yields oxalic and carbonic acids. When heated with solutions of silver or mercury it causes separation of the metals, and it precipitates gold from the chloride. When boiled with cupric salts in presence of alkaline hydroxides there is no separation of cuprous oxide, but after continued ebullition a partial reaction occurs. After undergoing inversion by dilute acids or invertase it quickly and completely reduces alkaline solutions of copper (see below).

The behaviour of sugar under the influence of *living ferments* is of great interest theoretically, and of importance from a practical point of view. Some of the mould fungi (Hyphomycetes), nearly all the yeasts (Saccharomycetes), and many torula forms ferment solutions of sugar with formation of alcohol and carbonic acid in presence of some forms of albumenoid matter, and of certain inorganic substances. The mould fungi, particularly those of the genus Mucor, function as alcoholic ferments, that property being especially but not exclusively possessed by the budding spores of these organisms, which in many instances closely resemble the yeasts in appearance. The commonly occurring mould *Penicillium glaucum* possesses the power of secreting an invertive ferment which is able to convert sucrose into other sugars. *Monilia candida* directly ferments solutions of this sugar without previous inversion, a property not possessed by the strong yeasts; *Mucor racemosus* secretes invertase and ferments sucrose after inversion; several other Mucors, as *M. erectus*, *M. spinosus*, *M. mucedo*, *M. circinelloides*, &c., have no inverting action, but can produce fermentation after the sugar has been inverted by extraneous means. But the chief interest attaches to the action of yeasts, which are *par excellence* the true alcoholic ferments. The strong yeasts, *Saccharomyces cerevisiæ* (both top and bottom forms), the two forms of *S. ellipsoideus* (bottom forms), and the three forms of *S. pastorianus*, all secrete invertase and vigorously ferment sucrose. Of the feeble yeasts *S. marxianus* and *S. exiguus* (Hansen), which have little action on maltose, invert sucrose and ferment it with energy. Of the other species of Saccharomyces in some instances little is known regarding their fermentative action; but *S. membranæfaciens* is believed to be the only Saccharomyces which neither inverts nor incites fermentation of one kind or another. *S. apiculatus* (so called, although not a true Saccharomyces because it forms no gonidia) secretes no invertase, and therefore cannot act upon sucrose. The action even of the stronger yeasts upon this saccharose is very feeble in the absence of albumenoids of the peptone class and of the necessary salts, but in the presence of these latter ammonium compounds, asparagin, and some other nitrogenous bodies can to a great extent supply the place of the albumenoids. Under favourable conditions—viz. the presence of these necessary yeast foods and of sucrose to an extent not too great—the introduction of a small quantity of healthy yeast is quickly followed by the multiplication of the organism, accompanied by inversion of the sugar and the production of alcohol and carbonic acid. The process of inversion takes place at an early stage of the fermentation, and is a chemical reaction capable of being effected by the enzyme (invertase), separately presented in the absence of the organism; the production of alcohol is a function of the living cell, and becomes slower and more difficult as the percentage of spirit increases, the alcohol constantly tending to inhibit the fermentative act, until at length, when about 14 per cent. of alcohol has been produced, it ceases altogether. Pasteur, who was the first to show the true character of yeast, formerly considered the fermentation of sugar to be an anaërobic phenomenon, taking place only in the absence of oxygen, in order to obtain which the yeast tears up the sugar molecule; this view, however, is not now held, it being believed that the Saccharomycetes are to a great extent indifferent in this respect, playing their part equally well in presence of much oxygen or of a minute (necessary) quantity. Besides alcohol and carbonic acid other substances are produced from sucrose by yeast, notably glycerol and lactic acid, and certain odorous principles to a small extent. Pure cultures of yeast are said not to elaborate the higher alcohols (fusel-oil), but this view requires to be supported by further investigation.

Sucrose occurs very widely in the vegetable kingdom. It is found in the sugar-cane (*Saccharum officinarum*), of which a number of varieties are known and cultivated; in many other grasses (Gramineæ); in the sap of many forest trees; in the roots of certain plants; in numerous seeds; in most sweet fruits, usually in association with invert sugar; and in the nectar of flowers. The sugar-cane was the source from which sugar was originally prepared, and the East first learned the use of this article of diet. The cane has doubtless been known in India from time immemorial, and sugar is still produced from this source in that country, but the quality of that now exported does not bear comparison with the product of other lands. The early classical writers, especially Herodotus, Theophrastus, Seneca, and Strabo, make undoubted references to sugar, which they speak of as 'honey of canes,' or 'honey made by human hands;' and at about the date of the Christian era this substance had become pretty generally known under the name of *saccharon* or *saccharum*. Our word sugar is derived, through Fr. *sucre*, Span. *azucar*, Arabic *sakkar*, Persian *shakar*, from the Sanskrit *sharkará*, which signifies a substance consisting of small grains. The term candy, applied to sugar in large crystals, took its origin from the Arabic and Persian *kand* or *kandat*. It is believed that Bengal was the locality in which cane-sugar in a dry granular state was first prepared. The Chinese admit that they first gained their knowledge of the art of making sugar from India, somewhere about 766 to 780 B.C. We have evidence that at a later period, the 9th century of our era, sugar was grown in Persia, and the Persian physicians of the 10th and 11th centuries first introduced it into medicine. The Arabs cultivated the cane in many of their Mediterranean settlements, and as early as 961 A.D. the plant flourished in the Iberian peninsula. Soon afterwards sugar of Egyptian origin formed a staple of trade between the merchants of Venice and of London, wool, which then constituted the great wealth of England, being largely exported in exchange for it. The manufacture of sugar from the cane, thus interesting historically, still furnishes a considerable part of the entire supply; and the best sugar is derived from this source, although the beet-root now actually yields a greater quantity.



Sugar-cane (*Saccharum officinarum*).

The sugar-cane has been introduced into almost all tropical and subtropical countries; the East and West Indies, the southern United States, Central America, Brazil, Peru, Chili, Mauritius, the Malayan Archipelago, Egypt, northern Australia, South Africa, and many islands of the Pacific may be mentioned as illustrating the wideness of its range, although the list is by no means exhaustive. The cane seems to have been introduced by Jesuits into the southern United States from the West Indies about 1750; but sugar culture was neither an important nor prosperous industry when Louisiana was ceded to the United States in 1803. This state soon became and still is a great sugar-producing state; the cane is grown in all the Gulf states on both sides of the Mississippi (though in all these states it sometimes suffers from frost). In Europe it is or has been grown a little in Sicily and in Andalusia.

The cane, which may be described as a gigantic grass, thrives best in a warm, moist climate, with prevalent sea-breezes and moderate intervals of hot, dry weather. Many descriptions of cane exist, and these are regarded as varieties of one species, although some botanists have raised a few to the rank of distinct species. The common sugar-cane of the United States is the Creole or Madeira; others cultivated being the Otaheite, Batavian, Chinese, and Salangore. The stem, which varies from 6 to 14 feet in height, is from 1 to 1½ inch thick, and jointed at intervals of from 3 to 6 inches; its pith, of open cellular structure, contains the sugary juice. The tops and lower joints are not crushed; the outer skin contains much silica. The 'arrow' or flowering stem is without joints, and bears a panicle of soft, silky flowers. The cane suffers much from the ravages of rats (to check whose ravages the mongoose or ichneumon has in some places been successfully used), from white ants, and several boring insects. The plant is propagated from the eyes or buds which grow on the stems, as no cultivated cane seems to ripen its seed; and the 'stoles,' or portions remaining in the ground, throw up fresh canes, called ratoons, for several seasons—sometimes twenty years—after which replanting is necessary. The young cuttings are planted in rows 3 feet apart, and at intervals of 2 feet from plant to plant. The cane requires a fertile, marly soil, not too heavily charged with common salt or other saline ingredients. The most suitable manure is farmyard dung or night-soil; superphosphates and the various artificial fertilisers are considered to be less advantageous, but the presence of lime is of primary importance.

The sugar exists in a state of solution in certain cells in the stem of the plant, and in order to obtain it several methods are adopted. The juice is sometimes expressed by means of powerful roller-mills which rupture the cells, or the crushing is preceded by maceration in water. Sometimes the diffusion method is adopted, which consists in cutting the canes into short pieces and soaking these in an equal weight of water; several vessels are employed, the liquor from the first being passed into the second, where it becomes more concentrated, and so on throughout the series. Cane-juice, pure and simple, of course contains the highest percentage of sugar, its average composition being as follows: water, 81; sugar, 18; uncrystallisable sugar, 0·4; other organic matter, 0·6; mineral matter, 0·4. To obtain such juice the canes are passed lengthwise through the rollers, usually three in number, which have a combined slow rolling and sliding motion, and great care is taken to prevent doubling up of the canes and consequent stoppage of the mill. So long as the juice is enclosed within the cells of the plant it never enters into fermentation, but when liberated it rapidly undergoes such change, and it is therefore necessary for it to be submitted to the processes of clarification and evaporation without loss of time. Clarification, or defecation, is carried out with lime and chemicals, and may be described in general terms as follows. The juice is raised to a temperature of 80° C. (176° F.), and milk of lime is added in quantity sufficient to neutralise the acid, the liquor then being allowed to stand for the separation of the coagulated impurities, some of which subside while others rise to the surface. Sulphurous acid or its salts are also sometimes used, as well as finings, such as clay, which help to carry down the suspended matter. The clarified juice is next run through bag, charcoal, or capillary filters, and then concentrated. This is effected either in open coppers, by means of film evaporators, or in vacuum-pans. The first method leads to loss of sugar and discoloration of the product, and is becoming obsolete. The second operation may be briefly described as passing the juice in a thin layer over the surface of a cylinder (or 'wetzel') heated internally by steam. The vacuum-pan, for a fuller description of which the student must consult larger works (e.g. Spon's *Encyclopædia of Industrial Arts*), is essentially a spherical copper vessel heated at the bottom by steam-coils, and communicating at the upper extremity by means of a still-head with a powerful air-pump which draws off the vapour as fast as it forms, and thereby maintains the boiling-point of the syrup at about 66° C. (150° F.).

The art of pan-boiling consists in concentrating the syrup until minute grains are formed, and then 'feeding' these by repeated admissions of fresh liquor. The *masse-cuite*, as the thick mass of crystals is termed, is usually submitted to the action of centrifugal machines which separate it into two portions, dry crystals and syrup or molasses.

Sucrose is at the present time prepared more extensively from the beet-root than from the cane, and the article so produced is commonly, but erroneously, called cane-sugar. The beet-sugar industry was first stimulated by Napoleon I., especially during the period when France was deprived of sugar by the English blockade, and has assumed immense proportions owing in great measure to the scientific skill that has been expended upon it. The Beet (q.v., *Beta vulgaris*) is indigenous to Europe, and many varieties of this plant, as of the sugar-cane, are known. The juice of the root contains from 12 to 18 per cent. of crystallisable sugar associated with various salts, such as the phosphates, oxalates, malates, and chlorides of potassium, sodium, and calcium, besides albuminous, pectinous, and other substances. The plant thrives best in a deep, friable 'turnip loam,' neither too stiff nor too light, and manuring with phosphatic manures gives the best results; peaty and moorland soils and farmyard manure are less suitable. The seed is usually sown in April, and the crop gathered in autumn before the incidence of early frosts.

The methods for the extraction of the sugar are in the main analogous with those appertaining to the manufacture of sugar from cane-juice. The roots having been harvested are stored until required for use in pits dug in the ground, and covered with straw and earth for protection from frost. They are afterwards taken out and introduced into vessels called 'washers,' where they are separated from stones and adhering dirt by a rapid current of water. The roots thus cleansed are then treated for the extraction of the sugar either by (1) rasping and pressing, (2) maceration, or (3) diffusion. The first of these methods consists in reducing the roots to a fine pulp by machinery, and subsequently squeezing out the juice by powerful presses, the combination representing the cane-mill of tropical regions. The maceration process is applied to the pulp, which is subjected to the action of water in suitable vessels, the exhausted pulp being afterwards strained from the liquid which now contains the sugar in solution. The diffusion method does not require the rupture of the cells, but utilises the power which sugar and the saline matters, as crystalloids, possess of passing through the unbroken cell-membrane, leaving behind the colloid, albuminous, and pectinous substances. The juice or solution obtained in one or other of these ways is defecated by 'double carbonation,' according to which lime is first introduced in the cold, and afterwards removed by the action of carbonic acid, followed by heating to 90° C. (194° F.), the treatment being subsequently repeated upon the decanted juice this time at a boiling temperature throughout. The liquor is next filtered through animal charcoal for the removal of colouring matter, and of the slight excess of lime still remaining, boiled down to a density of 25° B., again passed over charcoal, and then evaporated to a mass of crystals in a vacuum-pan as in the case of cane-juice.

Sucrose is also made in America from the sugar-maple (*Acer saccharinum*) and the melon (*Cucumis melo*); in America and elsewhere from different varieties of sorghum (see DURRA) and from maize (*Zea mays*); and in various tropical countries from the date-palm and other species of Palmyra. Palm-sugar is derived from the juice which flows from incisions made in the trunk of the tree. This is very pure, containing less non-saccharine matter than cane-juice, and far less than beet-juice, and the sugar is obtained by simple evaporation in open pans. Sorghum-sugar is extracted and fabricated by processes that are almost identical with those employed in making sugar from the cane, but the machinery is usually constructed on a much smaller scale. Maple-sugar is manufactured by simple evaporation in iron or copper pans of the sweet sap draining from auger holes made in the trunk during the months of spring. In 1891 the total production of sugar of all kinds in the United States was estimated at 539,710,000 lb.—500,000,000 lb. from cane, 29,210,000 from beet, 2,500,000 from sorghum, and 8,000,000 from maple sap. The cultivation of sugar beet is making progress under the auspices of the Department of Agriculture.

In former years, before the beet industry assumed its present enormous proportions, and when the cane was the chief source of supply, sugar was to a great extent consumed in the condition in which it arrived from the producing country. This, which was possible and even pleasant with the sweet and fragrant cane muscavadoes, became impossible when raw beet-sugar with its unpleasant vegetable flavours was introduced, and the practice of refining all sugars became established. Sugar-refining is carried out in high buildings, so that the materials may gravitate from higher to lower levels in order to avoid the cost of pumping. The first operation, that of discharging the hogsheads of muscavado, bags of beet, mats of jaggery (as most of the sugar from the East is called), or other packages, takes place on the highest floor of the refinery. Here the sugars are mixed, and thence delivered on to the next lower or 'blow-up' floor by means of shoots. The 'blow-ups' are large vessels in which the sugar is dissolved in hot water to a syrup of 25°—27° B. when hot, equal to 27°—30° B. when cold. The syrup next flows through filter-bags, of which a large number are required, owing to the slimy nature of the suspended matter, and is then caused to gravitate down large iron cylinders packed with granulated animal charcoal. This is produced by heating bones to redness in closed vessels without access of air, and possesses the power of removing colouring (and other) matters not only from sugar solutions, but from most organic liquids. After a time the charcoal becomes spent and ceases to act, but regains its properties upon reburning, an operation which is carried out in a refinery as many as a hundred times. The first syrup running from the char-cisterns is quite colourless, and this portion is collected apart and boiled for the production of loaves or crystals. The last portions of syrup yield the 'pieces' or yellow moist sugar. The boiling is effected in vacuum-pans, and a small quantity of sulphurous acid is added to the pan and greatly improves the colour of the 'pieces.' In boiling this class of goods the object is to form a 'false grain'—i.e. an aggregation of small grains having the appearance of larger particles; in this way a soft-looking sugar of primrose complexion and carrying a large quantity of syrup, which pleases the eye much more than a gray-looking 'piece' sugar of bolder grain, is obtained. The thick mass from the pan is discharged through an opening in the bottom into centrifugal machines, which, with the aid of a little wash water, separate the crystals from the syrup. This operation of 'machining,' it should be mentioned, is frequently applied to hard grainy beet-sugars in the initial stage of refining, and the resulting ill-smelling impure syrup treated apart from the grayish white and comparatively pure crystals left upon the machine.

Lump sugar is made by draining a very stiff masse-cuite of small grain in moulds, and afterwards drying the concreted loaves; for the production of cube sugar moulds of peculiar shape are used, which when filled are placed in centrifugal machines to facilitate the removal of the syrup.

Analysis.—Three estimations are chiefly necessary for the analysis of raw sugar, the determination of polarising value, of glucose, and of ash or mineral matter. The polarimeter is an instrument by which the rotatory power of sucrose (or other sugars) upon a ray of polarised light is made available for purposes of quantitative measurement. Those instruments are the best that require the use of the yellow light of the sodium ray. The two Nichol prisms of the polarimeter being crossed and the vernier at zero, a filtered solution of sugar containing a known weight of the sample in unit volume is introduced into a tube 20 centimetres long and placed between the prisms. The result is a transmission of light requiring for its suppression the rotation of the analysing prism, the one nearest to the eye. From the angular degrees of this rotation the polarising value of the sample is deduced.

In actual instruments an ingenious device is made use of for the sake of gaining delicacy. This consists in covering one-half of the optical field with a half-wave plate of quartz, or, in the modern instrument made by Field & Co. of Birmingham, by a less expensive but equally efficacious half-wave plate of mica; the field in these instruments is always more or less bright, but the slightest movement of the prism in either direction from the neutral point causes an unequal shadowing of the two semi-discs, and very sharp observations can be made. The presence of glucose in sugar, and the amount, are ascertained by *titration* with standard Fehling's solution made by dissolving in every litre 34·64 grams of crys. sulphate of copper, 70 grams of caustic soda, and 180 grams of Rochelle salt. This liquid is not affected by sucrose, but when a solution of a sample containing glucose (also maltose, lactose, &c.) is delivered into a known volume of the copper solution diluted with water, and kept at the temperature of boiling, the copper is precipitated as red suboxide, and the supernatant liquid becomes colourless. The volume of the solution of sugar required to effect this result is a measure of the glucose present. The ash of sugar is ascertained by burning 1 gram of the sample in a platinum capsule at a red heat; but, owing to the difficulty of obtaining a white ash from the fusible salts, it is usual in technical practice to add two or three drops of strong sulphuric acid before ignition, and to deduct one-tenth for the extra weight thus introduced. From the various determinations made as described the *rendement* or refining value of the sample is deduced by subtracting five times the percentage of ash plus the percentage of glucose from the percentage of sucrose indicated by the polarimeter; in the case of sugar from the cane only three times the ash is deducted by some analysts.

Besides sucrose the only saccharoses of practical importance are lactose and maltose. Lactose is the natural sugar of milk. It is a solid substance of sweetness inferior to sucrose, crystallising in hard, white, semi-transparent masses, having the composition $C_{12}H_{22}O_{11} + H_2O$, and soluble in water, but unsoluble in alcohol or ether. When boiled with dilute sulphuric or hydrochloric acid it is converted into the two glucoses dextrose and galactose. It is not fermented by yeast alone, but in contact with yeast and putrefying casein it ferments, yielding alcohol and lactic acid. Koumiss is a product of such fermentation acting upon the milk of mares. Lactose reduces Fehling's solution and rotates the plane of polarisation to the right.

Maltose, $C_{12}H_{22}O_{11}$, occurs in fine crystalline needles, soluble in water and in alcohol, but to a less extent than sucrose. This sugar reduces Fehling's solution, and has a dextro-rotatory polarisation. It derives its chief interest and importance from the fact that it is the principal ingredient in beer worts, in which it owes its presence to the action of an enzyme, diastase, possessing the power of hydrolysing starch, and forming from it maltose and dextrin, but not glucose, as was formerly supposed. It is probably not directly fermentable by yeast, but is rapidly inverted by that organism and converted into alcohol and carbonic acid.

The world's production and consumpt of sugar—especially beet-sugar—has increased largely within recent years. In an average year of the period 1853-55 the total was estimated, in papers published by the British Board of Trade in 1889, at 1,423,000 tons; in 1871-73, at 2,786,000; in 1886-87, at 5,187,000. In the same years beet-sugar production was respectively 190,000 tons, 1,042,000 tons, and 2,433,000 tons; cane-sugar from British colonies, 261,000 tons, 336,000 tons, 580,000 tons; foreign cane-sugar, 972,000 tons, 1,408,000 tons, 2,174,000 tons. Of the total supply the United States is believed to consume 29 per cent., and the United Kingdom 21 per cent. The sugar-refining industry of Britain (as in Greenock, q.v.) has suffered much from the Bounties (q.v.) given by sugar-producing countries and foreign tariff legislation. In 1872 Great Britain imported 5,139,509 cwt. of raw cane-sugar from British possessions, 6,677,557 cwt. from foreign countries, and 1,959,630 cwt. from beet-growing countries; in 1882, 5,567,175 cwt., 8,967,695 cwt., and 5,304,355 cwt. respectively; and in 1888, 3,446,949 cwt., 8,039,103 cwt., and 6,371,417 cwt. The total imports of refined sugar meanwhile increased from 15,505,998 cwt. in 1872 (1,719,946 of beet-sugar) to 24,729,423 cwt. in 1888 (6,830,274 of beet-sugar). In 1872 the United States raised 146,906,125 lb. of sugar at home, imported 1,509,185,674 lb., and exported 16,958,822 lb. In 1889 it raised 337,933,124 lb., imported 2,762,202,967 lb., and exported 19,751,597 lb. Much sugar is used by brewers. The cost of sugar has sunk since about 1850 from 7d. or 8d. per lb. to 2d. In 1892 the sugar-refining industry of the United States passed almost wholly into the hands of one syndicate with a capital of $85,000,000.

Soames, *Manufacture of Sugar* (1872); Lock, Wigner, and Harland, *Sugar Growing* (2d ed. 1885); Ware, *Sugar Beet* (1880); M'Murtrie, *Report on the Culture of Sugar Beet* (1881); Lock and Newlands, *Sugar: Handbook for Planters and Refiners* (1889); F. G. Wiechmann, *Sugar Analysis for Refineries* (1891); H. L. Roth, *Guide to the Literature of Sugar* (1890); also the exhaustive article in Spon's *Encyclopædia of the Industrial Arts*, with full bibliography. For the chemistry and analysis of sugar, see Allen's *Commercial Organic Analysis* (1879; new ed. 1889), or Prescott's *Organic Analysis* (New York, 1888). For legislation, see Boizard and Tardieu, *Histoire de la Législation des Sucres, 1664-1891*. See also the article SACCHARIN.

Sugar of Lead. See LEAD, Vol. VI. p. 543.

Suhl, a town of Prussia, standing in a romantic valley on the south-west side of the Thuringian Forest, 32 miles by rail SW. of Erfurt. It has long been celebrated for its manufacture of firearms, both military and sporting, and from the middle ages down to the 18th century was no less celebrated for its swords and war-armour. There are also iron and machine works, potteries, and tanneries. Pop. 10,602.

Suhm, PETER FREDERIK (1728-98), a Danish historian, was born and died at Copenhagen.

Suicide (a word coined in England on a French model, but of Latin elements), according to English law, is a Felony (q.v.). A person found *felo de se* (guilty of self-murder) by a coroner's jury was formerly buried at a cross-road with a stake driven through his body, but this barbarous practice (a survival probably of the vampire superstition) was abolished in 1823. A person is *felo de se* if he commits any felonious act which results in his own death; a person who shoots at another with a gun which bursts and kills himself, a woman who dies of poison taken to procure miscarriage are both guilty of self-murder. If two agree to assist one another in committing suicide, and one survives, he is guilty of murder. Policies of life insurance are usually so framed as to be void if the insured dies by his own act, whether he is of sound mind or not. In Scotland suicide involves 'single escheat'—i.e. forfeiture of the movable estate of the deceased to the crown; but this rule does not apply in cases of insanity. In the United States the constitutions of eleven states provide that the property of suicides is not to be forfeited.

The question as to the moral justification of suicide has exercised the minds of ethical philosophers from the days of Plato, Marcus Aurelius, and Seneca down to the present time. Some schools of thought, notably Stoics and their adversaries the Epicureans, defended suicide under proper conditions; Christianity has always refused to admit any justification for self-destruction, and the Roman and Anglican churches deprive of ecclesiastical burial those who have without doubt wilfully committed self-murder.

From the medical point of view suicide is in the majority of cases a symptom of disease of the brain. It is not now denied, however, by any competent medical authority that sane men may and do commit suicide; and then the attempt is unquestionably a crime deserving of punishment. The brain constitution of some persons is such that when they are under the immediate influence of alcohol they always become suicidal. The next kind of case in which suicide is attempted is one on the borderland of disease. It is the man intellectually sound and not emotionally depressed who simply loses for the time his primary instinct of the normal love of life, ceases to have any fear of death, and suffers from the *tædium vitæ* of the ancients, and who in this state, for trivial causes or for no outward cause at all, attempts his life. Some such men are in Hamlet's frame of mind: 'To be or not to be? That is the question.' A man in this state, which is often a hereditary one, cannot always be reckoned insane, and yet he is in an abnormal state of brain and mind. The mass of suicides, however, are committed or attempted by persons who are either insane or on the verge of insanity, though as yet we cannot tell the percentage of sane and insane suicides. The two forms of insanity in which suicidal impulses are most frequent are melancholia and alcoholic insanity. Four-fifths of all patients suffering from melancholia have suicidal feelings, and two-fifths of them make actual attempts on their lives. It is a risk that should be considered and provided against in every case of melancholia and in every case beginning to suffer from alcoholism or alcoholic insanity. The love of life, with efforts to preserve it, is the primary and strongest instinct not only in man, but in all the animal kingdom, without which all animated creation would soon come to an end. The loss of this is the most striking change that can possibly take place in the higher faculties or functions of the brain. The tendency to suicide is very hereditary. Suicide may be carefully contrived and planned for months, or it may be done through a momentary morbid impulse. It may be done, and commonly is done, from insane delusions, such as that the patient is going to be killed and tortured, that he is going to be tried, that his food is poisoned, that he is too great a sinner to live and must make expiation, that he is the cause of evil to all around him, that he cannot recover, &c. Physicians especially guard against suicide with patients who are very much afraid they are to be put to death, and who therefore might be supposed to be too much afraid of dying to do any harm to themselves. Prolonged sleeplessness will sometimes lead to suicidal feelings through brain exhaustion. Suicidal feelings are sometimes the very first symptom of insanity, before anything mentally wrong is suspected and before any watching or precautions are therefore taken. Attempts at suicide are sometimes made while the patient is quite unconscious or in a state of altered consciousness, so that there is no recollection of it afterwards. Sometimes it is suggested by the sight of a weapon or water or any such means of destroying life. When the suicidal desire is strongly present it is a mistake to suppose that the patient's former religious sentiments, or his sense of duty, or his obligations to those dependent on him, or any other rational motive can be depended upon to prevent his committing the act.

The modes of committing suicide vary in different countries, in the two sexes, and in different professions. Hanging is the favourite method in most European countries, except Italy, where drowning and shooting are most common. Suicide is much more common among men than among women, being in the proportion of 3 or 4 to 1; and this applies to all countries and races. As to age, 'suicide augments in the two sexes in direct ratio with age,' at least up to the seventieth year; there are instances of suicide at five years of age, and also over ninety. The critical periods of life, adolescence, the climacteric, pregnancy, parturition, nursing, and senility all increase the tendency to suicide, just as they increase the tendency to insanity. Suicide in all civilised countries is becoming more common year by year. The solitary system in prisons is found to increase the number of suicides as compared with the older system of associating prisoners together. Physical diseases, notably those that are very painful and those that are slow and chronic, increase the number of suicides. The increased consumption of alcohol, especially spirits, increases the suicides of any country, they having doubled from this cause in France from 1849 to 1876. The religion of a people seems to exercise a marked influence on the number of suicides. In states where the Roman Catholic form of religion prevails there are 58 suicides per million of the population; in Protestant states there are 190 per million, and in countries where the Greek Church is dominant only 40 per million. But the social circumstances of each country need to be taken into consideration to correct in some degree the conclusions derived from such religious statistics, the Protestant states being on the whole the most advancing and the most modern in spirit, and a higher standard of general culture being always accompanied by a larger number of suicides. No doubt it takes a highly developed brain that has been cultured to feel keenly, and keen feeling is the basis of painful emotion. Suicide is most common among the widowed and least frequent among the married. The military profession furnishes much the largest proportion of suicides in all countries, being usually twice or thrice that of any other calling, and in Italy fourteen times larger than the average; next comes domestic service; next come the liberal professions. 'The proportion of suicides in all Europe is greater among the condensed population of urban centres than amongst the more scattered inhabitants of the country' (Morselli). But the proportion is not precisely according to the density of population. Denmark stands highest in Europe (285 per million of population), Germany, north and south, next (from 150 to 165), Norway and Sweden next (128), Great Britain, her colonies, and the United States at 70 per million.

Amongst notable suicides (omitting cases referred to in Scripture) may be mentioned:

Sappho	B.C. 7th c.
Empedocles (q.v.)	435
Demosthenes	322
Hannibal	183
Mithridates	63
Cato the Younger	46
Brutus and Cassius	42
Mark Antony	30
Cleopatra	30
Nero	A.D. 68
Otho	69
Maitland of Lethington	1573
Sir John Suckling (?)	1642
Robert Burton (?)	1649
Vatel the cook	1671
Earl of Essex	1683
Blount the Deist	1693
Eustace Budgell	1737
Chatterton	1770
Clive	1774
Rousseau (?)	1778
M. Roland	1793
Pichegru	1804
Tannahill	1810
Berthier	1815
Romilly	1818
Castlereagh	1822
Haydon	1846
Hugh Miller	1856
Admiral Fitzroy	1865
Prévost-Paradol	1870
E. M. Ward, painter	1879
Fred. Archer	1886
Louis II. of Bavaria	1886
Crown-prince of Austria	1889
Pigott	1889
Balmaceda	1891
Boulanger	1891

See Forbes Winslow, *The Anatomy of Suicide* (1840); French works by De Boismont, Bertrand, Mme. de Stael, Legoyt (1881), Gavisson (1885); Italian works by Morselli (1880; Eng. trans. 1881), Carrieri (1883), Ferri (1884); O'Dea, *Suicide: Studies on its Philosophy, its Causes, and its Prevention* (New York, 1882); Westcott, *Suicide: its History, Literature, and Jurisprudence* (with bibliography, 1885); and some thirty other works cited in *Notes and Queries*, June 1890, p. 489. Also the articles INSANITY, EUTHANASIA, HARI-KARI, and SUTTEE. The suicide of Scorpions (q.v.) and snakes, often asserted, has been proved to be impossible.

Su'idæ, a family of even-toed, non-ruminant Ungulates, including pigs, hogs, or boars, the Babiroussa, and the wart-hogs (Phacochœrus). The snout is mobile but truncated; the feet have four toes, of which two reach the ground; the upper canine teeth curve more or less outwards or upwards; the molars bear rounded tubercles; the stomach is almost simple. In distribution they are entirely confined to the Old World.

Suidas, the reputed author of a *Lexicon*, though when he lived, or who he was, or whether he was even called Suidas, no one can say; but it is customary to place him about the 10th or 11th century. The *Lexicon* bears unmistakable evidence of having gone through many hands; and though we can fix the date when several of the articles *must* have been written, it is impossible to ascertain whether they are the composition of the first compiler or of a later editor. The work is a sort of cyclopædia, giving an explanation of words, and notices of persons, places, &c., in alphabetical order. It possesses almost no literary or critical merit, but is valuable for its numerous extracts from ancient writers, whose works in many cases have perished. The first edition appeared at Milan (1499); since then the best editions have been those of Küster (3 vols. 1705), Gaisford (3 vols. Oxf. 1834), Bernhardy (2 vols. Halle, 1834), and I. Bekker (1854).

Sui Juris, in the Roman law, the condition of a person not subject to the *Patria Potestas* (see FAMILY, Vol. IV. p. 542). The paterfamilias was the only member of a family who was *sui juris*, all the rest being *alieni juris*, including sons, unmarried daughters, the wife, and the wives and children of the sons of the paterfamilias. A son or unmarried daughter became *sui juris* on the death of the paterfamilias. In his father's lifetime a son could only become *sui juris* by emancipation.

Suir, a river of Ireland, flowing 85 miles southward and eastward, chiefly along the boundary of the counties of Tipperary, Waterford, Kilkenny, and Wexford, past Clonmel, Carrick, and Waterford, till it meets the Barrow, and immediately afterwards falls into Waterford Haven. It is navigable by barges as far as Clonmel.

Suite, a series of dances arranged for instruments in the same or relative keys, and usually preceded by a prelude.

Sukhum Kale, a fortified seaport town of the Caucasus, on the east coast of the Black Sea, 70 miles N. by W. of Poti. It stands on the site of the ancient Milesian colony of Dioscurias, and since 1809 has been alternately in the hands of the Turks and the Russians; the latter have held it since 1877. Pop. 1947.

Sukkur, a town on the right bank of the Indus, 28 miles by rail SE. of Shikarpur; it is connected by rail also with Karachi (Kurrachee), and is the terminus of the Bolan Pass Railway to Afghanistan. The river is crossed by a magnificent cantilever bridge (1889), or rather by two bridges (one with a span of 820 feet), resting upon the fortified island of Bukkur in the middle of the channel. New Sukkur, which grew up after the British occupied (1839) the fort on Bukkur, has considerable trade in silk, cloth, cotton, wool, opium, saltpetre, sugar, brass utensils, piece-goods, metals, wines and spirits. Pop. (1834)

4000; (1872) 13,318; (1881) 27,389. Old Sukkur, about a mile away, has a good many old tombs in its immediate vicinity.

Suleiman Pasha, Turkish general, was born in Roumelia in 1838, entered the Turkish army in 1854, fought in Montenegro, Crete, and Yemen between that date and 1875, and in the intervals of peace taught in the Military Academy at Constantinople, and finally presided over it as director. He greatly distinguished himself as a corps commander against the Servians in 1876, and was in 1877 nominated governor of Bosnia and Herzegovina. When the Russians declared war (1877) against Turkey Suleiman checked them at Eski Zagra, and destroyed his army in heroic but vain attempts to force them from the Shipka Pass. In October he was appointed commander-in-chief of the army of the Danube, but failed to accomplish anything, retreated behind the Balkans, and suffered defeat near Philippopolis (January 1878). Brought before a court-martial, he was condemned to be degraded and kept in a fortress-prison for fifteen years. The sultan, however, pardoned him, and he died on 15th April 1883. See Lord Houghton's *Monographs* (1873).

Suliman or SULAIMAN HILLS, a mountain-range upwards of 350 miles in length, running in a straight line from north to south, and forming the historic boundary between Afghanistan and the Punjab, India. The highest summit of the range, Takht-i-Sulaiman (Solomon's Throne), 11,295 feet high, was first ascended by a European, Major Holdich, in 1883. The general appearance of the range is rocky, precipitous, and bare of trees.

Sulina, one of the lower branches of the Danube (q.v.). The town of Sulina, on its south bank and near its mouth, has a lighthouse and 5000 inhabitants. Bombarded by the Russians in 1877, it has been a free port since 1879.

Suliotes, a tribe who inhabited the valley of the ancient Acheron, in the Pashalik of Janina (*Epirus*) in European Turkey, are a mixed race, being partly of Hellenic and partly of Albanian origin. They are the descendants of a number of families who fled from their Turkish oppressors to the mountains of Suli (whence they derive their name) near Parga during the 17th century. In this corner of the Turkish empire they prospered, and towards the close of the 18th century numbered 560 families, inhabiting 90 hamlets. For several years they heroically resisted the attempts of the Turks to deprive them of their independence. But vanquished at length (1803), they retreated to the Ionian Islands, where they remained till 1820, when Ali Pasha, finding himself hard pressed by the Turks, invoked their aid. The Suliotes, eager to return to their home, threw in their lot with him, but were ultimately forced to surrender their stronghold of Suli to the Turks, and again to flee from their country. About 3000 of them took refuge in Cephalonia, though large numbers preferred to skulk in the neighbouring mountains. Though they took a glorious part in the war of Greek independence, their country was not included by the treaty of 1829, nor by the extension of 1881, within the Greek boundary line. Nevertheless most of them established themselves in Greece, where their leaders were raised to important offices. See Perrhaebos' *History of Suli and Parga* (1815; Eng. trans. 1823).

Sulla, LUCIUS CORNELIUS, surnamed by himself FELIX, a scion of the illustrious house of the Cornelii, was born in 138 B.C. His limited patrimony was sufficient to secure him a good education, and his youth was spent not more in the pursuit of pleasure than in the study of the Greek and Roman authors. The liberality of his stepmother increased his slender means, and enabled him to aspire to the honours of the state. As quæstor in 107 under Marius in Africa he crowned a series of important successes by inducing Bocchus, the Mauritanian king, to surrender Jugurtha, whom he brought in chains to the Roman camp (106). The war of the Cimbri and Teutones (104–101) saw Sulla again serving under Marius, whose jealousy, however, drove him to take a command under the other consul, Quintus Catulus. In 93 he was prætor, and in 92 proprætor in Cilicia, where the senate sent him with special orders to restore Ariobarzanes to the throne of Cappadocia, from which he had been expelled by Mithridates. After achieving a complete success, Sulla returned to Italy in 91. The private hatred of Marius and Sulla began now to take on a political aspect, as the aristocratic tendencies of the latter grew prominent. Their long-smouldering animosity was on the point of bursting forth, when the breaking out of the Social War hushed all private quarrels for the time. The aged Marius had now the deep mortification of finding his military achievements thrown into the shade by the brilliant successes of his rival. The expectations of Marius were dashed to the ground when the senate bestowed on Sulla, after his consulship in 88, supreme command in the Mithridatic war. Marius rushed headlong into treason and civil strife. Then followed the expulsion of Sulla from Rome, his triumphant return at the head of his devoted legions, the overthrow of the Marian party, and the first proscription. By the beginning of 87 Sulla was able to embark for the East. During the four years he spent there he won the victories of Chæronea (86) and Orchomenus (84) against Archelaus, the general of Mithridates. Next he crossed the Hellespont, crushed Fimbria, who had obtained the command of the army sent out by the Marian party (which, in Sulla's absence, had again got the upper hand in Italy), forced Mithridates to sue for peace, then sailed for Italy and landed at Brundusium (83). The victory over the Samnites and Lucanians at the Colline gate brought the struggle to a close (82), and Sulla was now master of Rome and Italy. Then followed his dictatorship, and the period of the proscriptions (81)—a virtual reign of terror, in which of senators were slain perhaps from one to two hundred, of knights between two and three thousand. During the next two years several very important constitutional reforms were carried, mostly reactionary, and tending to increase the authority of the senate. The restoration of the *judicia* to the senate, the abolition of the functions of the *comitia tributa*, the withdrawal from the tribunes of the right to summon the *comitia*, the doubling of the number of the senate, the annual election of twenty quæstors, the enactments that no man should be prætor without having been quæstor, or consul without having been prætor, and that *tribuni plebis* should be eligible for no other office, the institution of *quæstiones* without appeal confined to special classes of crimes—these were some of the provisions of a legislation, with a few exceptions, doomed to fall within ten years. In 79 Sulla resigned the dictatorship and retired to his estate at Puteoli, where, surrounded by buffoons and dancers, he indulged to the last in every sensual excess of which his exhausted frame was capable. He died in 78, at the age of sixty. His monument in the Campus Martius bore an inscription, attributed to Sulla himself, which said that none of his friends ever did him a kindness, and none of his foes a wrong, without being largely requited.

Sulla's manners were haughty and morose, though not devoid of a certain sensibility, for he was easily moved, it is said, even to tears, by a tale of sorrow. His keen observation enabled him to see in young Cæsar, in spite of a careless temper and dissipated habits, what would yet prove 'more than one Marius.' His eyes, we are told, were of a piercing blue, and his complexion was disfigured by pimples and blotches, compared by the raillery of the Greeks to a mulberry sprinkled with meal.

Sullivan, Sir Arthur Seymour, was born in London, 13th May 1842. He studied music under Sterndale Bennett and Goss, and at Leipzig, and had his music to *The Tempest* performed at the Crystal Palace in 1862. He then produced the cantata *Kenilworth* in 1864, the overtures *In Memoriam* (1866), *Marmion* (1867), and *Di Ballo* (1869), the oratorios *The Prodigal Son* (1868) and *The Light of the World* (1873), a Festival Te Deum for the Prince of Wales's recovery in 1872, and at Leeds in 1880 and 1886 *The Martyr of Antioch* and *The Golden Legend*. To the general public, however, he is better known by his hymn tunes, his songs, and still more his tuneful and popular operas and operettas. The latter began with *Cox and Box* in 1866, and include the long list given already in the article on W. S. Gilbert (q.v.); they are notable for an orchestration full of subtle and humorous touches that render his operas of special interest to musicians. The fertility and technical resource squandered on these productions were devoted to higher work in the grand opera of *Ivanhoe* (1891). He was the first principal (1876–81) of the National Training School for Music, was made Mus. Doc. of Cambridge in 1876 and of Oxford in 1879, received the Legion of Honour in 1878, and holds other foreign decorations; and in 1883 he was knighted.

Sullivan, Barry, tragedian, born at Birmingham in 1824, first appeared at Cork in 1840, played at Edinburgh and elsewhere, and at the Haymarket in London as Hamlet in February 1852. He visited America in 1857–60, and Australia in 1861–66. He was afterwards for a while lessee of the Holborn Theatre; but he was more popular in the provinces, especially in Ireland and the west of England. He died at Brighton, 3d May 1891.

Sully, Maximilien de Bethune, Duke of, the famous minister of Henry IV. of France, was the second of the four sons of François, Baron de Rosny, and was born at the château of Rosny near Mantes, 13th December 1560. At an early age he was committed to the care of Henry of Navarre, head of the Huguenot party, narrowly escaped the St Bartholomew massacre (1572), and accompanied Henry in his flight from court (1576). He took an active part in the war, had command of the artillery at Coutras (1587), and helped materially to decide the victory. He reached Ivry but an hour and a half before the battle, but was fortunate enough, though severely wounded, to capture the white standard with black crosses of Mayenne. He approved of the king's politic conversion, and throughout the whole of the reign remained his most trusted counsellor. His first task was to repair the ruinous finances of the realm, and to this gigantic labour he gave himself with an energy and persistence that entitle him to rank with Richelieu and Colbert among the few great ministers of France. Before his time not half the nominal sum raised from taxes reached the treasury, the whole administration being an organised system of pillage; but Rosny made a tour through the provinces armed with absolute authority, personally examined the accounts, discovered the actual delinquents, and dismissed or suspended them, besides compelling them to disgorge their ill-gotten gains into the treasury. All this he effected with iron rigidity and persistence, heedless of the clamour and hatred of all the army of dishonest tax-gatherers and revenue-farmers, however high in station. In 1596, according to Henri Martin, the disposable revenue of the state was but nine millions of livres; in 1609 it was no less than about twenty millions, with a surplus as great in the treasury, and the arsenals and fleet besides in an excellent state of equipment. He brought actual order out of chaos, and would have done yet more for France but for the vast expenditure of the pleasure-loving king and his mistresses. Yet Sully was no far-seeing or philosophical financier, but only a dexterous master of expedients. He made no great innovations, but, if not a genius of creation, he was undoubtedly one of order. He distrusted manufactures as a source of prosperity, his main economic ideas summed up in his well-known aphorism, 'Labourage et pâturage sont les deux mamelles qui nourissent la France.' His own honesty has been impugned by hasty writers, but, even if he himself grew rich in his years of office, there is absolutely no proof that he ever robbed his master.

In February 1601 he became grand-master of the artillery, and in March 1606 he was created Duke of Sully. After the assassination of his master he was forced to resign the superintendence of finance, but was allowed to retain the care of the woods and the artillery, and was even presented by Marie de Médicis with a reward of 300,000 livres. But his reign was at an end, and ere long he retired to his estate, surviving till December 22, 1641. In his retirement his Memoirs were compiled by his secretaries, and submitted to him, being actually composed in the awkward and tedious fashion of a narrative addressed to himself. Here naturally his own actions are put in the most favourable light; yet, although the judicious student will by no means accept the whole as completely historical, the work remains a document of priceless value for the reign of Henry IV. Chapter vi., treating of the remorse of Charles IX. after St Bartholomew, was copied from an earlier MS., doubtless entirely Sully's own work, and is an admirable example of direct and vigorous writing. The first and second folio volumes were printed under Sully's own eye (undated, but really in 1634); the third and fourth volumes were printed at Paris in 1662. These last contain the famous scheme of the countries of Europe, with the exception of Russia and Turkey, grouped into a grand Christian republic of fifteen states, kept in equilibrium by the magnificent chimera of an international Amphictyonic Assembly, with a rational rearrangement of boundaries and toleration for different faiths. The scheme is no doubt a dream of Sully's rather than Henry's brain, although it may well be that its germ may have been found in the careless talk of the king with his trusted minister as they paced together the broad walk of the Arsenal gardens.

Sully was a harsh and unamiable man, of vast self-esteem and little humour; but his unpopularity was a natural enough fruit of his inflexibility of principle, and his devotion to the interests of France and the person of his king it is absolutely impossible to gainsay.

The full title of his work is its best description: 'Mémoires des sages et royales Économies d'État, domestiques, politiques et militaires de Henri le Grand, l'exemplaire des rois, le prince des vertus, des armes, et des lois, et le père en effet de ses peuples françois; Et des Servitudes utiles, obéissances convenables et administrations loyales de Maximilian de Béthune, l'un des plus confidents familiers et utiles soldats et serviteurs du grand Mars des François; Dédiés à la France, à tous les bons soldats et tous peuples françois.'

Marbault, secretary of Sully's chief rival, Du Plessis-Mornay, wrote a severe criticism on the *Mémoires*—the foundation of the unhistorical and calumnious article on Sully in the *Historiettes* of Tallemant des Réaux. The singular form in which the *Mémoires* was cast proved so intolerable to the 18th century that the Abbé de l'Écluse in 1745 re-edited the whole in ordinary form of narrative, but modernised and spoiled the work. The original text may be found in the collection of Michaud and Poujoulat (vols. xvi.-xvii.). See Sainte-Beuve's *Causeries du Lundi*, vol. viii.; also the books by Legouvé (1873), Gourdault (3d ed. 1877), Bouvet de Cressé (1878), Dussieux (1887), and Chailley (1888); also Ritter's study of the Memoirs (Munich, 1871).

Sully-Prudhomme, RENÉ FRANÇOIS ARMAND, a great French poet, was born at Paris, 16th March 1839, and after the early death of his father was brought up by his uncle, a notary, for his own profession. He studied the sciences, law, and philosophy, but soon devoted himself entirely to letters, and in 1865 published his first volume of poems, *Stances et Poèmes*, which had the good fortune to gain and to deserve the praises of the veteran critic Sainte-Beuve. One poem, the 'Vase brisé,' at once became widely popular. Later volumes, *Les Épreuves, Croquis Italiens, Les Solitudes, Impressions de la Guerre, Les Destins, Les Vaines Tendresses, La France, La Révolte des Fleurs*, extended his fame as a poet of great delicacy of feeling, as well as subtlety and depth of thought. His finest poems are steeped in a serene but penetrating melancholy, and almost all reveal sincerity of inspiration, nobility of aims, and an austere beauty of form that sometimes attains perfection. But he has ever been a thinker wrapped up in a poet's robe, and the things nearest his heart have been the graver questions of life and death, of good and evil. Masterpieces of analytic subtlety are his great didactic poems *La Justice* (1878) and *Le Bonheur* (1888), but the question remains debatable whether these themes really admit of poetic treatment. Other works are an accurate but somewhat harsh metrical translation of the first book of Lucretius (new ed. 1886); *L'Expression dans les Beaux Arts*, a contribution to the history of art; and *Réflexions sur l'Art des Vers* (1892). His *Œuvres Complètes* appeared in five volumes, 1882–88. He was elected to the Academy in 1881. See Caro, *Poètes et Romanciers*; and Jules Lemaitre, *Les Contemporains* (series i. and iv.).

Sulmona, or SOLMONA, a city of Italy, 80 miles by rail E. of Rome. It stands 1575 feet above sea-level, has a cathedral (1119), and paper and fulling mills. Here were born Ovid and Pope Innocent VII. On a mountain close by stood until 1870 the 'mother monastery' of the Celestines (q.v.). Pop. 14,171.

Sulphates. See SULPHURIC ACID; and for sulphides and sulphites, see SULPHUR.

Sulphocyanates, or SULPHOCYANIDES, are prepared by fusing cyanides with sulphur. These salts do not possess the poisonous character of the cyanides. *Sulphocyanide of potassium*, KCNS, is anhydrous, but very deliquescent, and occurs in long streaked colourless prisms, somewhat resembling nitre both in appearance and taste; it is extremely soluble in water, and fuses on the application of a gentle heat. The *sulphocyanide of mercury* is a white powder which possesses the property of swelling or growing in size to an almost incredible degree when moderately heated. The resulting mass often assumes a most fantastic shape, and is sufficiently coherent to retain its form; it is of a yellow colour externally, but black within. It is this sulphocyanide which is the ingredient of the toy known as 'Pharaoh's serpents.' Each serpent consists of a little cone of tinfoil, resembling a pastille in shape, and filled with the above-named compound. On lighting the cone at the apex, there begins to issue from it a thick serpent-like coil, which continues twisting and increasing in length to an extraordinary degree, the serpent-like shape resulting from the salt being burned in the tinfoil cone.

Sulphonal, a synthetical hypnotic now largely used, of highly complex composition, with the formula $(CH_3)_2C(SO_2C_2H_5)_2$. It forms colourless tasteless crystals, very slightly soluble in cold water. For sleeplessness it is given in doses of 15 to 45 grains, but opinions differ as to the place it will ultimately take in medicine.

Sulphonic Acid. See DYEING, p. 142.

Sulphur is one of the most important of the non-metallic elements; sym. S, eq. 32, sp. gr. of rolled sulphur 1·98, and of amorphous sulphur 1·957; sp. gr. of vapour 6·617 at 900° (482° C.) and 2·2 at 1904° (1040° C.), atmospheric air being the unit of comparison for the vapour. At ordinary temperatures it exists as a solid, brittle, tasteless, and inodorous body, of a characteristic yellow colour, and insoluble in water. A piece of solid sulphur, heated to a temperature of 239° (115° C.), fuses into a thin yellow liquid; while in closed vessels it may by further heat be distilled, the boiling-point being about 836° (446° C.), and at this temperature it yields a deep yellow vapour of sp. gr. 6·617. When the sulphur-vapour comes in contact with cold air it condenses in the form of a fine yellow powder, known as *Flowers of Sulphur*. If fused sulphur be rapidly cooled it solidifies into a compact mass, of a granular crystalline texture; and if, in its liquid state, it be allowed to run into cylindrical wooden moulds, we obtain the ordinary roll-sulphur, or common brimstone. If allowed to cool slowly, it crystallises in long, glistening, deep yellow, oblique prisms, with a rhombic base, which, however, soon lose their most characteristic properties. As native sulphur is frequently met with in yellow crystals, whose form is derived from the octahedron with a rhombic base, it is obviously a dimorphous substance. Sulphur exists in several allotropic forms, red, black, or brown. When sulphur is heated it melts and forms a mobile amber-coloured liquid, which, by continued heat, gradually darkens, at the same time becoming more viscid, until a temperature of 356° (180° C.) is reached. Even though the heat be still continued, the temperature remains stationary for a time, but eventually it rises gradually to 500° (260° C.), the melted sulphur becoming less viscid. If at this stage it is poured into cold water it forms a tenacious ductile mass, which can be drawn out into threads having a certain amount of elasticity. In the course of a few hours these become brittle, and are seen to be crystalline in structure and in no way different from the original sulphur.

Sulphur is a bad conductor of heat, and the mere heat of a warm hand often causes it to crackle or even to fall to pieces, from the unequal expansion. It is an insulator of electricity, and becomes negatively electric by friction. It is slightly soluble in alcohol, ether, and the fatty oils; its best solvents being the bisulphide of carbon and chloride of sulphur. When it is heated in the air it takes fire at about 470° (243° C.), burning with a blue flame, and becoming converted into sulphurous acid, whose pungent suffocating fumes are characteristic of sulphur. This element is second only to oxygen in its powerful affinity for other elements, with most of which it unites, and often in several proportions. With most of the metals it combines very readily, and in some cases with a development of light and heat; thus, silver and copper burn in sulphur-vapour just as iron-wire or zinc-foil burns in oxygen. In consequence of its power, with the aid of heat, of forming sulphurous acid with the oxygen of the air, and thus rendering the latter incapable of supporting combustion, burning sulphur may be usefully employed for the extinguishing of fire—as, for example, in chimneys.

Sulphur occurs very widely distributed in the mineral kingdom, partly free and partly combined with other elements. The free sulphur is either found pure in regularly formed crystals, or intimately mixed with earthy matters. Sulphur is usually plentiful in volcanic districts; most of what is used in Europe has been obtained from Sicily (which in 1880-90 exported from 213,000 to 350,000 tons yearly), but of late large quantities are recovered from the waste of soda manufacture, and sulphur has been actually exported from Newcastle to Italy (see SODA, p. 553). Sulphur is found in many parts of the United States, and some Californian deposits have been utilised to a small extent, but have been unable to compete with Sicilian sulphur. In the form of sulphide, sulphur occurs abundantly in combination with iron, copper (iron and copper pyrites), lead (galena), zinc (blende), &c., the bisulphide of iron (or iron pyrites) furnishing most of the sulphur that is employed in the manufacture of sulphuric acid. Many of the metallic sulphides (formerly known as *Sulphurets*) occur native, and form highly valuable ores. They are all solid at ordinary temperatures, and, with the exception of those of potassium, sodium, calcium, strontium, barium, and magnesium, are insoluble in water; they are, moreover, conductors of electricity. Many of them, especially of those that occur native, exhibit very brilliant and characteristic colours. The same metal may have several sulphides, and in general there is a sulphide for each oxide. The sulphides are, however, sometimes the more numerous. Sulphur is still more extensively distributed in the form of sulphates, as in the sulphates of lime, magnesia, baryta, &c. In the vegetable kingdom sulphur is a constituent of Albumen (q.v.), and of the volatile irritant oils of mustard, garlic, asafœtida, &c.; moreover vegetable juices contain it in the form of certain sulphates. In the animal kingdom it is not only a constituent of the albuminous, fibrinous, and gelatinous tissues, but of the hair, saliva, bile, urine, &c.

The grosser impurities of sulphur are removed by crude processes of fusion and distillation at or near the place from whence it is obtained. What is called refined sulphur is purified by distillation in a large cast-iron still, and condensed in a receiver kept cool. When the vaporised sulphur is condensed in a large chamber it is obtained in the form of sublimed sulphur, or flowers of sulphur; but as the walls get hot it melts and collects on the floor, and is run into cylindrical wooden moulds, from which, when cool, it is taken out as roll or stick sulphur. The residue left in the retort is a mixture of sulphur with various impurities. Under the name of black sulphur, or *Sulphur vivum*, it is used in veterinary medicine, and for the purpose of dressing mouldy hops. Sulphur is thrown down from certain of its compounds (as from a strong solution of a polysulphide of calcium, sodium, or potassium) by dilute hydrochloric acid; it falls as a grayish-white, very fine, light powder, known in the Materia Medica as milk of sulphur, or precipitated sulphur. The most common impurities met with in ordinary commercial sulphur are selenium and realgar (bisulphide of arsenic). Flowers of sulphur frequently exhibit a slight acid reaction, in consequence of a little sulphurous acid clinging to them. By rinsing them with water this impurity is at once removed.

Sulphur is extensively employed in the arts and manufactures, as in the manufacture of some matches, gunpowder, &c. When converted into sulphurous acid it is employed as a powerful bleaching agent, as also for the destruction of insects, fungi, &c.; but its chief consumption is in the manufacture of sulphuric acid.

The eight compounds of sulphur and oxygen, when combined with water, present the characters of acids. These acids have this composition:

Hyposulphurous	acid	H_2SO_2
Sulphurous	"	H_2SO_3
Sulphuric	"	H_2SO_4
Thiosulphuric	"	$H_2S_2O_3$
Dithionic	"	$H_2S_2O_6$
Trithionic	"	$H_2S_3O_6$
Tetrathionic	"	$H_2S_4O_6$
Pentathionic	"	$H_2S_5O_6$

We shall here notice the most important members of this group—the second, third, and fourth; the third, *Sulphuric Acid*, is discussed in a special article. (The last four derive the essential part of their name from the Greek *theion*, 'sulphur.')

Sulphurous Anhydride (often called Sulphurous Acid), SO_2, occurs under the ordinary relations of temperature and pressure as a colourless gas, possessing the suffocating odour of burning sulphur. In its concentrated form it is quite irrespirable, and in a diluted state it excites cough. It not only is incapable of burning, but it rapidly extinguishes the flame of burning bodies. It is very freely soluble in cold water, which at 32° (0° C.) takes up nearly 69 times its volume of the gas, while at 75° (24° C.) it only takes up 32 volumes; the solution known as *Aqueous Sulphurous Acid* having at first the same smell and taste as the gas, but soon absorbing oxygen from the air, and becoming converted into sulphuric acid. By the action of cold sulphurous acid may be condensed to a colourless transparent limpid liquid, which freezes at -105° (-76° C.), forming a transparent crystalline solid. The specific gravity of the gas is 2·247 (atmospheric air being the unit), and that of the liquid is 1·49 (water being the unit), the solid being considerably heavier. Although dry sulphurous acid gas and dry oxygen when mixed exert no action on one another, there are many conditions under which sulphurous acid rapidly absorbs oxygen, and is converted into sulphuric acid—e.g. if the gas be dissolved in water; a similar action takes place under the influence of hydrated nitric acid, iodic acid, and certain metallic oxides. Hence sulphurous acid is a powerful reducing or deoxidising agent. This gas is a common and abundant product of volcanic action, and is occasionally met with in solution in the springs in volcanic regions. It may be prepared artificially by simply burning sulphur in the air or in oxygen gas, or by heating in a flask 4 parts of flowers of sulphur mixed with 5 parts of powdered black manganese, sulphurous acid and sulphide of manganese being the products, as shown by the equation $S_2 + MnO_2 = SO_2 + MnS$. In consequence of its solubility in water this gas should be collected over mercury. In addition to the uses of sulphurous acid as a bleaching agent, it is valuable both as a disinfectant agent and as a powerful antiseptic, and has been used as an application for lumbago, &c. But by far its most important use is in the manufacture of sulphuric acid. In combination with bases this acid forms the *sulphites*—a class of salts which, excepting the sulphite of soda, are of little importance, except for their power when moist of extracting oxygen, and thus acting as reducing agents. The salts of the sesquioxide of iron are reduced by them to salts of the protoxide.

Thiosulphuric Acid, $H_2S_2O_3$, formerly called Hyposulphurous Acid, is, as yet, only known in a state of combination with bases; for on attempting to separate the acid from the base the former becomes decomposed into sulphur and sulphurous acid. The most important of its salts is the *Hyposulphite of Soda*, $Na_2S_2O_3 + 5H_2O$, described in the article SODIUM. This and other soluble hyposulphites may be easily recognised by the facility with which they dissolve the haloid salts of silver, forming a solution of an extremely sweet taste, and containing a double hyposulphite of silver and soda, with an admixture of chloride, iodide, or bromide of sodium. It is this power of dissolving those salts of silver which are insoluble in water that renders the hyposulphite of soda useful in photography.

With hydrogen sulphur forms two compounds: (1) *Persulphide of Hydrogen*, an oily liquid, having the smell and taste of sulphuretted hydrogen; (2) *Sulphuretted Hydrogen*, H_2S, known also as Hydrosulphuric Acid and Sulphydric Acid, a natural gaseous constituent of many Mineral Waters (q.v.), as for instance Harrogate and Strathpeffer in Great Britain. It is formed spontaneously wherever organic compounds containing sulphur undergo putrefaction, as in stagnant sewers and cesspools and in waters charged with organic matter and sulphates. By acting on sulphide of iron with dilute sulphuric acid, sulphate of iron is produced and sulphuretted hydrogen liberated.

$$FeS + H_2SO_4 = FeSO_4 + H_2S.$$

Sulphuretted hydrogen is a poisonous colourless gas, with the nauseous odour of rotten eggs. By pressure it may be liquefied and solidified. It is soluble in one-third of its volume of water; but the solution does not keep well unless preserved from contact with air. It is readily combustible, burning with a blue flame, and forming water, sulphurous acid, and usually a little sulphur. It has a weak acid reaction, but combines readily with bases forming sulphides. It is very poisonous, birds perishing in air containing $\frac{1}{1500}$ part, and dogs in air containing $\frac{1}{300}$ part of the gas. Owing to its presence in illuminating gas silver becomes tarnished in rooms where gas is burned, while librarians find the bindings of their books become corroded by the sulphuric acid eventually produced by the combustion of the gas. From its property of forming insoluble sulphides with most metals, sulphuretted hydrogen is the sheet anchor of the analytical chemist. These insoluble sulphides again are some of them produced in an acid solution, and some only in an alkaline one. It follows that by first acidifying the solution to be analysed and then adding the sulphuretted hydrogen certain metals will be removed as insoluble precipitates, while others will have been unaffected. On now adding an alkali a second portion will be removed, and so a working method of separating the metals can be devised. The simplest test for sulphuretted hydrogen at the mouth of a drain is the use of blotting-paper soaked in solution of acetate of lead. This rapidly turns brown in presence of the gas.

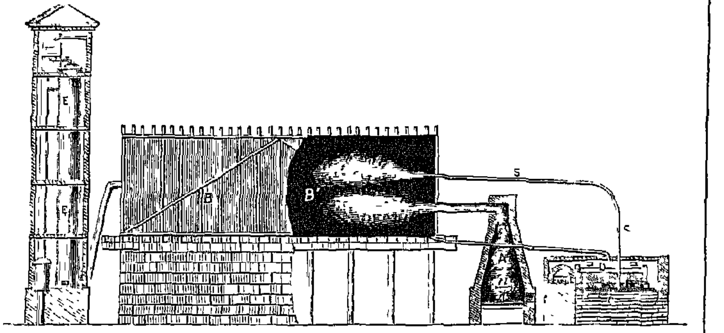
Sulphur combines with carbon to form *Bisulphide of Carbon*, CS_2, a colourless, inflammable liquid, heavier than water, and having a disagreeable odour and taste. It is soluble in alcohol, but not in water, and it is a powerful solvent of fats, sulphur, phosphorus, and india-rubber. Owing to its high refractive power it is used in the construction of prisms. It may be obtained by heating fragments of charcoal to bright redness in a porcelain tube, and passing sulphur vapour along it. Its vapour when freely inhaled exerts an anæsthetic action similar to that of chloroform and ether. Workmen in caoutchouc or other manufactures in which bisulphide of carbon is used as a solvent suffer from prolonged exposure to its vapour, which produces headache, loss of appetite, impairment of vision and hearing, and causes general derangement of health by its deleterious action on the nervous system.

Sulphur combines with chlorine in several proportions, the most important of these compounds being the *Dichloride of Sulphur*, SCl_2, and the *Chloride of Sulphur*, S_2Cl_2. Both of them are liquids, and are formed by the direct action of the combining elements. The chloride is a yellow liquid which is decomposed by contact with water—sulphur, hydrochloric, and other acids being produced. It is capable of dissolving about 67 per cent. of sulphur at an ordinary temperature, and, like bisulphide of carbon, is extensively employed in vulcanising india-rubber. The dichloride of sulphur is formed by saturating the chloride with chlorine; a deep-red liquid, resembling the previous compound in most of its properties; it is decomposed by the sun's rays into the chloride and free chlorine.

Sulphur seems to have been known from the earliest times, and sulphuric acid was most probably known to the Arabians; the English manufacture of sulphuric acid dates, however, only from the 18th century. Sulphur is used for various purposes in medicine. It is given internally either as sublimed sulphur (flowers of sulphur) or as precipitated sulphur (milk of sulphur), in somewhat large doses, as a mild cathartic—generally combined with jalap and cream of tartar. The *Confection of Sulphur* of the Pharmacopœia is composed of sulphur, cream of tartar, and syrup of orange-peel rubbed together—the dose being from half an ounce to an ounce, or from one to two tablespoonfuls. In small doses sulphur is of great value in cases of atonic gout and chronic rheumatism. The external use of sulphur in the form of ointment has been already noticed in the article ITCH. It is also used externally in other cutaneous disorders, particularly in lepra and psoriasis; its application in the form of vapour is often of service.

Sulphuric Acid, H_2SO_4, is the chemical name of the liquid commercially known as *Oil of Vitriol*—so called from its having been first produced by the distillation of green vitriol (sulphate of iron). It is an odourless, dense, oily-looking liquid, sp. gr. 1·842. When pure it is colourless, but usually it is of a straw to brown colour, derived from impurities which have fallen into it and been charred. It has all the properties of a typical acid, being intensely corrosive and changing vegetable colours. Exposed to the air it absorbs water, and when mixed directly with water great heat is evolved, the liquids contracting in bulk. It does not evaporate at ordinary temperatures, and dilute solutions spilt on cloth gradually become stronger till the acid begins to destroy the fibres of the cloth. Oil of vitriol, or the protohydrate, is not the only hydrate of sulphuric acid. Three others are known to exist. When the fuming oil of vitriol of Nordhausen is exposed to a low temperature a white crystalline substance separates, which is a hydrate, containing half as much water as the common liquid acid; its formula is $H_2SO_4SO_3$, and its fusing-point is 95° (35° C.). Again, a mixture of 49 parts of the strong liquid acid and 9 parts of water freezes at 47° (8·3° C.), and crystallises into splendid rhombic prisms, from which property it is often termed *glacial sulphuric acid*, with sp. gr. 1·780. Lastly, when a very dilute acid is concentrated by evaporation *in vacuo*, at 212° (100° C.), till it ceases to lose weight, there will be a resulting compound, consisting of 40 parts of the real acid and 27 of water, and represented by the formula $H_2SO_42H_2O$. The compound formerly known as *anhydrous sulphuric acid* possesses none of the characteristic properties of an acid; see SULPHURIC ANHYDRIDE.

Sulphuric acid in its free state is a very rare natural product; although in combination with bases it is common in the animal and vegetable, and abundant in the inorganic kingdom. In plants it exists in the juices, and in animals in the blood and its derivates chiefly in the form of sulphates of the alkalies; while in the mineral kingdom it occurs as gypsum (sulphate of lime), heavy spar (sulphate of baryta), celestine (sulphate of strontia), &c. It may be prepared on a small scale by boiling sulphur in *aqua regia* or in nitric acid, the sulphur becoming gradually oxidised into sulphuric acid. As a general rule, however, the commercial acid is employed even for laboratory experiments. In order to obtain the acid in a pure form, suitable for medical use or medico-legal analysis, it must be redistilled with sulphate of ammonia in a retort containing a few slips of platinum foil, the first and last portions being rejected. The distillation is attended with violent concussions, partly owing to the high specific gravity of the acid, and partly owing to its high boiling-point, and this convulsive action is moderated mechanically by the platinum slips. Sulphuric acid thus prepared according to the directions of the British Pharmacopœia may be regarded as perfectly pure, presuming arsenic is not present. Strong sulphuric acid has comparatively little action on the metals except at a high temperature, when it dissolves them, and at the same time undergoes partial decomposition; the metal being oxidised by a portion of the acid which becomes decomposed into oxygen and sulphurous acid, and then uniting with a portion of undecomposed acid to form a sulphate. Silver, copper, mercury, arsenic, antimony, bismuth, tin, lead, and tellurium are thus acted on. Gold, platinum, rhodium, and iridium are not affected by the acid even at a boiling temperature. The more oxidisable metals, such as zinc, iron, nickel, and manganese, are readily soluble in the dilute acid, water being decomposed and hydrogen liberated, while the oxygen of the water unites with the metal; and the metallic oxide, at the moment of its formation, combines with the sulphuric acid to form a sulphate.



A, sulphur-burner, or furnace; B, lead chamber, shown in section at B'; C, steam-boiler; D, leaden pan; E, coke tower; S, steam-pipe; *n*, nitre pot.

The *sulphates*—or salts formed by the combination of sulphuric acid with a base—are generally composed, as in the case of green vitriol, $FeSO_4,7H_2O$, of 1 equivalent of acid and 1 of metallic oxide, with or without water of crystallisation. With the alkalies this acid also forms acid salts, as bisulphate of potash, and in a few cases—copper, for example—it forms basic salts. The insoluble sulphates, such as that of baryta, may be obtained by precipitating a soluble salt of the base by a soluble sulphate; thus, nitrate of baryta and sulphate of soda yield an insoluble sulphate of baryta and nitrate of soda, which remains in solution. The soluble sulphates may be prepared by dissolving the oxide or carbonate in dilute sulphuric acid, in those cases in which the metal itself is not readily attacked by the acid. Sulphuric acid and the soluble sulphates are easily detected by their yielding, with a solution of a baryta salt, a white precipitate of sulphate of baryta insoluble in acids.

Sulphuric acid is prepared on a large scale by two distinct processes—viz. by the distillation of green sulphate of iron—the original process of Basil Valentine (15th century); and by the oxidation of sulphurous acid through the agency of nitrous acid and hyponitric acid. The first process is chiefly employed at Nordhausen in Germany. The sulphate of iron is distilled in earthen retorts, and the acid passes over into a receiver containing a little ordinary sulphuric acid, forming a brown fuming oily liquid, of about sp. gr. 1·900. This acid is known in commerce as Nordhausen acid, and is chiefly used for dissolving indigo.

The second method is that universally followed in Great Britain, the germs of which were likewise discovered by Valentine. He observed that when the fumes of burning sulphur were collected under a bell jar, slightly moistened with water, a small quantity of liquid was deposited. This liquid, which was simply sulphuric acid, on being concentrated from its solution by boiling was long sold as oil of sulphur at prices as high as 2s. 6d. per ounce. About the year 1740 the French chemists Lefevre and Lemery suggested that, by the use of nitre along with the sulphur, the operation might be conducted in close vessels, and a much greater quantity of acid might be produced. This idea was acted on in England by Dr Ward, who established works at Twickenham and Richmond, conducting his manufacture by burning the mixed sulphur and nitre in large stoppered glass receivers, into each of which a small quantity of water was first introduced. The substitution, in 1746, by Dr Roebuck of Birmingham, of lead chambers in place of the glass vessels may be regarded as essentially the establishment of the process of manufacture followed at the present day.

The first stage in the manufacture of sulphuric acid is the preparation of sulphurous acid by the burning of sulphur or of iron pyrites. Previous to the year 1838 Sicilian sulphur was almost exclusively used in the manufacture, but in that year the establishment of a monopoly of the sulphur trade by the Sicilian government, and its consequent increase in price, diverted the minds of manufacturers to the employment of iron pyrites (sulphide of iron). Iron pyrites is now much more used than sulphur, and the only hindrance to its universal adoption is the presence of foreign matter in the pyrites, the most deleterious being arsenical compounds; and it has hitherto been found impracticable to free the sulphuric acid wholly from the arsenious acid which renders it inapplicable for many purposes.

When sulphur is the material used for producing the sulphurous acid it is burned in an oven or 'burner' (A) of brickwork, having a sole or bottom of iron, termed the 'burner-plate.' Under this a small fire is at first lighted, which is allowed to go out after the sulphur has ignited. A little above the sulphur a small pot, called the nitre pot, *n*, is either placed on a stand or hung from the roof, filled with a quantity of either nitrate of soda or nitrate of potash, with sulphuric acid sufficient for its decomposition—8 or 10 lb. of the nitre with 5 or 6 lb. of sulphuric acid being allowed for every cwt. of sulphur. The decomposition of the nitre by the action of heated sulphuric acid furnishes nitric acid fumes, which go over into the chamber along with the sulphurous acid. The sulphurous acid readily abstracts from the nitric acid the additional oxygen required for its conversion into sulphuric acid, reducing the nitric acid to nitric oxide, NO. Nitric oxide in its turn quickly converts itself into nitric peroxide, by the abstraction of additional oxygen from the air that is constantly entering the chamber through the burners. Again, in the presence of moisture which is supplied by a jet of steam from the boiler, C, sulphurous acid readily deprives the nitric peroxide of oxygen, and thus forms more sulphuric acid, and again liberates nitric oxide; which is ready once more to seize upon the oxygen of the air, and would continue so acting and reacting *ad infinitum*, were it not carried forward and out by the chimney.

The chamber is an immense box or room of lead, bound together with a strong framework of timber, and generally raised on arches several feet above the ground. Chambers vary in size from 60 to 140 feet in length, and from 20 to 40 feet in width and height. Curtains of lead proceeding alternately from the bottom to near the top, and *vice versâ*, are very frequently used; they serve to retard the progress of the gases, and thus ensure the transformations desired. The floor of the chamber is covered with water, into which the sulphuric acid falls as it is formed; and when this solution attains a certain strength it is tapped off for concentration. When the gases reach the chimney, on account of the reactions of the nitrous compounds already explained, a large amount of nitrous acid would not only be wasted, but would also be deleterious to the neighbourhood, were steps for its recovery not adopted. This recovery is usually effected by means of a tower filled with coke, E, down which a constant stream of strong sulphuric acid trickles, the acid absorbing the nitrous fumes in their way upwards. Instead of a single chamber, curtained off or not as the case may be, sometimes three or five distinct chambers, connected by pipes, are employed, those communicating directly with the burners being termed working chambers, and the others receiving chambers, the last either acting as or communicating with a condenser or chimney.

When iron pyrites is used as the source of sulphurous acid suitable burners are used. In England these are arched chambers about four feet each way, on plan with furnace-bars placed a little above the ground. There are also the necessary doors and air-holes. The pyrites is broken into pieces and spread in layers on the bars, which are previously heated to redness, and the heat evolved by the burning sulphur is thereafter sufficient for the fresh charges. The exhausted ore is frequently sufficiently rich in copper for its extraction; indeed, when there is as little as 2½ per cent. present in pyrites it is now recovered. In consequence of strong sulphuric acid absorbing both sulphurous acid and nitrous acid, the acid requires to be drained off from the chamber while the solution is comparatively weak, at which strength—viz. of a specific gravity of about 1·4—it is used for some purposes in the arts under the name of 'Chamber Acid.' This is concentrated by evaporating in lead pans, D, till it reaches the specific gravity of 1·6, then boiling in a platinum retort, on which strong acid does not act, even at high heat, or in large flint-glass retorts. In the process introduced in 1859 by Mr Glover the gaseous sulphuric acid from the sulphur or pyrites burners is not conducted direct to the lead chamber, but is first passed through a Glover's or denitrating tower, and there purified of nitrogen compounds, which are saved for use in the lead chamber.

The manufacture of sulphuric acid is a very extensive industry; immense quantities of it being consumed in the manufacture of Soda (q.v.), in that of bleaching-powder, in calico-printing and dyeing, and in fact in most chemical operations both in the manufactory and the laboratory. In medicine a dilute sulphuric acid, formed by gradually mixing the strong purified acid with water, or aromatic sulphuric acid (known also as *elixir of vitriol*), prepared by mixing sulphuric acid, rectified spirit, tincture of ginger, and spirit of cinnamon, are almost always employed. In doses of from ten to thirty minims, properly diluted, these preparations exert a strong astringent power, and are serviceable in all forms of passive hæmorrhages, and in checking inordinate discharges when they arise from debility. Poisoning with this and other irritant acids is noticed at Poison, Vol. VIII. p. 265.

There are works on the manufacture by Smith (1873), Lock (1879), and Lunge (new ed. 1891).

Sulphuric Anhydride, SO_3, is obtained by distilling fuming Nordhausen sulphuric acid, a fibrous mass of silky crystals being deposited in the receiver. It may also be prepared by the distillation of anhydrous bisulphate of soda. It is a tough solid, melting at 65° (18·3° C.), and possessing none of the properties of an acid, not even affecting the skin. In contact with moisture much heat is developed, and it then possesses the corrosive properties of sulphuric acid.

Sulphuric Ether. See Ether.

Sulphurous Acid. See Sulphur, p. 795.

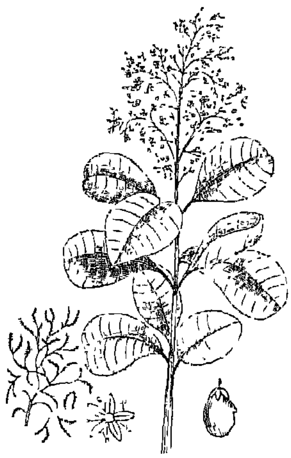
Sulpicians, an order of priests for training young men for the church, founded in 1645, and named from the church of St Sulpice (q.v.) in Paris.

Sulpicius Severus (363–410), a Christian historian, born in Aquitaine, who wrote a *Historia Sacra* from the Creation downwards, and a Life of St Martin (q.v.) of Tours.

Sultan (Arab., Turkish, and Persian *Sultân*), a Mohammedan ruling prince or monarch, as of Morocco or Zanzibar; especially used of the Sultan of Turkey, who calls himself Sultan of Sultans. The name of *Sultana* is given to the mother, wife, or daughter of a sultan. The old English form of the word was Soldan or Sowdan.

Sulu Islands, an archipelago stretching from Borneo north-eastwards to the Philippines, in the south-east of Asia. The group, numbering 162 islands in all, most of them mountainous and all covered with luxuriant vegetation, has a total area of 948 sq. m. and a total pop. of 75,000. The inhabitants, Malays by race and Mohammedans by religion, were the terror of the neighbouring seas, owing to their bold piracy, until the Spaniards conquered them in 1876; they now direct their energies chiefly to the collection of edible birds'-nests and pearl-fishing, what trade there is being principally in the hands of Chinese. The town of Sulu has been fortified by the Spaniards since they captured it.

Sumach, Sumac, or Shumack (*Rhus*), a genus of small trees and shrubs of the natural order Anacardiaceæ; having small inconspicuous flowers in panicles or in corymbs, and the fruit a small, nearly dry drupe. The species are numerous, diffused over almost all parts of the world, except its coldest regions and Australia; some of them are useful in the arts and in medicine, and some are remarkable for their poisonous properties. Venetian Sumach (*R. cotinus*), known also as Wig Sumach, or Wig Tree, is a native of the south of Europe and west of Asia, and is often planted in Britain as an ornamental shrub. It has simple leaves, and hairy corymbs of fruit, which have a sort of resemblance to periwigs. The twigs and leaves dye yellow (see FUSTIC), and are used in tanning. The bark has been used as a substitute for Peruvian Bark. The seed resembles the almond in flavour. The very acid fruit of the Sicilian or Elm-leaved Sumach (*R. coriaria*)—a native of the countries around the Mediterranean, with pinnate leaves, not unfrequent in British shrubberies—has been used as a condiment, and the seeds and the leaves medicinally as tonic and cooling. This species is also used for tanning and dyeing. Similar to this in its properties is the Virginian Sumach, or Stag's-horn Sumach (*R. typhina*), a native of eastern North America, and common in British shrubberies, which has the branches curiously crooked, and covered when young with a soft velvety down. It has pinnate leaves, with numerous leaflets, and is valuable as an astringent and refrigerant. The milky juice which exudes from incisions made in the bark affords a varnish. The flowers supply abundance of honey. The Smooth-leaved Sumach (*R. glabra*), a very similar species, also North American, has very acid leaves, and this species is sometimes troublesome as a weed. Of the acrid and poisonous species the most important is the Poison Ivy (*R. toxicodendron*) of North America, a shrub from 1 to 3 feet high (when it is also called Poison Oak), or a climber, with leaves of three leaflets, and a milky juice, which becomes black on exposure to air. The leaves have been used in medicine as a stimulant of the nervous system. Similar to this in properties is the Poison Sumach (*R. venenata*), with from 7 to 13 leaflets, also known as Poison Elder and Swamp Dogwood, and other North American species, the juice of which is very acrid; even the emanations are injurious to some persons, who, from standing close to these plants, or from handling them, experience a cutaneous eruption with violent itching. The Varnish Sumach (*R. vernicifera*), a native of Japan and Nepal, yields a varnish much used in Japan for lacquer-work. *R. metopium* yields in great abundance a gummy resin, which in a pure state is yellow in colour, and of a hard brittle consistence. *R. pumila* is regarded as one of the most poisonous of the genus. *R. succedanea*, a native of Japan, yields a fleshy fruit containing a nut, which yields an oil that is made into candles.—The name Tanners' Sumach is given to *Coriaria myrtifolia*, a shrub of the south of Europe.



Sumach (*Rhus cotinus*), showing leaves, flowers, and fruit.

Sumatra (so called probably from the ancient town of Samudera in the north) is after Borneo the largest island of the East Indian Archipelago or Indonesia, having an area not much less than that of Spain, calculated on very imperfect data at 165,600 sq. m. (or, including the numerous and important islands off the coasts, 170,780 miles). Towards the middle it is crossed lengthwise by the equator, and it extends from 5° 40′ N. lat. to 5° 59′ S. lat., and from 95° 16′ to 106° 3·45′ E. long. The greatest length is 1115 miles, the greatest breadth 275. An imposing mountain-system—the Bukit Barisan, or Chain Mountains, consisting of several more or less parallel ranges (7000 to 10,000 feet high), with intervening plateaus and valleys—forms the framework of the island, which has a bold and frequently precipitous coast towards the west, but has been carried eastward by the formation of vast expanses of alluvial ground. This striking contrast between east and west has been produced in part by the difference between exposure to the full force of the Indian Ocean and the shelter afforded by the Malacca Peninsula and the other islands of the archipelago. Slates and clay-schists of high antiquity, with granite not so frequently visible, form the original kernel of Sumatra, which has been subsequently modified by Carboniferous strata, long afterwards by Tertiary breccias, sandstones, marls, and coal-beds, and still further by very extensive Post-tertiary deposits. Volcanoes have played a large part in embossing the surface. Of the numerous cones along the Bukit Barisan ranges some seven or eight are still active, including Indrapura (the culminating peak of the island, 11,800 feet), Merapi (the most restless), Pasaman or Mount Ophir (which broke out in 1891), &c. In 1883 the southern end of the island was involved in the Krakatoa eruption. The mountain-lakes, which are characteristic of the island, are largely of volcanic, and more especially of craterial origin; of these the most important are the Singkarah, the Korintji, the Ranau, and the Tobah. Towards the east the rivers of Sumatra are of necessity short and rapid, but several of the westward streams, the Rokan, Siak, Indragiri, Jambi, and Palembang or Musi, grow to imposing rivers in their passage through the plains. They are fed by an abundant rainfall; the average precipitation at Deli, for example, is 83 inches per annum. The clouds descend much lower than in other islands of the archipelago. The division of the seasons is of course quite opposite in the two halves of the island lying respectively north and south of the equator. Hailstorms are not infrequent in the higher regions. The Sumatra flora is exceptionally rich. Junghuhn's paradox that an ape could traverse the island from north to south without descending to the ground is almost literally true. Vast but too rapidly diminishing areas of the mountain regions are covered with virgin forest, a striking contrast to the vast prairies of alang (or lalang), that vigorous grass which seizes on every clearing not occupied by human industry. Though it only explored a small portion of the western side of the island, the Dutch expedition of 1877-79 collected 400 varieties of timber. The vegetation-contours of the island descend much lower than those of Java. In Java, for instance, the oaks do not grow below an altitude of 4500 feet; in western Sumatra they come down to within 500 or even 100 feet of sea-level. The flora of the east coast is almost entirely unexplored. Rice, sugar (from cane and the Arenga palm), coffee, pepper, cocoa-nuts, sago, maize, sweet potatoes, yams are among the principal cultivated products. In recent years the tobacco of the Deli district, grown by Dutch planters with Chinese coolie labour, has become favourably known both in European and American markets. Of several minerals existing in average quantities in the island only two, gold and coal, are worked to any economical result, the latter especially at Ombilin, which was united with the west coast by railway in 1891.

The Sumatran fauna is of peculiar scientific interest. Of the 112 mammals known to exist in the island (19 more than those in the larger island of Borneo) 45 are common to Borneo and 39 to Java. The birds are in the main Bornean, and the same is true of the snakes (44 species). The Bornean forms, however, are almost entirely confined to the eastern side of the island; as soon as the naturalist crosses the Barisan Mountains he finds himself in a new region. The Orang-outang (of limited range and not abundant) and the *bru* (Malay name) or Meester Kees (Dutch), employed by the natives to gather their cocoa-nuts, are the most noteworthy of the numerous apes. The true tiger, the bruang or Malay bear, the much-hunted rusa deer, the dainty kanchil deer, the Malay hog, the tapir, the two-horned Sumatran rhinoceros, and the Sumatran elephant are characteristic forms. Among the commonest birds are Argus pheasants, hornbills, goatsuckers, and grakles (one species of the latter largely kept in cages for their parrot-like powers of speech). Both the python (15 to 20 feet long) and the cobra are of frequent occurrence, and the crocodile swarms towards the coast and ascends the rivers as far as the foot of the mountains. As an indication of the extraordinary variety of insect life, 250 species of spiders have been discovered since 1858.

Sumatra is peopled in the main by tribes of the Malay stock, differing very markedly, however, in degree of civilisation, custom, and language. An earlier non-Malay element is more or less distinctly represented. The Kubus, a savage forest-dwelling race, the Battas (q.v.) or Battah—now one of the best-known and ethnographically most interesting tribes—and the Redjangers may be singled out from a host of others. Hindu influences, which have left their mark in ruins of temples, religious customs, language, alphabets, &c., began to tell on Sumatra at a period prior to the 7th century. In the 13th Mohammedanism was introduced. The island became known in 1508 to Europeans through the Portuguese Lopez de Figuera, whose fellow-countrymen were not long in founding trading stations on the coasts. The Portuguese were ousted by the Dutch towards the close of the 16th century. Begun in 1620 by their East India Company, the permanent Dutch occupation was not completely carried out round the coast till 1881, and much of the interior is still semi-independent and unexplored. The Dutch possessions were in the hands of the British between 1811 and 1816, and portions down till 1825. The residency of the East Coast was established in 1873; the government of the West Coast in 1819; and the residencies of Bencoolen, Palembang, and Lampong respectively in 1824, 1825, and 1857. Atjeh, Achin, or Atcheen (q.v.), only subdued after a long war (1875-79) and not yet pacified in 1892, was formed into a government in 1881. The total population of Sumatra and the adjacent islands is estimated at 3,572,000 (Achin, 445,000; west coast, 1,457,500; East Coast, 450,000; Bencoolen, 151,800, &c.). Among the more important centres of population are Padang (150,000), Achin (10,000), Bencoolen (12,000), and Palembang (43,000).

For literature on Sumatra, see *Aardrijkskundig Woordenboek van Ned. Ind.* (1869); Kan in *Tijdschrift van het K. Ned. Aard. Gen.* (1889). See especially Marsden's classical work, *The History of the Island of Sumatra* (1783); the Memoir of Sir Stamford Raffles; Veth, *Midden-Sumatra* (1882); Kielstra, *Atjeh Oorlog* (1885-86); Wallace, *Indian Archipelago;* Forbes, *A Naturalist's Wanderings in the E. Archipelago* (1885); Hagen, 'Die Pflanzen- und Tierwelt von Deli auf der Ostküste Sumatras,' in *Tijds. van het N. Aard. Gen.* (1890). Recent explorations are those of Schouw-Santvoort (1877), Brenner-Felsach (1887), and Izermann (1891).

Sumbawa, one of the chain of the Sunda Islands to the east of Java, lies between Lombok (on the west) and Flores (on the east). Area, 5192 sq. m.; pop. about 150,000, all Malays and Mohammedans. They are divided between four native rulers, who owe allegiance to the Dutch governor of Celebes. The islands are mountainous but fertile, and yield rice, tobacco, cotton, sandalwood, &c. In 1815 an eruption of Tambora, the loftiest peak on the island, whereby the altitude was decreased from 14,000 to 7670 feet, depopulated the kingdoms of Tambora and Papekat, 12,000 lives being lost, and great damage done to the whole island by the ashes. Another eruption took place in 1836, and one of another peak, Gunong Api, in 1860, though with little loss.

Sumir. See BABYLONIA, Vol. I. p. 631.

Summer Isles, a group of twenty rocky islets off the west coast of Scotland, near the entrance of Loch Broom, an inlet in the north-west of Ross-shire. The largest, Tanera, measuring 1¾ by 1½ mile, rises 406 feet, and has 119 inhabitants.

Summons, in English law, means generally a writ or order directed to a party to appear and answer some complaint before a court or judge. All actions in the High Court now begin with the issue of a writ of summons. A summons is usually the first step in summary proceedings before magistrates. In Scotland the first writ in an action is called a summons; and the term is also in use in the colonies and in the United States.

Sumner, CHARLES, American statesman, was born in Boston, January 6, 1811. The founder of the family in America was William Sumner, a native of Oxfordshire in England, who settled in Massachusetts about 1635. Charles Pinckney Sumner, of whose nine children Charles and his twin-sister Matilda were the eldest born, held the post of sheriff of Suffolk county from 1825 till shortly before his death in 1839, and was highly respected for his probity and independent spirit, despite his stiff and formal manners and his outspoken anti-slavery sentiments at a time when such opinions were generally unpopular and were rarely expressed by persons in official station. Educated at the Boston Latin School and at Harvard College, where he graduated in 1830, Charles Sumner entered the law-school in the following year, and in 1834 was admitted to the bar. An enthusiastic student of the principles of law, he had little taste for the ordinary routine of office work, and hence, though occasionally engaged in important cases, he failed to secure a remunerative practice or to acquire reputation as a pleader. He found more congenial employment as a lecturer on legal topics and a contributor to law journals and compilations. In private life he was greatly esteemed for his sincerity and earnestness, his general cultivation, his stainless character, and his cheerful and kindly demeanour, though too devoid of humour, wit, and playful fancy to become a favourite in ordinary social circles. In December 1837 he went to Europe, where he remained till May 1840, pursuing with his habitual assiduity the study of jurisprudence at the Sorbonne and elsewhere, widening the general range of his knowledge, and cultivating the acquaintance, especially in England, of the most eminent men, of whom his letters at this period, published since his death, give many graphic sketches and lively anecdotes. On his return to Boston he resumed his professional practice, but with even less liking for the drudgery of its details than he had before evinced. Abstract discussion had stronger attractions for him, and he first came into prominence by a civic oration, on July 4, 1845, which, under the title of 'The True Grandeur

Copyright 1892 in U.S
by J. B. Lippincott
Company.

of Nations,' was simply a vehement denunciation of war, as 'utterly and irreconcilably inconsistent with true greatness.'

It was because the current of events was then bringing to the front a subject involving the deepest moral considerations that Charles Sumner was drawn into the vortex of political life. A member of the Whig party by descent and associations, he took but a languid interest in politics until the threatened extensions of negro slavery over newly-acquired territory awakened a spirit of resistance in the free states. Despite the efforts to stifle agitation by party leaders and all who feared for the results, the growth and preponderance of the slave power, with the foundations on which it rested, became the absorbing question of the day, entering like a wedge into established political combinations and thrusting aside all other issues. Sumner was at one with the Abolitionists in asserting the inherent and total sinfulness of slavery; but unlike them he maintained that the constitution did not recognise property in man, and that slavery, a purely sectional institution, could be combated in the political arena, and so crippled by legislation that it would necessarily dwindle and become extinct. In 1848 he joined with others holding similar views in the formation of the Free Soil (q.v.) party, in which his abilities, learning, high character, and social standing gave him a prominence which he cannot be said to have sought by any purely ambitious efforts. Nominated for congress in the same year, he was easily defeated by the Whig candidate, R. C. Winthrop; but in April 1851, after a protracted contest, he was elected to the national senate as the successor of Daniel Webster, by the combined Free Soil and Democratic votes of the Massachusetts legislature. The post thus gained he continued to hold during the remainder of his life, being re-elected in 1857, 1863, and 1869. At the outset he stood alone in the senate as the uncompromising opponent of slavery, and his elaborately prepared speeches, characterised alike by their studied array of facts and arguments and their bold denunciatory tone, excited universal attention, and were perhaps equally effective in winning support in one section and inflaming hostility in the other. The latter spirit found vent in an act which produced a more startling and profound impression throughout the northern states than any speech could have made. On the 22d May 1856, while sitting at his desk in the senate chamber after an adjournment, Sumner was suddenly assaulted by Preston S. Brooks, a member of congress from South Carolina, and by repeated blows on the head with a heavy cane prostrated on the floor in a state of insensibility. His injuries were in fact so severe as to incapacitate him for public life during nearly four years, while his vacant chair was pointed to as the most eloquent reminder of the violent and lawless animosity against which the advocates of freedom must prepare to contend. He resumed his seat at the close of 1859, and in June 1860 delivered a speech on the question of the admission of Kansas as a free state, which he published under the title of *The Barbarism of Slavery*.

But the predestined course of events no longer needed any impulse from oratory, and the attempts to arrest it by conciliatory offers, in which Sumner naturally took no part, only pointed more plainly to the inevitable collision. The secession of the southern states left the Republican party in full control of both houses of congress, and in March 1861 Sumner was elected chairman of the senate committee on foreign affairs. His interest in domestic affairs was still centred on those in regard to which moral principles could be adduced as the proper basis of political action. He was urgent for the emancipation of the slaves, and not less strenuous, after this had been secured, in obtaining for the coloured race the fullest civil and political equality with the whites. He supported the impeachment of President Johnson, regarding it as a continuation of the struggle for the overthrow of slavery, and he was foremost in opposing President Grant's project for the acquisition of San Domingo, on the ground that the assent of Baez, the president of that republic, had been given in opposition to the wish of the inhabitants. His conduct on this occasion led to his exclusion in 1871 from the chairmanship of the committee on foreign relations, and his continuous and acrimonious censures on Grant's administration brought about a rupture with the leading politicians of the Republican party which was rendered complete by his support of Greeley as candidate for the presidency in 1872. But, although the result of the election left him in the ranks of a discontented minority, his course had been too evidently dictated by principle to allow of his sinking in esteem with the mass of the party, and the breach was gradually closing when his death, at Washington, on the 11th March 1874, obliterated all asperities, and left only the remembrance of his great services and distinguished career.

Sumner's position in the field of politics was in some respects unique. From first to last he was an independent rather than a partisan. Nature had given him neither the submissive temper of the follower nor the tact, the shrewdness, the persuasive eloquence, and the skill in the management of men and of affairs which are the requisites of leadership. Expediency had no place in his thoughts, flexibility in his disposition, or suavity in his methods or language. Had it been otherwise he might, on the death of Lincoln, have succeeded to the highest place in the national confidence and regard. For his position was a commanding one, owing to his unimpeachable integrity, his unflinching courage, his singleness of purpose and consistency of action, his freedom from every suspicion of intrigue or self-seeking, and his identification both as a victim and a victor with the cause to which he had devoted all his energy and talents. In person he was tall and well proportioned, and, though his features were rugged, the expression of his countenance was engaging. His speeches lacked the charm of spontaneous eloquence, but they were effective as essays or lectures, and furnished his supporters with an arsenal of arguments and illustrations. That his frequent virulence in public debate sprang from no bitterness of spirit is attested by his freedom from vindictiveness, his cordiality in private intercourse, and the warmth and fidelity of his friendships. His nature was too open to admit of misconstruction, and the poet Longfellow, with whom he lived in intimacy, described him as the whitest soul he had ever known.

Sumner's works fill fifteen volumes (Boston, 1870-79). See his *Memoirs and Letters* by Pierce (2 vols. 1877), and shorter Lives by Lester (1874) and Chaplin (1874).

Sumner, JOHN BIRD, Archbishop of Canterbury, was born in 1780, and educated at Eton and Cambridge. Successively rector of Mapledurham (1818), Bishop of Chester (1828), and Primate of all England (1848), he was distinguished for his conciliatory disposition and moderate views, and wrote works on *Apostolical Preaching*, *The Moral Attributes of the Creator*, and *Evidences of Christianity*. He died 6th September 1862.—His brother, CHARLES RICHARD (1790-1874), was Bishop of Winchester, and his Life was published in 1876.

Sumptuary Laws (Lat. *sumtus*, 'expense'), laws passed to prevent extravagance in banquets, dress, and private expenditure. They abound in ancient legislation. The Locrian legislator, Zaleucus, 450 B.C., ordained that nobody should drink undiluted wine; and in Solon's code there were many sumptuary enactments. At an early period in Roman history the Censors, to whom was entrusted the superintendence of public and private morality, punished with the *notatio censoria* all persons guilty of luxurious living; but as the love of luxury grew with the increase of wealth and foreign conquest various legislative enactments were passed with the object of restraining it. The Lex Orchia, 187 B.C., limited the number of guests to be present at a feast; the Lex Fannia, 161 B.C., regulated the cost of entertainments. There were also the Lex Didia, Lucretia, Cornelia, Æmilia, and others, most of them passed in consequence of the practical disregard of the similar laws that had preceded them; but they all seem to have been habitually transgressed in the later times of the Republic. Julius Cæsar, Augustus, and other rulers also made laws against luxury.

Sumptuary laws were in great favour in the legislation of England from the time of Edward II. down to the Reformation. Statute 10 Edward III. chap. 3 narrates that 'through the excessive and over-many costly meats which the people of this realm have used more than elsewhere many mischiefs have happened; for the great men by these excesses have been sore grieved, and the lesser people, who only endeavour to imitate the great ones in such sorts of meat, are much impoverished, whereby they are not able to aid themselves, nor their liege lord, in time of need as they ought, and many other evils have happened as well to their souls as their bodies;' and enacts that no man, of whatever condition or estate, shall be allowed more than two courses at dinner or supper, or more than two kinds of food in each course, except on the principal festivals of the year, when three courses at the utmost are to be allowed. All who did not enjoy a free estate of £100 per annum were prohibited from wearing furs, skins, or silk, and the use of foreign cloth was allowed to the royal family alone. Act 37 Edward III. declares that the outrageous and excessive apparel of divers people against their estate and degree is the destruction and impoverishment of the land, and prescribes the apparel of the various classes into which it distributes the people; it goes no higher than knights, but there are minute regulations for the clothing of women and children. This statute, however, was repealed the next year. In France there were sumptuary laws as old as Charlemagne, prohibiting or taxing the use of furs; but the first extensive attempt to restrict extravagance in dress was under Philip IV. By an edict of Charles VI. no one was allowed to exceed a soup and two dishes at dinner. Frederick the Great and other German princes endeavoured to suppress the use of coffee as a harmful luxury. Sumptuary laws continued to be introduced in England in the 16th, in France as late as the 17th century; and burial in woollen, prescribed by English law from 1678 till 1815, was akin to them, though its primary object was to lessen the importation of linen. The Scottish parliament attempted to regulate the dress of the ladies, to save the purses of the 'puir gentlemen their husbands and fathers;' and statutes were passed against superfluous banqueting, and the inordinate use of foreign spices 'brocht from the pairts beyond sea, and sauld at dear prices to monie folk that are very unabill to sustain that coaste.' Neither in England, Scotland, nor France do these laws appear to have been practically observed to any great extent: in fact, the kings of France and England contributed far more, by their love of pageantry, to excite a taste for luxury among their subjects than by their ordinances to repress it. Froude has suggested that such statutes may have been regarded, at the time when they were issued, rather as authoritative declarations of what wise and good men considered right than as laws to which obedience could be enforced. Enactments of this kind have long been considered to be opposed to the principles of political economy. Most of the English sumptuary laws were repealed by 1 James I. chap. 25; but regulations of a similar kind survive in the university statutes of Oxford and Cambridge. There is a trace of the same principle in the present-day taxation of luxuries—wine and spirits, tobacco, tea, and coffee (though mainly with a view to regulating the incidence of the tax), and in the duties on male servants, armorial bearings, &c. And one reason sometimes urged for the suppression of the liquor traffic is the diminution thereby to be effected in wanton waste and pernicious luxury. In Montenegro strong laws were passed in 1883 against gloves, umbrellas, and non-national costumes.

Sumter, Fort (named after General Thomas Sumter, 1734–1832, an active partisan leader of the revolutionary war), an American fort associated with both the beginning and the end of the civil war, was built of brick, in the form of a truncated pentagon 38 feet high, on a shoal, partly artificial, in Charleston Harbour, 3½ miles from the city. On the secession of South Carolina in December 1860, Major Anderson, in command of the defences of the harbour, abandoned the other forts, and occupied Fort Sumter, mounting sixty-two guns, with a garrison of some eighty men. The attack on the fort was opened by General Beauregard on April 12, 1861, and it surrendered on the 14th: this event marked the beginning of the war. The Confederates strengthened it, and added ten guns and four mortars. In April 1863 an attack by a fleet of monitors failed. In July batteries were erected on Morris Island, about 4000 yards off, from which in a week 5000 projectiles, weighing from 100 to 300 lb., were hurled against the fort; at the end of that time it was silenced and in part demolished. Yet the garrison held on amid the ruins, and in September beat off a naval attack; and in spite of a forty days' bombardment in October–December 1863, and for still longer in July and August 1864, it was not till after the evacuation of Charleston itself, owing to the operations of General Sherman, that the garrison retired, and the United States flag was again raised, April 14, 1865; an event soon followed by the evacuation of Richmond and the Confederate surrender.

Sumy, a town of Russia, 125 miles by rail NW. of Kharkoff. Pop. 15,831.

Sun, the star which warms, governs, and illuminates the earth and the other bodies forming the Solar System. By the patient efforts of astronomers and physicists a vast body of knowledge, of which here we can but give the outline, has been gained regarding it. For convenience we condense such of this information as admits of the treatment into the subjoined table.

Equatorial horizontal parallax		8″·794
Mean distance		92,965,000 miles
Diameter		867,000 miles
Diameter (apparent angular)		Max. 32′ 36″·4 Min. 31′ 32″·0
Mass	Earth's as unity	330,000
Density		0·25
Volume		1,306,000
Force of gravity at surface		27·6
Period of rotation on axis		25 days 7 hours 48 minutes
Inclination of axis to plane of ecliptic (1850)		82° 45′
Velocity of rotation at equator		4407 miles per hour
Longitude of node of equator (1850)		73° 40′
Surface in square miles		2,283,021,400,000

Energy radiated from each square foot of this surface (Stokes) = 12,000 horse-power.

Early observations of the sun were necessarily confined to records of its motions and eclipses, of which a very fair mastery was gained even in Chaldæan and Egyptian times, as well as early in the history of China (see ASTRONOMY). The apparent motions of the sun, determining as they do what part of our world shall at any time receive his heat and light more or less abundantly, are so regular and so important to our life that they naturally give us our principal time measures (see DAY, YEAR, SEASONS). For long the observation of these formed perhaps the chief part of astronomy. But when Copernicus showed that the sun was really the centre of our system, and Galileo discovered the moons of Jupiter, the idea of a community of nature between the sun and our world—the earth circling around the sun as the moons around Jupiter—began to take firm root in men's minds. Newton's extension of the law of gravitation to the heavenly bodies greatly aided this process. The idea that the sun shone because composed of mysterious fiery elements faded away, and men began to ask after its real constitution, and seek the secret of its stores of energy. But to answer this question required much preliminary investigation, and to trace this, so far as it has gone, is to track some of the best and purest triumphs of human patience and skill.

(1) *The sun's distance* was the first problem to be attacked. In ancient times Aristarchus of Samos tried to solve this by measuring the angle between the sun and moon when the latter was in her quarters (see MOON). This method, even if accurately followed, would give no absolute measure, but only the *relation* between the distances of the sun and moon. From his attempts Aristarchus concluded the sun to be eighteen times as far from us as the moon. In reality his method is one which can give no accurate result, though it represents a great step in astronomical investigation. As instruments improved, and especially when the telescope was invented, new measures were made, only to result in the conviction that the sun was so far away that accurately to measure its distance appeared impossible. The distance of celestial objects is found by the measurement of their *Parallax* (q.v.). If an observer changes his own position, all the objects around him appear also to shift their relative positions, those nearer shift more than distant ones, and by the amount of shift for a known change of the observer's place their distance may be calculated. The greater the distance between the observer's two positions the greater (and therefore more easily measurable) is the apparent shift of the objects before him. It was found ere long that no change of place possible on our small earth, 8000 miles in diameter, was sufficient to produce a *definitely measurable* change in the sun's position on the celestial sphere. By an opposition of Mars (see below) observed in 1672 by Richer at Cayenne and Cassini at Paris this angular change of place (or parallax) was given at 9″·5 = a distance of 87,000,000 miles. Flamsteed, by the same method, reached a parallax of 10″ = 81,700,000 miles, Picard's measure was parallax 20″ = 41,000,000 miles, and Lahire's 136,000,000 miles.

At last, in 1716, the English astronomer Halley proposed a method of employing the transits of Venus. Accordingly the transits of 1761 and 1769 were observed in a variety of places; but the results at first deduced were discordant and unsatisfactory, until in 1824 the German astronomer Encke 'discussed' the observations of 1769, and arrived at a distance of about 95,300,000 miles; and this number held its place in books of astronomy for a good many years. A transit can occur only when the planet is in or near one of her nodes at the time of inferior conjunction, so as to be in a line between the earth and the sun. The coincidence of these two conditions follows a rather complex law. There are usually two transits within eight years of one another, and then a lapse of 105 or 122 years, when another couple of transits occur, with eight years between them. The transit of 1874 had for its successor that of 1882, and there will not be another until June 2004. The way in which a transit is turned to account may be understood by the help of fig. 1, where E represents the earth, V Venus, and S the sun. It is to be premised that the *relative* distances of the planets from the sun are well known. Their periodic times can be observed with accuracy, and from these by Kepler's (q.v.) Law we can deduce the *proportions* of the distances, but not the distances themselves. It is thus known that, if the distance of the earth from the sun is taken as 100, that of Venus is 72. In the fig., then, AV is 28, or about one-third of V*a* or V*b*. An observer at a station, A, on the northern part of the earth will see the planet projected on the sun as at *a*, while a southern observer will see it at *b*. The distance of the sun from Venus being about three times her distance from the earth, it is obvious that the distance *ab* will be three times the distance AB; and it is a great advantage to have the stations A, B, as far apart as possible, as the interval *ab* is thus increased, and its measurement rendered more accurate.

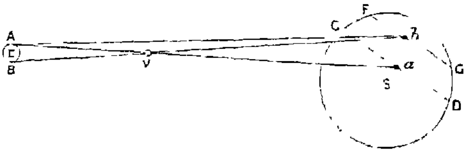


Fig. 1.

But how is it measured? For each observer sees only one of the spots, and does not know where the other is; and there are no permanent marks on the sun's surface to guide us. The difficulty is got over in the following way. Each observer notes the exact duration of the transit—i.e. the time the spot takes to travel from C to D, or from F to G. Now as we know the rate of Venus' motion in her orbit, this gives us the length of the lines CD and FG in minutes and seconds of arc. Knowing then the angular diameter of the sun (32′) and the lengths of two chords CD and FG, we can easily, by the properties of the circle, find the distance *ab* between them. This gives us the angle *a*A*b*. In the triangle AV*b*, then, we know the angle at A and the proportion of the sides AV and V*b*, and from that we can find the angle A*b*V and A*b*B. Now this is the quantity sought, being the parallax of the sun as seen from two stations on the earth. Whatever the distance AB actually is, the angle is reduced to correspond to a distance equal to the earth's semi-diameter. The parallax deduced by Encke, as above referred to, was only 8″·5776. The advantage of this roundabout procedure is that a comparatively large angle (*a*A*b*) is measured in order to deduce from it a smaller (A*b*B), so that any error in the measurement is diminished in the result.

Meanwhile during the later part of the 18th century efforts had been made by Dr Stewart of Edinburgh (1763) and Mayer of Göttingen to determine the sun's distance by the lunar 'parallactic inequality' (see MOON). These amounted to little until Laplace (q.v.) solved the problem and gave a result hardly different from Encke's. In 1854 and 1858, however, Hansen and Leverrier found reason to doubt its correctness. A favourable opposition of Mars in 1862, observed by Stone and Winnecke, justified their doubts, fixing the distance somewhere between 91 and 92½ million miles. The method employed so far resembled that of the transits of Venus that it depended on measuring the distance of a nearer object than the sun—viz. the planet Mars in opposition. From this, the *proportions* of the planetary distances from the sun being accurately known, the solar distance was easily calculated.

Meanwhile, by a most ingenious method, another measure of this was obtained. Romer (1675), Delambre (1792), and Glasenapp (1874) had ascertained (the last with great accuracy) by observation of Jupiter's Satellites (q.v.) that light takes 500·84 seconds to cross the earth's orbit from side to side (Glasenapp's result). Also the amount of the Aberration of Light (q.v.) had been carefully measured If the velocity of light were known these would afford a means of estimating the sun's distance. This velocity was measured by Fizeau and Foucault in 1862 The result confirmed the later and smaller estimate of solar distance given above. A rediscussion of the transit observations of 1769 by Powalky (1864) and Stone (1868) also confirmed it.

The transit of Venus in 1874 was impatiently awaited, as with modern instruments and methods a final settlement of the question was anticipated. But, although about eighty posts of observation were provided all over the world and many observers carefully trained, little or no progress was made Atmospheric effects and photographic defects left an uncertainty estimated by Professor Harkness of Washington, D.C, at 1½ million miles.

Dr Gill in 1877 observed a favourable opposition of Mars, which gave a result of 93,080,000 miles. Observations of minor Planets (q.v.) were also utilised, and a number of expeditions sought a value from the transit of 1882. Michelson of the United States navy anew determined (in 1879) the velocity of light, and Professor Harkness used his value for it in another estimate. The amount of accuracy obtainable at present in such discussions may be judged by the various estimates given by the best authorities as follows: Professor Harkness, 92,365,000 miles; Professor Young, 92,885,000; Dr Ball, 93,000,000; Mr Stone, 92,000,000; M. Faye, 92,750,000. These various values will explain the varying estimates of the size, mass, density, &c. of the members of the solar system, as the sun's distance enters as a factor into all such calculations. The table at the beginning of this article is based on a solar parallax of 8″·794. In it the reader will find the results as to the sun's size, mass, density, and gravitational power of this conclusion as to his distance.

(2) *The sun's true motion in space* is ascertained from the comparison of observed stellar *proper motions* (see STARS). It is directed to a point on the line joining the stars π and μ Herculis. Its velocity is 1·623 radii of the earth's orbit *per annum.*

(3) The investigation of the *physical structure* and *chemical constitution* of the sun has been in modern times most successful. A long series of efforts by many workers has brought us to something like definite ideas as to its radiating power, which is a fundamental factor in this investigation (see HEAT). In 1837 Pouillet measured the amount of solar radiation. His result was that 1·76 *calories* per minute were received on every square centimetre of our earth's surface. Much of the sun's heat is absorbed by the terrestrial atmosphere. Hence Forbes ascended the Faulhorn in 1842 and obtained there the greater value of 2·85 calories. Violle on Mont Blanc in 1875 got 2·54. Professor Langley, probably the most accurate observer, gives very nearly 3·00. Computations of the sun's temperature in degrees Cent. have varied from a few hundreds to many millions. They are essentially misleading, as the condition of matter in the sun is not yet known sufficiently well to enable us to calculate its temperature from its radiation. We know, however, with certainty that the most refractory substances are vaporised long before the solar temperature is reached. And the sun's surface, seen by Langley through the then smoke-laden air of Pittsburgh, appeared 5300 times as bright as the molten metal in the fierce heat of a Bessemer converter. At the temperature indicated by this all known substances would exist as tenuous vapour, were the pressure bearing on them that of our terrestrial atmosphere. But in the interior of the sun, under pressures inconceivable to our minds, such vapours would behave very differently. Under such conditions the usual distinctions between solid, liquid, and gaseous forms of matter to which we are accustomed would be obliterated. In fact, how matter would behave in such a state science at present cannot tell. Of the sun's *surface*, however, we have learned much. According to the researches of Professor Rowland of Johns Hopkins University, Baltimore, in 1891, the following elements are present there. The list is in order, according to the number of spectral lines in the elements identified in the solar Spectrum (q.v.), iron coming first with more than 2000 lines identified, potassium last with 1 only. Iron, nickel, titanium, manganese, chromium, cobalt, carbon, vanadium, zirconium, cerium, calcium, scandium, neodymium, lanthanum, yttrium, niobium, molybdenum, palladium, magnesium, sodium, silicon, strontium, barium, aluminium, cadmium, rhodium, erbium, zinc, copper, silver, glucinum, germanium, tin, lead, potassium, and *possibly* iridium, osmium, platinum, ruthenium, tantalum, thorium, tungsten, uranium.

These as vapours form a layer upon the solar surface, which is in fact the solar atmosphere. Immediately *beneath* this is the *photosphere*, which marks to the eye the boundary of the sun's disc. *Above* this layer of vapours rise vast jets and clouds called variously *flames*, *prominences*, or *protuberances*. Above these again is the bright and curiously shaped solar *corona*, extending along the ecliptic, as once seen, to a distance of twelve solar diameters.

The *photosphere* presents to the telescope of low power an apparently even surface. Under higher powers its structure is seen to be complex. The whole surface is granulated, resembling a gravel heap seen from a little distance. These granules have been described as like 'willow leaves' and 'rice grains.' A multitude of minute dark points or pores, black in comparison with the granules, serve to emphasise their outline. This may be said to be the normal condition of the photosphere. There are always, however, some portions of the surface which show an indistinctness of granulation, sometimes so marked that they are named 'veiled spots.' Bands of this indistinctness in less marked form spread over the whole photosphere as a kind of network called by French observers the *réseau photosphérique*. They are continually in a state of fluctuation, and are most probably due to the currents of varying density in the solar atmosphere. The granules and spores are due to intense convection currents, the tops of ascending masses of vapour glowing white with the heat derived from the solar interior. These show as 'granules,' while the descending masses, having radiated their energy, return to be again heated below the surface, and in their descent show as the comparatively dark 'pores.' The appearance of the surface of a large mass of molten iron in an open mould gives a fair idea of this process. It must always be remembered, when vapour or gas is spoken of as at the sun's surface, that the enormous temperatures and pressures there prevailing, with the scale on which these must vary in short intervals of time, will make vapours behave much more like terrestrial solids than like gases as we know them. The impact of a small jet of solar 'vapour' would in fact be far more powerful than that of a projectile from a 100-ton gun. The rapidity of these convection currents must therefore be enormous, and a little careful watching soon shows that the whole solar surface is in a state of constant change.

In certain regions of the photosphere, between 6° and 35° solar latitude, both north and south of the solar equator, large black spots are frequently observed. In size these vary from 150,000 miles in largest diameter to small black dots approaching in appearance the 'pores.' The largest are easily seen by the naked eye when fog or dark glass protects it from the excessive solar glare. The activity of their producing cause is subject to a considerable variation. Schwabe of Dessau in 1843 announced the discovery of this important fact, giving about ten years as its period. Wolf in 1852 corrected this to 11·11 years. This is generally accepted as the *mean* period, but individual periods may vary from it considerably. The shortest periods are the most intense. There is an undoubted connection between this period and that of terrestrial magnetic phenomena. Auroræ and sun-spots wax and wane together, even in their smaller fluctuations. But the theory that sun-spots depend for their frequency on the influence and position of the planets has had to be abandoned. These spots usually have three well-marked areas, distinguished by their different degrees of blackness. The *penumbra* forms the outer border of the spot, and is only grayish compared with the general white of the solar surface. Within this is a much darker area called the *umbra*, and within this a still blacker spot, the *nucleus*. While sometimes persisting for months, spots frequently vanish or form in a few days, sometimes even in a few hours. They are the theatre of constant changes. Long filaments are often extended from the penumbra across the umbra, forming 'bridges.' In fact the whole penumbra appears filamentary in structure, being composed of the 'granules' drawn inwards from the edge by the force in the spot. Cyclonic movements have been observed in spots, but are not usual. The spot is most probably a cavity formed in the photosphere by the pressure of a vast descending mass of vapour. In spot latitudes, for some unknown reason, these masses collect in unusual size, not descending by the minute 'pores,' but requiring larger openings. Both spots and pores appear dark, not because the uncovered lower solar layers are cooler than those above, but because the cool masses of vapour pressing on them from above absorb their light, and prevent it reaching us. In reality their blackness or grayness is only such as compared with the intensely white photosphere. It is almost certain that these absorbing vapours are considerably cooler than the neighbouring surface. Great differences of pressure, as well as of temperature, exist in spots. Hence they are accompanied by (or accompany) great disturbances and fierce vapour currents. These affect even the earth, and cause simultaneous disturbances in our magnetic needles. White ridges (called *faculæ*) are raised in the neighbourhood of spots, indicating enormous pressures, and spreading often over a wide area of the solar surface. The spectra of sun-spots are most complex. Their meaning cannot yet be said to be fully understood. But they give certain evidence of vapour movements of enormous rapidity, and of pressures on a like scale. One example of this occurred in the great spot of June 1889, when a dark spectral line of iron was widened to five times its usual thickness, indicating an immense pressure. Displacements of lines from their normal position have also been observed, indicating vertical vapour movements at a velocity as high as 320 miles per second.

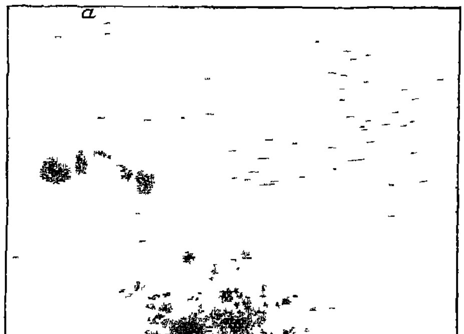

Fig. 2.—Sun-spots. From a photograph taken February 13, 1892, 9 hours 47 minutes. By permission of the Astronomer-royal. The centre of the sun's disc is at *a*.

During total solar eclipses certain solar phenomena become visible, which bear closely on the problem of the sun's physical condition. Chief among these are the *corona*, *prominences*, and *chromosphere*. The last (sometimes called the *sierra*) surrounds the sun completely. It consists of a layer of vapours covering the entire photosphere. Its depth varies at different times and in different parts, ranging from about 6000 to 2000 miles. As seen in eclipses it is of a beautiful rosy hue, and its surface, seen in profile at the edge of the solar disc, appears sharply jagged and broken into waves or spear-like jets of varied altitude. It consists chiefly of hydrogen and an element as yet unknown in our laboratories, called 'helium' (Gr. ἥλιος, 'the sun'). Sometimes heavier vapours, as of iron, calcium, titanium, magnesium, and others, are projected into it from the true solar atmosphere below. There is indeed no marked border between these groups of gases other than a fluctuating one due to their varied weight. The chromosphere rises often in local jets of rosy gas to an enormous altitude. These form the *prominences*, first recorded as seen at an eclipse by Captain Stannyan, who observed at Bern, Switzerland, the total eclipse of May 12, 1706. Since recorded at many Eclipses (q.v.), they are now daily studied through the open slit of the spectroscope, a method devised by Lockyer and Janssen in 1868, and improved in 1869 by Zöllner and Huggins. They form two well-marked classes, 'Cloud' and 'Flame' prominences. A 'Cloud' prominence resembles a terrestrial cloud, but, as seen by this method, of an indescribably delicate rosy hue, often connected by slender stems to the chromosphere. Such are relatively permanent, lasting usually a few days. 'Flame' prominences are eruptive, often connected with spots, and subject to violent changes even in the space of a few minutes. Delicate clouds of hydrogen are sometimes seen to form and disperse, *in situ*, in and close above the prominence region, exactly as clouds in our air, pointing out the fact that not even here is to be found the limit of matter ejected from or retained by the sun. The existence of the *corona* confirms this. Its appearance during a total eclipse may be gathered from fig. 3. Its shape varies, while yet a general agreement in form is preserved. In periods of sun-spot maximum it is more fully developed than at minimum periods, and differently shaped. At a spot minimum it is smaller and most developed towards the solar poles. At a maximum it gathers in great rays above the spot-region of the surface. As yet only to be studied during the short period of a total eclipse, the true nature of the corona is not determined. On one theory it has been thought to be like the Zodiacal Light (q.v.); on another it was supposed to consist of streams of meteorites; on yet another of cometary matter; and in a fourth it was regarded as chiefly terrestrial atmospheric glare. It is now generally admitted to consist of tenuous gas, hydrogen, and helium, possibly also some hydrocarbon and clouds of finely-divided dust, while electric discharges similar to an aurora play an important part in its illumination. It is hoped that yet a method may be devised of studying it independently of eclipses, when more definite knowledge of its structure will speedily be obtained.

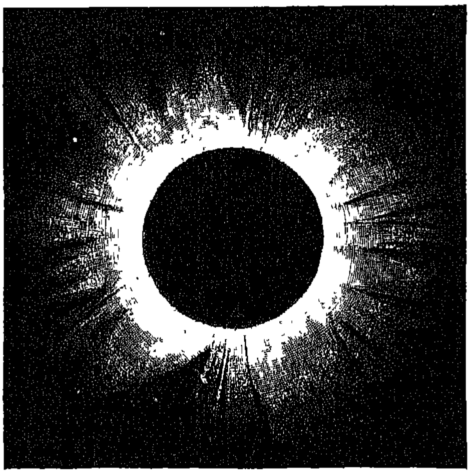

Fig. 3.—Corona during Total Eclipse of the Sun, 12th December 1871. From plate engraved from photographs taken at Baikal, on the Malabar coast of India, by Mr Davis, Lord Crawford's assistant (see *Memoirs of the Astronomical Society*, vol. xli., 1879).

SUN-WORSHIP.—In early philosophy throughout the world the sun and moon are regarded as alive and credited with sex, as brother and sister or husband and wife; but their worship cannot be said to be universal among the lower races, being more especially characteristic of the higher levels of savage religion, of tillers of the soil rather than nomads, of temperate rather than torrid climates. Thus, it was the main worship of the old pastoral Aryans, as may still be seen in Brahman rites, and it appears in the Persian Mithra, the Greek Helios, the Egyptian Ra. It flourished in Tartary, in the fullest development in ancient Peru, and widely among the North American Indians, while in Africa it is hardly found except in Egypt, and in Australia and Polynesia it is seen much more plainly in myth than in religion. And the rites of worship of earthly Fire lead naturally upwards to the religion of heavenly Fire in its great personification, the Sun. But while we give its place to the great nature myth of the Sun slaying the Darkness of Night and Winter, we need not read it into everything in mythology after the fashion of the ingenious vagaries of professed solar mythologists like Max-Muller, Cox, and A. de Gubernatis. The worship of the sun lingered long even under the shadow of Christianity, which was skilful to turn its rites to profit. Thus, these survive disguised in the Easter bonfires, as do its great Festivals in the Yule Log bonfires of Christmas Day—*Dies Natalis Solis Invicti*—the Roman winter solstice-festival, identified as early as the 4th century with the birthday of Jesus, but on no adequate historical evidence, and in its pendant at Midsummer, with its fire-wheels and bonfires. See APOLLO, BELTANE, CHRISTMAS, FIRE-WORSHIP, FOLKLORE, MYTHOLOGY, PARSEES, SOLAR MYTH, and ZOROASTER.

Sunbirds (*Nectariniidæ*), a family of Passerine birds related to the Honey-eaters (q.v.), having tenuirostral beaks and a protrusible and deeply-cleft tongue. In general appearance and habits they resemble the Humming-birds of America, with which, however, they have no real affinity. They are birds of brilliant plumage, glittering with metallic lustre. They are confined to the hotter regions of the Old World, being particularly abundant in Africa and southern Asia and extending to North Australia, but the species commonly have a limited range. Captain Shelley in his monograph on the Sunbirds (Lond. 1876-80) subdivides the family into three sub-families, (1) Neodrepaninæ, (2) Nectariniinæ, (3) Arachnotherinæ. They are all of small size, although none are so small as the smallest humming-birds; they rival humming-birds in brilliancy of plumage, and like them they feed on the juices of flowers, which they suck by their long bill, occasionally hovering in the air before a flower when feeding, but generally hopping about or clinging to the smaller twigs and flowering branches. They have a feeble chirping note. They feed partly on the nectar of flowers, but also on small cicadellæ, flies, and spiders. *Cinnyris* is a synonym of *Nectarinia*.

Sun-bittern (*Eurypyga helias*), so called from the brilliant many-coloured markings on its plumage, a South American bird about the size of a small curlew, long legged and long necked, which usually struts in a solemn balanced manner, but at times goes through a series of poses somewhat like the Argus (q.v.). It is found from Brazil northwest into Central America.

Sunbury, capital of Northumberland county, Pennsylvania, on the Susquehanna River (here, a mile below the junction of its branches, crossed by a bridge), 53 miles by rail N. of Harrisburg. It contains foundries, machine-shops, and planing-mills. Pop. (1890) 5930.

Sun-cracks, superficial markings frequently seen on the surfaces of thin bedded flagstones and argillaceous sandstones. They are believed to have been formed in the same way as the fissures which are produced upon the mud-flats of tidal rivers or estuaries by the drying and shrinking of the deposits during their temporary exposure at low tide. The cracks are of course filled up by new deposits when the mud-flats are again overflowed. Not infrequently the material filling the sun-cracks is of harder consistency than the rock in which they occur. When the bed overlying the cracks is removed a cast of these often projects from its under surface, or frequently the casts remain in the moulds so as to form a series of polygonal ridges ramifying over the whole surface of the exposed stratum.

Sunda Islands, a name that bears in geography two interpretations. (1) It is applied, but not very correctly, to the long chain of islands which stretches from the Malay Peninsula south-east to the north coast of Australia, beginning with Sumatra and ending with Timor. (2) In the more proper sense of the term it means the islands that lie between the east end of Java and the north side of Timor, namely Bali, Lombok, Sumbawa, Flores, Sandalwood Island, and some smaller ones. These have been already treated of in separate articles, with the exception of Lombok. This island, with an area of 2098 sq. m. and a pop. of 405,000, is traversed by two chains of mountains (highest summit, 11,620 feet), some of which show signs of volcanic activity, and yields rice, maize, cotton, tobacco, sugar, indigo, and coffee; three-fourths of the people are aborigines (Sassak); all, except 20,000 immigrant Balinese (Brahmans), profess Islam. The Dutch have exercised suzerainty over the native chiefs since 1840. The principal town on the island is Mataram on the west coast.

Sunda Strait is a passage, from 70 to 90 miles in breadth, lying between Sumatra and Java and connecting the Indian Ocean with the Sunda Sea. Several islands stud its waters, as Krakatoa (q.v.), Princes Island, Steers, and Calmeijer.

Sundarbans, or SUNDERBUNDS, the lower portion of the delta of the Ganges in British India, extending from the mouth of the *Húgli* on the west to the mouth of the Meghna on the east, a distance of 165 miles, and stretching inland for half that distance. The total area is estimated at 7550 sq. m. The region is entirely alluvial, is intersected by a network of anastomosing streams, and contains a vast number of swamps and morasses. Next the sea is a wide belt of dense jungle and underwood, the haunt of the tiger, leopard, rhinoceros, buffalo, wild hog, deer, monkeys, python, cobra, and numerous sea-birds and birds of prey. Behind this belt the land is cultivated, the fields being enclosed with embankments. Rice is the staple crop, though the people also grow pulses, vegetables, jute, and sugar-cane. Besides rice the principal products of the region are timber and fish. There are no villages, the population being thin and scattered. The population are counted in the adjoining districts of Bengal, and there is no separate return for the Sundarbans as a whole. Of course the chief highways are the innumerable watercourses, shown in the map at the article CALCUTTA. See *Petermann's Mitteilungen*, Ergänzungsheft (1891).

Sunday. See SABBATH.

Sunday-schools, as we know them in modern times, sprang from the efforts begun in 1780 by Robert Raikes (q.v.), a printer in Gloucester. Although systematic and wide-spread attention to the religious training of children is of modern date, still some attention was bestowed upon it in early times. The father acted as teacher and priest towards the children in patriarchal times; there was provision for the training of children in the knowledge of the law in the Jewish economy. Ezra read and had the law explained 'before the congregation both of men and women and all that could hear with understanding' (Neh. viii.). There were religious schools in connection with the synagogues in New Testament times. The Mishna says, at five years of age 'let children begin the Scriptures, at ten the Mishna, and at thirteen let them be subjects of the Law.' In the apostolic age teachers were set over the young and ignorant. Mosheim says 'the Christians took all possible care to accustom their children to the study of the Scriptures, and to instruct them in the doctrines of their holy religion.' Clement of Alexandria and Origen did duty as catechists. The classes of Catechumens (q.v.) were intended for the instruction of candidates for church fellowship; instruction was given on Sundays just previous to public worship, and the scholars were mostly adults. At the Reformation Luther (1529), finding the people fearfully ignorant, opened schools for children for catechising. Knox (1560) did the same in Scotland. St Charles Borromeo (q.v.), Archbishop of Milan, founded Sunday-schools in his diocese, which still exist, but these were chiefly secular. Sunday-schools are noticed in an ordinance of Albert and Isabel in 1608 as then existing in the Catholic Netherlands. The magistrates were enjoined to see to their establishment and support in all places where not already set afoot. Both Richard Baxter and the Rev. Joseph Alleine (1634–68) were in the habit of gathering young people together for instruction; and there were many irregular and isolated attempts in the same direction in different parts of Britain. But it was Raikes who founded and consolidated the modern Sunday-school system and gave the subject publicity through his journal and other organs of public opinion. There is no doubt that his philanthropic work in Gloucester gaols had impressed him with the direct connection between ignorance and crime. One day, in 1780, he had gone to hire a gardener in a low suburb of the town near the Severn, where the people were mostly employed in a pin-factory. He was grieved at seeing the groups of wretched ragged children at play in the streets, and on inquiry was informed that on Sunday 'the street was filled with a multitude of wretches, who, having no employment on that day, spent their time in noise and riot, playing at chuck, and cursing and swearing in a manner so horrid as to convey to a serious mind an idea of hell rather than any other place.' To check this deplorable profanation of the Lord's Day he engaged four women, who kept dame-schools, to instruct as many children as he should send them on the Sunday in reading and the church catechism, for which they were to receive one shilling each for their day's service. In this work he was assisted by the Rev. Thomas Stock, of St John's parish. The children gathered into the first Sunday-schools ranged from six to twelve or fourteen years of age. Personal cleanliness was the one requirement. 'All that I require,' said Raikes, 'are clean hands, clean faces, and their hair combed.' Owing to the total ignorance of the scholars the teaching was of an educational nature at first; the little folks learned their letters, and to spell and read. The schools opened at 8 A.M., by 8.30 lessons were begun; afterwards the children went home, or to forenoon service, and in the afternoon to school again at the close of the church service till 5.30 P.M. Boys and girls were separately taught, and once a month they were publicly catechised in church as to their religious knowledge. In a short period a visible improvement was effected in both the manners and morals of the children. One employer of labour said 'the change could not have been more extraordinary had they been transformed from the shape of wolves and tigers to that of men.' More than three years after its foundation the scheme was noticed in Raikes's *Gloucester Journal* (November 3, 1783); but it was a letter by Raikes, quoted in the *Gentleman's Magazine* in 1784, which first drew general attention to the subject. In 1784 the first Sunday-school was established in London by the Rev. Rowland Hill. Numerous schools sprang up in all the principal towns, and a society under high patronage was formed in London in 1785 for the establishment and support of Sunday-schools throughout the kingdom, which in fourteen years spent £4000 in payment of teachers. By 1789 there were already 300,000 scholars throughout the kingdom. Hannah More (q.v.) started a school in 1789, and Sydney Smith one at Netheravon. Adam Smith wrote that 'no plan has promised to effect a change of manners with equal ease and simplicity since the days of the apostles;' and Cowper and John Wesley likewise approved of the system.

One great impediment to the early prosperity of the Sunday-school was the expense of hiring so many teachers. But several young men banded themselves together to teach the children gratuitously; the example spread, and soon the teaching was almost universally gratuitous. One authority says gratis teaching began at Oldham. A higher class of teachers offered their services; the schools ceased to be filled by the very poorest alone; handsome buildings were erected in connection with the different churches and chapels, or by general subscription, and that system was organised which has covered the land with schools. The secular teaching, which in certain instances included writing and arithmetic, was not of a very high order; but it placed the key of knowledge in the hands of multitudes who would otherwise have been unable to read, and the religious instruction with which it was combined moulded the character of some of the best men in England.

Sunday-schools were introduced into Wales in 1789 by the Rev. Thomas Charles of Bala (one of the founders of the Bible Society, q.v.), and were much appreciated even by adults—in one class at Bangor every pupil wore spectacles. The Sunday-school was known in Scotland in 1756, but it was not till 1786, when the Society for Promoting Religious Knowledge was formed, that it was publicly recognised, nor till 1795, when the Gratis Sunday-school Society was originated, that schools became general. At first they met with considerable opposition from both the civil and ecclesiastical authorities. The names of Dr Chalmers, James Gall, and David Stowe deserve mention in connection with the progress of Sunday-schools in Scotland. In Ireland Sunday-schools had been partially anticipated by Dr Kennedy, in County Down, in 1770; but it was not till 1785 that the system pursued by Raikes was adopted. The Sunday-school Society for Ireland was established in 1809. Of the teaching it may be said that good progress has been made since the passing of the Education Act, and it has more of a scriptural nature than formerly.

In the United States, as in Great Britain, there were isolated attempts at Sunday-school teaching before the example of Raikes reduced it to a system. The Methodist Bishop Asbury (q.v.) is said to have planted the first American Sunday-school in Hanover county, Virginia, in 1786. The Methodist Conference in 1790 resolved to establish Sunday-schools for white and black children. A Sunday-school Union was formed at Philadelphia in 1791 which employed paid teachers; the New York Union was formed in 1816; and the American Sunday-school Union in 1824, which sprang from the Sunday and Adult School Union (1817). During the first fifty-nine years of its existence 74,000 Sunday-schools were organised, with 466,000 teachers and over 3,000,000 scholars. In missionary work £565,000 had been spent, and £120,000 in grants of books and papers. The Congregationalists, Methodist Episcopalians, Presbyterians, and Baptists have also organisations, and now the United States stands in the forefront as regards the excellence of buildings and the vigour and earnestness with which the work has been prosecuted. Dr Vincent, one of the founders of Chautauqua (q.v.), which sprang from a Sunday-school Convention, deserves mention for the excellence of his Sunday-school lessons. Along with Mr Jacobs of Chicago he took the initiatory steps which led to the publication of the International Series of Lessons (1873) now used on both sides of the Atlantic. Sunday-schools were introduced into the West Indies in 1810, into France in 1815, and about the same time into Ceylon and at Serampore. The Sunday-school is an invariable adjunct to the work of the missionary. The Roman Catholics have also numerous Sunday-schools.

The establishment of the English Sunday-school Union in 1803 gave a powerful impetus to the extension of Sunday-schools through the agency of ministers and churches, and the improvement of the voluntary teachers engaged in the cause. Missionaries are supported on the Continent and elsewhere. Lectures are delivered, there are travelling agents, and a publication department which issued eighty new books in 1890 and circulated over 10,000,000 of their serial publications. The catalogue of books offered for sale now contains 1500 volumes suitable for libraries. Its affiliated schools in 1890 numbered 6528, teachers 153,851, and scholars 1,501,729. The Church of England Sunday-school Institute (1844) estimates the number of scholars in England and Wales connected with the Church of England as 2,220,000, with 195,500 teachers. The Wesleyan Sunday-school Union dates from 1874, and in less than ten years had 800,000 scholars. A Sunday-school jubilee celebration was held in 1831; the centenary was observed in 1880, and a monument erected bearing the names of Cardinal Borromeo, Thomas Stock, and Robert Raikes.

In 1818 the Sunday scholars in England and Wales numbered 477,225; in 1833, 1,548,890; and in 1851, 2,407,642; Scotland at the same date having 292,549, and Ireland 272,112. The numbers in America were 3,000,000. The report of the International Convention of 1881 for the United States gave 84,730 schools, 932,283 teachers, and 6,820,835 scholars. At the centenary celebration of 1880 the total number of teachers in the world was given as 1,425,233, and of scholars 12,107,312. Mr F. J. Hartley, of the Sunday-school Union, gave the number of Sunday-school teachers and scholars throughout the world in 1890 as follows :

	Teachers.	Scholars.
England and Wales	616,941	5,733,325
Scotland	59,213	651,975
Ireland	28,132	310,009
Total United Kingdom	704,286	6,695,399
United States of America	1,100,104	8,315,431
European Continent	58,308	1,027,177
Australasia	49,283	580,227
Canada and Newfoundland	57,212	490,109
In connection with the several Missionary Societies in India	5,744	110,270
Do. West Indies	9,523	108,233
Do. Africa, China, Japan, Persia, and Central America	12,145	363,259
Total	1,996,605	17,720,135

Sunderland, a seaport, municipal, county, and parliamentary borough and market-town of Durham, situated at the mouth of the Wear, 13 miles NE. of the city of Durham and 12 SE. of Newcastle-upon-Tyne. The township of Sunderland is on the south side of the river, covering an area of 219½ acres, and forms but a small portion of the municipal borough, which comprises also the townships of Bishopwearmouth, Monkwearmouth, and Monkwearmouth Shore. Monkwearmouth appears in history in 674 as the site of a monastery erected by Benedict Biscop (*q.v.*), and Bishopwearmouth in 930 as one of the places conferred by Athelstan on the monks of Lindisfarne then settled at Chester-le-Street. The earliest indubitable reference to Sunderland itself does not occur till 1311. Sunderland is a fine, well-built town, with broad, clean streets and pleasant suburbs. Till the beginning of the 19th century Sunderland was a very inconsiderable place, but since then, owing to the improvement of the harbour and the growth of the Durham coal trade, it has developed with great rapidity. The principal public buildings and institutions are the town-hall, a fine new building in the style of the Italian Renaissance, erected 1887–90; the Free Library, Museum, Art Gallery, and Winter Garden (1877–79); Sunderland Literary Society and Subscription Library (1878); the Theatre Royal (1853); the Avenue Theatre; the Victoria Hall, the scene of the terrible disaster of June 16, 1883, in which 182 children lost their lives (1872); the Assembly Hall; the Workmen's Hall (1868); the Liberal Club (1839); the County Constitutional Club (1890); the Infirmary (built 1865; enlarged 1879–87); the Orphan Asylum (1860). There are twenty churches in the borough (seventeen belonging to the Church of England and three to the Roman Catholic Church). St Peter's, Monkwearmouth, retains in a part of the tower and west wall of the nave a remnant of the 7th-century building. There are between fifty and sixty chapels and meeting-houses in the borough belonging to the various dissenting bodies. Sunderland possesses in the People's or Mowbray Park an excellent recreation-ground. The portion south of the railway was purchased in 1854, and contains monuments of Havelock and Jack Crawford. The portion north of the railway, called the New or Extension Park, was purchased in 1866. The village of Roker, a popular watering-place close to Monkwearmouth, also has a park of 17 acres, opened in 1880. Two single-arch iron bridges cross the Wear at a distance of 20 yards from each other. The older bridge, having the large span of 236 feet, was built 1793–96. It was reconstructed and widened under the direction of Robert Stephenson in 1858–59. The railway bridge was opened for traffic in 1879. The harbour is formed by two piers, the one on the north being 617 yards long, that on the south 650 feet. A new pier, starting from the south end of the terrace promenade at Roker, is over 2000 feet long. Two other piers protect the entrance to the south docks. There are four docks at Sunderland capable of accommodating the largest vessels—the North Dock (6 acres), the Hudson Dock, North (18 acres), the Hudson Dock, South (14 acres), the Hendon Dock (11 acres). Over 208.000 tons of shipping are registered at the port of Sunderland, and in 1890, 6052 vessels of 2,342,161 tons cleared from it. The annual shipments of coal and coke for the last few years reached upwards of 4,000,000 tons. From the commissioners' staiths 15,000 tons can be shipped in a day. Other exports are bottles and glass, earthenware, lime, iron, chemicals, patent fuel, and cement. The principal imports are timber, props, iron ores, chalk. loam, grain, flour, esparto grass, hay, straw, and tar. Sunderland is famous for its iron shipbuilding-yards, of which there are as many as thirteen on the river. During 1890 eighty-six vessels, registering 125,612 tons, were launched on the Wear. In 1889 the tonnage launched was 217,366. There are also in the town extensive ironworks, forges, anchor and chain works, glass and bottle works, chemical works, roperies, paper-mills, breweries, and lime-kilns. In Monkwearmouth is the Pemberton coal-pit, 381 fathoms deep, several of the workings extending under the sea. Sunderland returns two members to parliament. Pop. of parliamentary borough (1851) 67,394; (1881) 124,760; (1891) 142,097, of whom 130,921 were in the municipal and county borough. Havelock was born at Ford Hall, Bishopwearmouth (1795); Jack Crawford, the hero of Camperdown (1775–1831), at Sunderland; and other natives were Clarkson Stanfield, R.A., Tom Taylor, and Swan the electrician.

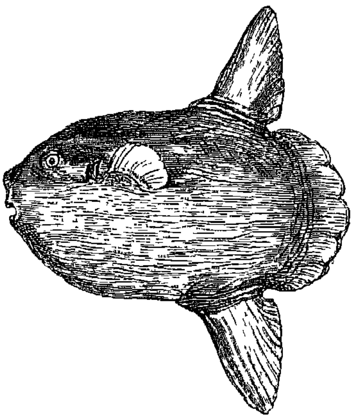
Sunderland, ROBERT SPENCER, EARL OF, was born in 1640, and in September 1643 succeeded his father, who fell at the first battle of Newbury, having three months before been created first earl. After serving as ambassador to several courts, in 1679 he became Secretary of State, and at first united with Essex and Halifax in opposing Shaftesbury, who wished to set Monmouth on the throne, and favoured the exclusion of the Duke of York. He encouraged Charles II. to persevere in the degrading French alliance, and, with the Duchess of Portsmouth, to whom he attached himself, negotiated a treaty by which, in consideration of an annual French pension, Charles was to assemble no parliament for three years. Before the year was out a new triumvirate, consisting of himself, Hyde, and Godolphin, succeeded to the confidence of Charles. The treaty with France was broken off, and Sunderland, who was now afraid of the Whigs, engaged the king in a more popular alliance with Spain. After the dissolution of the last of the exclusion parliaments he lost his office; but the duchess remained faithful to him in disgrace, and in 1682 he was, 'upon great submission made to the Duke [of York], again restored to be Secretary.' He remained in office until the accession of James II., when his influence in the ministry became greater than ever. Although there is reason to believe he gave some encouragement to Monmouth in his rebellion, he managed, with consummate art, to win James's entire confidence, and in 1685 became prime-minister. He alone was entrusted with a knowledge of the king's intention to establish Catholicism as the national church; and in 1687 he privately conformed thereto, and afterwards openly professed his conversion. His influence was so great that James would grant no favour until he had asked the question: 'Have they spoken to Sunderland?' and when told that this nobleman got all the money of the court, he would reply: 'He deserves it.' Yet we find him about this time in correspondence with William of Orange. With profligate but masterly dexterity he contrived to deceive both James and Barillon, and to keep them in ignorance of the events that were passing in Holland. When William arrived in England Sunderland went to Amsterdam, whence he wrote to the new monarch, claiming his favour and protection on the ground that he had all along been in his interest. In 1691 he was allowed to return to England, and to kiss the king's hand; in 1695 William spent a week at his house at Althorp. He had changed, it was said, his religion, in the late reign, in order the more effectually to ruin King James; and it was generally believed that he had rendered King William, when Prince of Orange, some signal services, which no one else could have done. This belief gained credit from the favour now shown him. He was made Lord Chamberlain, and as such took his seat at the head of the council table. After directing affairs as the acknowledged head of the government, he resigned office in 1697, and retired to Althorp, where he died, 28th September 1702. By his wife, Anne, daughter of the second Earl of Bristol, he left CHARLES SPENCER, third earl, who was born in 1675, and whom Evelyn describes as a youth of extraordinary hopes, very learned for his age, and ingenious. From 1706 to 1710 he was Secretary of State in the reign of Queen Anne, and under George I. he rose to be all-powerful; but in 1721, being accused of receiving £50,000 worth of the fictitious stock distributed by the directors of the South Sea Scheme (q.v.), in order to bribe the government, he was acquitted only by an inconsiderable majority and that from party considerations, and the indignation of the public made him resign his office. He died on 19th April 1722, not without suspicion of having intrigued, after his fall, for the restoration of the Tories, if not for the return of the Pretender. Sunderland was a type of the political morality, or rather immorality, of a disgraceful age, when the greatest statesmen made no scruple of sacrificing either their own party or the interests and dignity of the nation to personal ambition. His title descended to Charles, his second son, who succeeding in 1733 to the honours of his maternal grandfather, John Churchill, the earldom of Sunderland became absorbed in the dukedom of Marlborough. The third son, John, was father of the first Earl Spencer (q.v.).

Sundew. See INSECTIVOROUS PLANTS.

Sun-dial. See DIAL.

Sundsvall, a seaport of Sweden, on a bay of the Gulf of Bothnia, 80 miles N. by W. of Stockholm, and 290 miles by rail E. by S. from Trondhjem in Norway, has ironworks and sawmills, and a large trade in iron and timber. Pop. 10,726. The town was almost entirely destroyed by fire in 1888.

Sunfish (*Orthagoriscus*), a genus of pelagic fishes of the family Diodontidæ (see GLOBE-FISH), having the body compressed, and not capable of inflation, as in the other Diodontidæ; abruptly terminating in a very short tail; the dorsal and anal fins long and pointed, united to the short tail-fin; the jaws undivided in the middle, and comparatively feeble, and furnished with a cutting edge of bone instead of teeth. The total number of vertebræ is seventeen, and the spinal cord is merely a short appendage of the brain. The species are found in every part of the oceans within the tropical and temperate zones. The young undergo remarkable changes. The food consists of small pelagic crustacea. The Short or Rough Sunfish (*O. mola*), found frequently on the south coasts of England and Ireland, when young is almost perfectly round, but becomes rather more elongated when full grown. The name Sunfish is variously regarded as derived from the form of the fish and from its habit of floating at the surface of the water, in fine weather, as if to enjoy the sunshine. It attains a large size, being sometimes 7 or 8 feet long, and is captured by sailors. Its skin is rough and minutely granular. Its flesh is white and well flavoured, somewhat resembling that of the skate. The liver yields a large quantity of oil, which is in repute among sailors as an external application for the cure of sprains, rheumatism, &c. The Oblong Sunfish (*O. truncatus*), of which specimens have also been taken on the British coasts, but more rarely, is of a longer form. It also attains a large size. It has a smooth tesselated skin, and is one of the rarest fishes in collections.



Short Sunfish (*Orthagoriscus mola*).

Sunflower (*Helianthus*), a genus of plants of the natural order Compositæ, sub-order of Corymbiferæ, having large flowers; the florets of the ray strap-shaped, without stamens or pistils, yellow or orange; the florets of the disc tubular, perfect, yellow or purplish brown; the flowers solitary or in corymbs, with an involucre of numerous leaves; the fruit compressed, with a pappus of two or more deciduous scales. The species are numerous, all natives of America; large herbaceous plants, with opposite or sometimes alternate undivided leaves. The Annual Sunflower (*H. annuus*), common in flower-gardens, is a native of tropical America, where it sometimes attains a height of 20 feet. The stem is thick and rough; the flowers solitary, and from 1 foot to 2 feet in diameter, nodding; the leaves heart-shaped-ovate. This plant is now cultivated in almost all parts of the world, and in the south of Europe is sometimes a field-crop, the seeds being valued as food for cattle and poultry, and on account of the oil which they yield, which is little inferior to olive-oil. An acre of good land produces about fifty bushels of seed, each bushel yielding a gallon of oil. The seeds are also used like almonds for

Sunflower
(*Helianthus multiflorus*).

making demulcent and soothing emulsions; and in some parts of Europe a bouilli is made of them which is used as food for infants. Russians eat them like nuts, and American Indians make bread of them. The flowers abound in honey, and are much frequented by bees. The leaves are good fodder for cattle. The stems are used for fuel, and yield much potash. A profusely flowering garden variety, *H. multiflorus*, is referred to the same species. The fallacy that the flowers of the sunflower turn with the sun is mentioned by Gerarde (1597), who adds, however, 'the which I could never observe, although I have endevored to finde out the truthe of it.'—The Jerusalem Artichoke (q.v.) belongs to this genus.

Sungei Ujong, a native state of the Malay Peninsula under British protection, lies on the west side, between the British colony of Malacca and the native state of Selangor. Area, 660 sq. m.; pop. (1889) 20,000, mostly Chinese. The productions are the same as those of the neighbouring Straits Settlements (q.v.).

Sunium. See COLONNA.

Sunn. See CROTALARIA, FIBROUS SUBSTANCES.

Sunnites, the name commonly given to orthodox Muslims, because in their rule of faith and manners the Sunna (pron. *Soonna*), or traditionary teaching of the Prophet, is added to the Koran. According to Islam the human mind is incapable of attaining light in law or religion but through the Prophet, and all expressions of God's will are equally important. Reason and conscience are here of no value; memory is all. Hell-fire is the award due alike to him that prays without being properly washed and to him that denies the word of the Prophet. Accordingly during the Prophet's life his counsel was eagerly and continually sought; and after his death his example and sayings were collected as of infinite value. After the death of the four rightly guided califs, Abu Bekr, Omar, Othman, and Ali, intimate friends of the Prophet, fearful uncertainty arose and gradually occasioned the four schools of the four orthodox Imâms. The first of these was Abu Hanîfa, born in Basra of a noble Persian family. He taught in Kufa on the Euphrates. He logically deduced from the Koran all religion and law; for the Koran says (Sura 16 : 91) 'to thee we have sent down the book which clears up everything.' Consequently, when the Koran says (S. 2 : 20) 'for you have I created the whole earth,' it follows that to Muslims belongs all the property of unbelievers. Hence the propriety of piracy and aggressive war against them. In his school arose the famous legists of Irâk, and his system, the most widely spread of the four, is now professed by the Turkish empire. He would never hold any office under government, fearing the doom due according to prophetic tradition to every giver of a wrong decision, namely, to be plunged into hell from a height of forty days' journey. He died in 767 in prison, where the calif had confined him for refusing to be Cadi over the new capital Bagdad.

In 795 died Mâlik ibn Anas in his eighty-fourth year at Medina, where he was born and had lived all his days. There, surrounded by traditions of the Prophet, he had taught after the custom of Medina. This had been impossible to Abu Hanîfa, residing amid a partly foreign people and a very complex civilisation. Mâlik gathered from the Koran and from local traditions of Mohammed his *Muwâttaa*, or Beaten Path, a complete body of law and religion. He never announced any such tradition without a previous ablution. On his death-bed he regretted with tears that he had ever used his own judgment in pronouncing an opinion on a point of law, and wished that he had been flogged and reflogged every time. His system was established in North Africa by African students, who found Medina the most convenient school, and in Spain by his Berber pupil Yahya 'bn Yahya. The third orthodox imâm was Ash-Shâfii of the Koraish tribe, and descended from the Prophet's grandfather, Abdul-Müttalib. He was born, it is said, on the day of Abu Hanîfa's death. He taught in Cairo, and there he died in 820. He was an eclectic, but leaned more to the traditionary precedents of his teacher Mâlik than to the deductive method of Abu Hanîfa. His system prevailed in Egypt, and was not uncommon eastward. It still flourishes in the Asiatic islands.

The use of reason and Greek philosophy had by this time wrought such laxity in faith and in public and private conduct that rigid puritanism was a natural concomitant. Its exponent was Ibn Hanbal, the fourth orthodox imâm, who died in 855 in his native city Bagdad, beyond which his system never had much power. He was a pupil of Ash-Shâfii, whose lectures, however, he would never allow his own pupils to attend. Tradition and Sunna had now immensely increased, and by these alone the Hanbalites were guided. They are now almost extinct, but were strenuous in their early days, when they would break into festive meetings in Bagdad, beat the singers, break the musical instruments, and pour the wine into the streets. The bulk of tradition had now made editing indispensable, and those huge masses of it began to appear under which the Muslim mind has been crushed to death. As Ibn Hanbal said, 'the punishment of the learned man in this world is blindness of heart.' Abu Hanîfa had used only 18 traditions, Mâlik 300, Ibn Hanbal used 30,000. These were mainly collected by his friends and pupils. One of these, the excellent Abu Daûd Suleimân, travelling in many Muslim lands, collected half a million, which he sifted down to 4800. Another, Yahya 'bn Main, spent a large fortune and wore out his last pair of shoes in collecting 600,000. Helpers copied as many more for him. 'I copied quantities of traditions to the dictation of liars,' he said, 'and heated my oven with them, whereby my bread was well baked.' But of the six accepted collections the standard one was made by Al Bukhâri, a friend and pupil of Ibn Main. He taught in Bagdad, and like the best Muslim theologians was a Persian. He died in 870. Of the 600,000 traditions heard by him he admitted only 7275, whereof the half are probably genuine. Till he had washed and performed two rekas of prayer he never inserted any tradition. An edition by Krehl appeared at Leyden in 1862-72, in 3 vols. The collection by his Muslim pupil is better arranged, and is more used. The sources of tradition were Âyesha, the first four califs, and the six companions of the Prophet, of whom Abu Horaira, a manifest liar, was more prolific than any other. Through one of these channels to Mohammed the *isnâd* or pedigree of every tradition had to be traceable. Worth or internal evidence counted for nothing. The work of collecting was begun too late. The real origin of most traditions was the requirements of interested parties, conscious mendacity, or gossip, specially in the standing camps of Arabs required in every conquered land. The matter is called Hadîth, events, tradition, and is much more entertaining than the Koran. Besides the legal and religious utterances of Mohammed, which are generally in one or two sentences, it embodies endless nonsense about his life and miracles, although Mohammed disowned all miracles but his own inspiration, about spirits, the beginning of the world and its end. Whatever in the Hadith can be imitated or obeyed is Sunna, method; compulsory for guidance if connected with religion, but redundant or collateral, though praiseworthy, if giving mere details of such things as the Prophet's mode of standing and sitting. Its object is to make needless all appeals to reason and conscience. In legislation it is much less used than formerly; but, like the Koran, it is infallible and unalterable, and its only independent expounders are the four orthodox imâms. Legislation merely means a declaration by the Sheikh-ul-Islâm and his council of ulemâ or doctors that this or that agrees with the Koran or tradition. Reformation of law or religion from within is impossible.

Sunstroke (otherwise called Heatstroke, Heat Apoplexy, Heat Asphyxia, Coup de Soleil, Erythismus tropicus, and Insolatio) is a very fatal affection of the nervous system, which seldom occurs in Great Britain, except in extremely hot summers, but is very common in India and other tropical countries. The symptoms of the disease are liable to be greatly modified in different cases. Two contrasted forms are recognised. In the *cardiac* the heart is chiefly affected, and the symptoms are weakness, faintness, dimness of sight, giddiness, &c. Death may take place either suddenly or more gradually from failure of the circulation. If recovery occur it is complete. This form is said to occur only from direct exposure to the sun's rays. In the *cerebro-spinal* form, the commoner of the two, the symptoms usually come on more gradually; nausea and giddiness may be present at first; but the most striking feature of the disease is either wild delirium or coma, with a pungently hot skin and extremely high temperature—106° F. or upwards. Even those who recover from this form of the disease are apt to suffer for a long period, or it may be permanently, from severe headache, epilepsy, enfeebled mental power, or other nervous disorders. Intermediate varieties are also met with, forming links between these two extremes. The mortality from sunstroke is about 50 per cent. of those affected. In the cases that terminate favourably a gradual remission of the symptoms takes place; and when the skin becomes cool and moist, and sleep has been procured (phenomena which usually occur within thirty-six hours of the attack), the patient may be regarded as out of danger.

The predisposing causes of sunstroke are (1) an unusually elevated degree of temperature; (2) heavy or unduly tight clothing, particularly if it interfere with the free expansion of the chest; (3) a contaminated atmosphere from overcrowding; (4) all debilitating causes, such as prolonged marches, previous disease, intemperate habits, &c. Death sometimes occurs so suddenly that there is little opportunity for treatment, but the general indications in these cases are the cold douche, from a height of three or four feet, keeping the surface wet and exposed to a current of air, the exclusion of light as far as possible, and the free employment of stimulants. In less rapidly fatal cases the outer clothing should be removed, and the douche applied, as before, over the head and along the spine. Relaxation of the pupil is the first favourable sign. If the pulse flags the douche must be replaced by the mere application of cold to the head, and it may be necessary to apply hot bottles, &c. to the extremities. The hair must be cut short, and the nape of the neck blistered as speedily as possible. If insensibility recurs after an interval of ten or twelve hours, a blister should be applied to the crown of the head. The extremities and chest should be stimulated with mustard poultices. Immediately after the employment of the douche a strong purgative injection should be thrown up the lower bowel. Under no circumstances should there be any abstraction of blood. If injurious effects persist long after partial recovery, the patient should be removed to a cooler climate. The preventive measures are of more importance than the treatment. There has occasionally been an extraordinary mortality from sunstroke in the United States in very hot summers.

Sun-worship. See SUN.

Suonada, or the Inland Sea of Japan, separates the islands of Kyushu and Shikoku from the main island, Honshu. It is about 250 miles in length from the strait of Shimonoseki (q.v.) to Osaka, greatest breadth about 50 miles, and is studded with innumerable islets and rocks. The scenery is most beautiful, but the navigation is difficult.

Superannuation. See CIVIL SERVICE.

Supererogation, WORKS OF (Lat. *opera supererogatoria*), a class of works which, in the Roman Catholic system, are described as not absolutely required of each individual as conditions to his eternal salvation. The doctrine is based on the distinction between *præcepta* and *consilia evangelica*, the former including the common duties of all, the latter (called also 'Counsels of Perfection') establishing a merit. Roman Catholics found this definition on the distinction between what they believe to be commanded and what they hold to be only counselled, for an example of which they appeal to the words of our Lord to the young man in Matthew, xix. 21, which distinguish one class of works which are necessary in order to 'enter into life,' and a further class which must only be done if we 'would be perfect.' Roman Catholics do not profess to recognise in works of supererogation any distinctive essential quality by which they differ, whether in their physical or their moral entity, from other works, and in virtue of which, by their own nature, the individual may found upon them a personal claim to reward. For works of supererogation, as for all supernaturally good works, they hold that the assistance of God's grace is indispensably necessary; and they do not ascribe to them any merit, except that which arises from God's own free and gratuitous promise. In one word, the only distinctive characteristic of a work of supererogation lies in its not being supposed to be prescribed or commanded as absolutely necessary for the salvation of the individual, and its being done for the sake of greater perfection; and the doctrine which teaches the possibility of such works is, according to Catholics, a necessary consequence of the unequal fervour and unequal degrees of holiness which exist even in the class of the virtuous servants of God. The main difficulty comes in at the next step—the claim that a further consequence of this doctrine is that God may accept the superabundant works of one in atonement for the defective service of another. Hence in the theory of indulgences, along with what they regard as the infinite and inexhaustible treasure of the merits of our Lord, Roman Catholics also regard, although in a degree infinitely inferior, the superabundant merits of the saints as forming part of that 'treasure of the church' which is applied in the form of indulgences. See INDULGENCE.

Superfœtation, or the circumstance of two distinct conceptions occurring in the same woman at a considerable interval, so that two fœtuses of different ages—the offspring possibly of different fathers—may co-exist in the uterus, is a subject of great interest both in a scientific and in a medico-legal point of view. Two centuries ago there was a universal belief in not only the possibility but the comparative frequency of this occurrence. Early in the 19th century it was as universally disbelieved; and now again (owing to the investigations of various inquirers) we are returning to the belief of our ancestors. The cases described as instances of superfœtation may be arranged in three classes; but it is only to the cases of the third class that the term superfœtation is truly applicable. The *first class* includes the numerous undisputed cases in which two mature children, bearing evidence, from their different colours, that they are the offspring of different parents, are born at the same time. (In the slave states of America it was by no means uncommon for a black woman to bear at the same time a black and a mulatto child—the former being the offspring of her black husband, and the latter of her white lover; and the converse has occasionally occurred—a white woman at the same time bearing a white and a mulatto child.) There is no difficulty in accounting for these cases, which may be examples of nearly contemporaneous conception rather than true superfœtation. The *second class* includes those cases in which a twin has aborted, leaving its fellow undisturbed in the uterus, to be matured and born in due time, or in which twins have been produced at the same time, one of which was fully formed, while the other was small and apparently premature, from being 'blighted' or arrested in its development at an early period, or in which the birth of two children, both mature or nearly so, is separated by a short interval. Cases of these kinds are by no means rare; but there is no reason for believing that the infants were conceived at different periods.

The *third class* only presents serious difficulty. 'In a case of genuine superfœtation,' says Dr Bonnar of Cupar, 'a woman must bear two (or more) *mature* children, with an interval of weeks or months between the birth of each; or, if she part with the whole contents of the uterus at the first delivery, the difference of the ages of the fœtuses, or the mature child and the fœtus, as the case may be, must be unmistakable, and there must be the absence of all marks of blight of the latter, so as to leave no doubt that, had it remained in utero, it would have gone on to perfect maturity.' Several apparently well authenticated cases are on record where a second living child has been born three, four, or five months after the first; and these seem inexplicable on any hypothesis except that a second conception has taken place during the progress of the first pregnancy. Theoretical objections to the possibility of such an occurrence cannot outweigh the recorded facts, and by some of the highest authorities are not considered valid for the early months of pregnancy. Cases, moreover, of double uterus occasionally occur; and in the absence of clear evidence to the contrary in any particular case it is possible that the second conception may have taken place in the unoccupied division of such an organ. See Taylor's *Medical Jurisprudence* for further details.

Superior. See CASUALTIES, FEU.

Superior, capital of Douglas county, Wisconsin, at the west end of Lake Superior, and at the mouth of the Nemadji River, 8 miles by rail SE. of Duluth. It has a good harbour and steam sawmills, and has grown up since 1880. Pop. (1890) 11,983.

Superior, LAKE, the largest body of fresh water on the globe, is the highest and most western of the great lakes lying between Canada and the United States. It is bounded on the N. and E. by Ontario, on the S. by Michigan and Wisconsin, and on the NW. by Minnesota. Greatest length, 412 miles; greatest breadth, 167 miles; area, 31,200 sq. m.—nearly that of Ireland. The surface of the lake is $601\frac{8}{10}$ feet above the level of the sea, and its mean depth about 475 feet; its maximum depth is 1008 feet, or 406 feet below the level of the sea. Its surface has an elevation of $20\frac{1}{3}$ feet above that of Lakes Huron and Michigan; this difference occurs in the rapids of St Mary's River, the only outlet (see SAULT STE MARIE), where the average discharge is 86,000 cubic feet per second. Lake Superior, being situated very near the water-shed between Hudson Bay and the Mississippi, receives no rivers of importance, although hundreds of small rivers pour themselves into it, the largest the St Louis and the Nipigon. Its aggregate drainage area (including its own area) is 82,800 sq. m. (Compare the articles on the four other lakes of the system, and those on Victoria Nyanza, Baikal, &c.) Near Dog Lake (318 miles by rail E. of Port Arthur) a short portage connects streams flowing to Lake Superior with others flowing north to Hudson Bay, and by this route furs are brought from the far north.

The northern coast is bold and rocky, and fringed with numerous islands of basalt and granite, some rising sharply from deep water to 1300 feet above the lake. The largest island is Isle Royale, which is 44 miles long. The southern shore is generally lower and more sandy, with occasional ridges of limestone. Keweenaw Point (*q.v.*) projects far into the lake. At Grand Isle Bay, about 100 miles W. of Sault Ste Marie, are the Pictured Rocks, cliffs of sandstone from 50 to 200 feet high, in many places presenting fantastic forms, and marked by numerous vertical bands and blotches of red and yellow. The boundary line between Canada and the United States is drawn through the centre of the lake from its outlet to the mouth of Pigeon River, but is diverted so as to include in the United States Isle Royale.

The water of Lake Superior is singularly pure and transparent. It never freezes over, but the shore ice prevents navigation in winter. The lake also is subject to very violent storms; waves have been observed, during protracted autumn gales, 15 to 18 feet high. It has the small tides common to the great lakes (see MICHIGAN), and also the *seiches* seen in Swiss lakes—a regular series of small waves, or pulsations, at intervals of about ten minutes.

The rocks around the lake are very ancient, belonging principally to the Laurentian and Huronian systems of the Azoic series, overlaid in some places, especially on the south side, with patches of the Lower Silurian (soft sandstones). There is everywhere much evidence of glacial action. On the north side, both on the islands and shores, copper and silver are worked, especially at Thunder Bay; while the copper and red hæmatite iron ores of the south side are celebrated for their extent and richness (see COPPER, p. 464). The principal towns on the Canadian side are Sault Ste Marie and Port Arthur, and on the American side Duluth, Superior, and Marquette, all of which are discussed separately. The Canadian Pacific Railway passes along the northern shore. See Crosman's *Chart of the Great Lakes* (Milwaukee, 1888).

Superphosphates. See PHOSPHORUS.

Supervision, BOARD OF. See POOR-LAWS, Vol. VIII. p. 315.

Supple Jack, a name given in the southern United States to the *Berchemia volubilis*, a twining shrub of the natural order Rhamnaceæ, which is found as far north as Virginia. It has oval leaves, small flowers, and violet-coloured berries. Some of the tropical American Paullinias are also called Supple Jack. The same name is also given in the West Indies and tropical America to *Serjania* (or *Seriana*) *triternata*, a shrub of the natural order Sapindaceæ (q.v.), with a long, flexile, woody stem, which climbs to the tops of the highest trees, and is used for walking-sticks.

Supply. See DEMAND AND SUPPLY.

Supply, COMMISSIONERS OF, so called because they were originally appointed for the purpose of levying and collecting the land tax or cess offered as 'supply' to the sovereign, were long the chief county authority in Scotland for administrative and rating purposes. They were first appointed by the Act of Convention of 1667, and in order to qualify them to act they required formerly to be possessed of £100 Scots of yearly valued rent in property, superiority, or liferent. Until 1854 they were individually named in acts of supply; but since the passing of the Valuation Act in that year they have consisted of all owners of lands and heritages (other than houses) of the annual value of £100, of owners of houses of the value of £200 a year, of the eldest sons of owners of lands of £400 annual value, and, in the absence of their constituents, of the factors of owners of £800 a year, together with the sheriff and sheriff-substitute and certain representatives of the burghs within the county. It was by them that the general business of the county used to be conducted; they executed the statutes regulating its administration and finance; under the County General Assessment Act of 1868 they raised by rate the money necessary to meet the general expenditure of the county; they prepared annually a valuation roll of all lands and heritages within the county; they appointed the county officials; and in each county, with the exception of Orkney and Shetland, they maintained a force of police. By the Local Government (Scotland) Act, 1889, all these powers and duties were transferred to and vested in the County Council. Under the Act of 1889 the Commissioners of Supply still meet annually in May on the same day as the County Council. They transact no business, however, other than electing a convener and concurring with the County Council in the appointment of a standing joint committee which superintends the police and the capital expenditure of the county. For a parliamentary Committee of Supply, see PARLIAMENT, Vol. VII. p. 774.

Supporters. See HERALDRY, Vol. V. p. 667.

Suppuration is a morbid process which gives rise to the formation of Pus (q.v.), which, as is well known, is one of the commonest products of inflammation. The fluid portion of pus is agreed by all to be derived mainly from the liquor sanguinis; but with regard to the origin of the pus-corpuscles there has been a singular fluctuation of opinion. Before 1850 it was generally held that they developed in the fluid exudation of an inflammation by aggregation or growth of granules contained in it. This doctrine was replaced by that of Virchow (1858), who believed that they resulted from rapid multiplication of the cells of the irritated tissue. In 1867 Cohnheim, repeating accurate but neglected observations made in England more than twenty years before, showed that during Inflammation (q.v.) white blood-corpuscles escape from the capillaries, and make their way through the tissues; and he maintained that these, and not fixed tissue-cells, give origin to pus-corpuscles. At present Cohnheim's view is generally regarded as the true explanation in the majority of instances; but it is maintained by some pathologists that at least in some cases many of the corpuscles arise from multiplication and alteration of the cells of the inflamed tissue, an opinion which has not yet been altogether disproved.

With regard to the causes which lead to suppuration there has been almost as great a change of current opinion during the same period. It used to be regarded as the natural result of any kind of severe irritation, and a necessary incident in the healing of the great majority of wounds. But when Lister demonstrated the possibility of preventing it in many cases by Antiseptic (q.v.) methods, and when micrococci were found in the pus of many abscesses, even where there had been no visible breach of surface, it became clear that microscopic organisms play an important part in the process. The experiments of some observers indeed led them to conclude that though some of the results of inflammation may be manifested, suppuration cannot take place without their presence and activity. It has been shown, however, (1) that dead micro-organisms can excite suppuration; (2) that a fluid in which they have grown, even when completely freed from solid particles, can do so—i.e. that their influence depends at least in part not on the organisms themselves, but on chemical products of their growth; (3) that certain chemical irritants (e.g. mercury, turpentine, croton-oil) experimentally introduced into the tissues of animals with the most complete antiseptic precautions do lead to suppuration. Such conditions, however, can hardly occur except as the result of a carefully planned experiment; and in cases coming under the care of the surgeon it may be assumed that where suppuration is present it is due to micro-organisms.

Suppuration must thus be regarded as one phase of that effort of the organism to resist the causes of disease which takes so prominent a place in pathology at the present day. But though essentially a defensive process, it very frequently becomes harmful, and leads to serious results. If suppuration takes place beneath a surface which does not participate in the morbid change, or which is capable of resisting it for a time, an *abscess* is formed; when pus-cells are poured forth from an exposed surface we have an *ulcer*.

For some of the controverted points discussed above, see Leber, *On the Origin of Inflammation*, &c. (Leip. 1891), and Metschnikoff, *On the Comparative Pathology of Inflammation* (Paris, 1892).

Supralapsarian. See PREDESTINATION.

Supra-renal Capsules, two small, flattened, glandular bodies of a yellowish colour, situated, as their name implies, immediately in front of the upper end of each Kidney (q.v.). In weight they vary from one to two drachms. They belong to the class of ductless glands, and on making a perpendicular section each gland is seen (like the kidney) to consist of cortical and medullary substance, surrounded by a fibrous investment which is intimately connected with the subjacent structure, and is continuous with the fibrous stroma which pervades the organ. In the cortical portion the cells are arranged in rows or columns, and are polyhedral in shape, while in the medullary portion the stroma forms a network, in the meshes of which groups of cells of more irregular outline are found. The blood-vessels and nerves of the glands are exceedingly numerous. Their function is extremely obscure, and with regard to it nothing is positively known. In 1855, however, the late Dr Addison showed that a rare form of disease, characterised by progressive debility and emaciation, with increased pigmentation of the skin (known as *Addison's Disease*, or *Bronzed Skin*), is associated with disease of these organs. It has since been proved that only one particular form of degeneration leads to this result; cancer, sarcoma, &c. have no similar consequence.

Supremacy, ROYAL. The term supremacy is, in politics, chiefly used with regard to authority in matters ecclesiastical. From the time of Pope Gelasius (494 A.D.) to the Reformation the pope exercised a very extensive authority, judicial, legislative, and executive, over all the churches of western Europe, somewhat undefined in its limits, varying in different countries and at different periods; and this continues to be more or less recognised in all countries whose inhabitants are in communion with the Church of Rome. The Statutes of Provisors (q.v.) and Præmunire (q.v.) asserted in some measure the authority of the sovereign; but at the English Reformation the papal supremacy was abolished, and 26 Henry VIII. chap. 1 declared the king and his successors to be the 'only supreme head on earth of the Church of England.' A document was at the same time drawn up by the government, in which it was explained that the recognition of this headship of the church implies only that the king should have such power as of right appertaineth to a king by the law of God, and that he should not take any spiritual power from spiritual ministers, or pretend to 'take any power from the successors of the apostles that was given them by God.' In 1535, the year in which this act was passed, Bishop Fisher of Rochester, Sir Thomas More, and others were beheaded for denying the king's supremacy. On Elizabeth's accession it was thought prudent, while again claiming the supremacy in all causes, as well ecclesiastical as civil, to keep that designation in the background. By successive statutes the oath of supremacy was appointed to be taken by the holders of public offices along with the oath of allegiance and of abjuration; these three oaths were consolidated into one in 1858; and now the oath of supremacy is not explicitly imposed on members of parliament. See Oath, England (Church of), Henry VIII.

Supreme Court of Judicature, in England, comprises the Court of Appeal (q.v.) and the High Court of Justice, with its four divisions—Chancery, Common Law, Bankruptcy and Probate, Divorce and Admiralty, all separately dealt with. In Scotland the term refers to the Court of Session (q.v.) and the Justiciary Court (q.v.).

Surabaya, a seaport on the north coast of Java, and on the strait of Madura, over against the island of Madura. Here the Dutch have a marine arsenal, a cannon-foundry, and a mint, and there are machine, sugar, and furniture factories, shipbuilding-yards, and foundries. Sugar, coffee, hides, and tobacco are the chief articles exported; rice and cotton are also grown in the province (area, 2327 sq. m.; pop. 1,856,635), of which Surabaya is the capital. Pop. 127,403, of whom more than 6000 are Europeans and nearly 7500 Chinese.

Suraja Dowlah. See Black Hole, Clive.

Surakarta, a town in the centre of Java, but connected by rail with Samarang on the north and Surabaya on the east. It is the residence of the native sultan of Surakarta, who, however, is a dependent of the Dutch government and is advised by a resident. The town (pop. 124,000) is the capital of his kingdom, a mountainous but in part very fertile region, with an area of 2191 sq. m. and a pop. of 1,053,985.

Surat, a city of British India, on the south bank of the river Tapti (crossed by a five-girder bridge), 14 miles from its mouth, and 160 by rail N. of Bombay. It stretches in a semicircle for more than a mile along the river, the quondam citadel (1540; government offices since 1862) forming the central feature in the line. The houses are closely packed, but the streets are clean and well paved; beyond them lie the suburbs, widespread in the midst of gardens. The chief ornaments of Surat are four handsome Mohammedan mosques, two Parsee fire-temples, three Hindu temples, the old English and Dutch factories, and a clock-tower (80 feet high). The existing city was founded early in the 16th century, and very soon after (in 1512) was burned by the Portuguese, who burned it again in 1530 and 1531. A stronger fort was erected in 1546, and Surat, already a place of considerable trade, soon rose to be one of the greatest commercial cities of India. In 1612 the English established themselves there, in spite of the opposition of the Portuguese, and shortly after they were followed by the Dutch. These last were the busiest of the European traders. Surat at this time had commercial relations with western Europe, with the great cities of Northern India, with Arabia, Persia, the coast-towns of Southern India, Ceylon, and the East Indies, silk, cotton, and indigo being the most valuable exports. Here, too, the Mohammedan pilgrims of India were wont to embark for Mecca. Shortly after the middle of the 17th century the Mahrattas began to harass the city, and they pillaged it several times before the century ran out. But towards the end of the 17th century the commerce of Surat began to decline, Bombay gradually taking its place, especially after the East India Company transferred to that city the headquarters of their government. Just previous to this change Surat is believed to have had a population of 200,000. The place was transferred to English rule entirely in 1800, and for a time it had a revival of its old prosperity and became the most populous city in India. But by a quarter of a century later it had once more declined, and in 1837 was almost wholly ruined by a disastrous fire followed by a great flood. In 1858 it began once more to revive, and flourished during the period of the American civil war, its chief export being cotton. Pop. (1811) 250,000; (1847) 80,000; (1881) 109,840; (1891) 108,000. Cotton, silk brocade, and embroidery are manufactured.

Surbiton. See Kingston-upon-Thames.

Surcouf, Robert, a great French privateer, was born at St Malo, 12th December 1773, and died there, a taciturn but prosperous and corpulent boat-builder, in 1827. He preyed on the English shipping in the Indian seas during the long war, and showed extraordinary skill and courage. His greatest exploits were the capture of the Company's ships *Triton* of 800 tons (1785) and of the *Kent* (1800), almost at the end of her voyage from England to Calcutta. See Prof. J. K. Laughton's *Studies in Naval History* (1887).

Surd. See Irrational Numbers.

Surety. See Guaranty.

Surface-tension, in liquids, is that property in virtue of which a liquid surface behaves as if it were a stretched elastic membrane—say a sheet of india-rubber. We owe the idea to Segner (1751); but it was Young who, in 1805, first applied it successfully to the explanation of various physical phenomena, such as those of capillarity. The whole subject was subsequently developed in its complete mathematical form by Laplace and Gauss. The general description of the meaning of surface-tension has been given under Capillarity. Here we shall refer to a few other phenomena, which require for their elucidation the assumption of a tension existing in liquid surfaces. Pure water has the highest surface-tension of any ordinary liquid except mercury. If a little alcohol be dropped on the water, the surface-tension will be diminished there. The more powerful surface-tension over the pure water will show its superiority by pulling the alcohol over the whole surface until the surface is reduced to uniformity, and equilibrium produced. Again, a piece of camphor placed on water will dart from place to place in the most capricious manner. This is due to the irregular way in which the camphor dissolves in the water, so that the surface-tension is more weakened on one side than on the other. It is the action of surface-tension that draws out all over the surface any impurities that may settle on it; and hence arises the great difficulty of getting a clean water or mercury surface. Drops of liquid, free from all but their own molecular forces, assume spherical forms, this being the only shape consistent with equilibrium under the influence of equal surface-tension at all parts of the curved surface. Ripples on the surface of any liquid progress because of the action of surface-tension, which gives rise to an inward pressure on any convex surface. The laws governing the propagation of ripples on the surface of mercury have been recently studied by Professor C. Michie Smith and Lord Rayleigh. Some very instructive experiments may be made with soap-films (see SOAP-BUBBLES); while in cohesion figures we have some very exquisite phenomena, which have been closely studied by Tomlinson. These are produced by dropping a dark-coloured liquid into a transparent liquid of slightly smaller density. Ordinary ink dropped into water will serve the purpose very well, although better effects are obtained with a solution of permanganate of potash. As the drop meets the water-surface, the action of the surface-tension pulls the under surface of the drop outwards, and transforms the drop into a vortex ring, which slowly sinks through the clear fluid. As it so sinks it breaks up into smaller rings and shoots out fantastic ramifications of rare beauty. Ultimately, of course, under the influence of diffusion, the vortex motion decays and the dark liquid mixes with the clear liquid.

Surf-bird (*Aphriza virgata*), a plover-like bird found on the Pacific coasts of North and South America, akin to sandpipers and turnstones, and sometimes called Boreal Sandpiper.—The Surf-duck or Scoter is treated at SCOTER.

Surgeons, COLLEGE OF. The present 'Royal College of Surgeons of England' dates its origin from 1460-61, when Edward IV. 'did, at the supplication of the freemen of the mystery of barbers of the city of London using the mystery or faculty of Surgery, grant to them that the said mystery, and all the men of the same mystery of the said city, should be one body and perpetual community.' An act of 1511 prohibits any one from practising as physician or surgeon unless duly examined and admitted. Hence arose a company called the Surgeons of London. In 1540 the Company of Barbers of London and the Company of Surgeons of London were united; it was not till 1745 till the surgeons of London were by act of parliament separated from the barbers of London, and made a distinct corporation under the name of 'the Master, Governors, and Commonalty of the Art and Science of Surgery of London.' This company was dissolved, and in 1800 replaced by 'the Royal College of Surgeons of London.' A new charter granted in 1843 to the Royal College of Surgeons of England gave power to the council to elect not less than 250, nor more than 300, members of the college to be Fellows. By an addition to the charter, obtained in 1852, power was given to the council, subject to certain regulations, to appoint members of fifteen years' standing to the fellowship without examination. The college was likewise empowered to test the fitness of persons to practise midwifery and to grant certificates; in 1859 it was similarly authorised to grant certificates to dentists; finally, in 1888 certain additional powers were conferred, but the duty of examining in midwifery was withdrawn.

The government of the college is vested in a Council of twenty-four persons, including one president and two vice-presidents; and none but Fellows are eligible. There is a Board and a Court of Examiners for the fellowship, and examining boards for the membership. There are professorships of comparative anatomy and physiology, of surgery and pathology, and of dermatology, besides lectureships. A Hunterian Orator is appointed every second year. The museum of the College of Surgeons is incomparably the finest museum of its kind in the United Kingdom. The Hunterian Collection (see HUNTER, JOHN), which forms its basis, was purchased by a parliamentary vote of £15,000, and presented to the college in 1799. The original edifice in Lincoln's Inn Fields (the germ of the present pile of buildings) was completed in 1813. See the Calendar of the college.

THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH obtained their first charter in 1505, and had it confirmed by James IV. next year. For a century and a half the members of the craft were sole teachers and almost sole professors of the surgical art in Edinburgh. In 1694 they obtained from the town-council a grant of the bodies of convicts and foundling infants; in 1705 the professorship of anatomy was founded; about the same date botany, chemistry, and physic were taught; in 1726 the teachers of theory of physic, practice of physic, and chemistry in the college were constituted professors of medicine, and from this time the constitution of the medical school in the university dates; and in 1778 this college became a royal college. The present building, dating from 1832, possesses a fine museum. The college grants the diplomas of Fellow, Licentiate, Licentiate in Dental Surgery, and a diploma in public health; about 300 diplomas are granted annually.—The Royal College of Surgeons in Ireland was incorporated in 1786.

Surgery, or manual intervention, mediate and immediate, in all lesions or malformations of the human body, was already an art when medicine proper was but a phase of superstition. The earliest notices of it occur among the Egyptians, who, as we find represented on obelisk and in temple, practised incisions, scarifications, probably even amputation, long before the date of the Ebers papyrus (3500 B.C.). Castration (to supply eunuchs for the royal harem) was also a frequent operation. Preserved in museums may be seen surgical instruments contemporary with votive offerings of the remotest Egyptian epoch—lancets, tweezers, catheters, uterine specula, iron rods for the actual cautery, &c. Among other indications of early proficiency in ophthalmic surgery, couching cataract must have been known to them.

Jewish surgery, like Jewish medicine, was an importation from the Egyptians. The sexual regulations characteristic of the Jews affected their surgery, from simple circumcision up to the Cæsarean section, which very early in their history was practised on pregnant women in death as in life.

Without entering into the controversy as to the Greek origin of the Indian healing art, we find surgery enjoying high esteem among the Indians in very remote times. 'A physician who is no surgeon,' so ran their proverb, 'is like a bird with but one wing.' Surgical instruments skilfully made of steel, to the number of 127, still attest their proficiency in cutting and cauterising—the latter performed in observance of an aphorism quite Hippocratic in its ring—'What drugs and knives cannot cure may be cured with fire.' Their surgeons were trained to operate by practising not on animals or on the dead human subject, but on wax-covered boards, on beasts' skins, or on succulent plants and fruits. Hæmorrhage they checked by cold, by compression, and by styptics. The ligature they seem not to have known. Amputation was confined to the hand in cases of intractable hæmorrhage. Lips or surfaces of wounds they smeared with an arsenical salve. For intus-susception, volvulus, and such abdominal lesions they practised laparotomy, while fistula in ano (diagnosed by the speculum) they treated with the knife and corrosives. Lithotomy, in no case performed without the sanction of the rajah, they practised on the method (*sectio lateralis*) described by Celsus. The claim asserted for them of having independently of the Greeks devised the operation of rhinoplasty (constructing a nose from the neighbouring tissue —in this case from the cheek), and also that for cataract, has still to be made good.

As to the surgery of the other orientals we possess but obscure notices. Among the Persians we find Greeks in general practice under King Cambyses. The Chinese six centuries B.C. performed surgical operations (castration, for example) in the rudest fashion, and placed much reliance on acupuncture and the moxa. Japanese surgery betrays similar features.

In Greece surgery had attained high development before Hippocrates put medicine on a rational basis, and in the Hippocratic books we find a rich collection of surgical doctrine and practice drawn from centuries of experience. The treatise called *Iatreion* contains a description of the practitioner's room, its lighting, the instruments and appliances necessary, the duties of assistants, the accommodation of the patients, the position of the operator, the use of the hands, of water, of bandages, of sounds manufactured from tin or lead, &c. A full account of wounds and their treatment is given, hæmorrhage being arrested by cold, by compression, and styptics, the wounds themselves healed by primary union or through suppuration. Cataplasms cold and warm and plasters are also described in this connection. Lesion of the joints and its manifold consequences, and injuries to the *medulla spinalis* (paraplegia, &c.) are also dealt with. Dislocations and fractures have special treatises devoted to them. On the battlefield, on shipboard, in building operations, gymnastic and athletic contests the Greek surgeon lost no opportunity of perfecting the knowledge to which the latter-day world has surprisingly little to add. Medical scholarship has proved that many of the rarest forms of dislocation had not escaped Hippocrates. Even modern appliances were in great part anticipated by him—splints, for example, and bandages of various kinds. The gem of the Hippocratic surgery (according to Häser) is the treatise on injuries of the cranium—fractures, fissures, and contusions with or without depression. For such cases trepanning is the sovereign operation, to be performed as early as possible, less to get rid of effused blood, pus, &c. than, by removal of the injured osseous structure, to prevent inflammation of the scalp. This bold and circumspect practice creates surprise that the greater operations (extirpation of tumours, aneurisms, amputations, &c.) were ignored, till we remember that in their meagre knowledge of anatomy Hippocrates and his school were slow to risk section of the more important vessels and nerves. The removal of extremities which had become gangrenous shows again the Hippocratic surgery in a wonderfully favourable light. Hernias, hæmorrhoids, fistula are also described and treated with a judgment and skill remarkable for the time.

The post-Hippocratic school (its greatest surgeon being Praxagoras of Cos, noted for his cure of volvulus) has little to detain us; but the Alexandrians left a distinct mark on every branch of the healing art—surgery included. Our best knowledge of them comes from Celsus, who names as the most celebrated surgeon of Alexandria Philoxenus, a voluminous writer on the subject. Ammonius, the lithotomist, is another light of the school, lithotrity being his special contribution to practice.

Roman surgery can hardly claim M. Porcius Cato (234–149 B.C.) as more than a shrewd amateur who left some handy rules for the treatment of fractures, ulcers, nasal polypi, fistulæ, strangury, &c., having doubtless drawn on his experience as a slave-owning patrician. Archagathus (218 B.C.) was a regular practitioner, known, for his skilful handling of dislocations, fractures, and particularly wounds, as the 'Vulnerarius.' The senate confirmed the popular appreciation by providing him with a 'taberna' in a much frequented thoroughfare. But when from such practice he proceeded to operate with the knife his popularity fled, he was nicknamed the 'Carnifex,' and had to leave the city. Celsus, the patrician dilettante in medicine, is really the highest name in Roman surgery, though it is doubtful whether he ever operated. Of the eight books of his admirably written work the last two treat of surgery, including plastic replacement of defects in the outer ear, the nose, and the lips; lithotomy as practised on boys (a celebrated chapter); amputation, previously described by no other author; diseases of the bones, with the operation of trepanning, fractures simple and compound, and dislocations.

Galen, though a master of surgery and, before his settling in Rome under M. Aurelius, a practitioner of it, seems to have contributed nothing of his own to its doctrine or practice. As he found it (with some notable additions) it remained to the close of the Byzantine period. An intimate knowledge of its *modus operandi* during these centuries may be inferred from the collection of surgical instruments dug up at Pompeii and now on view at Naples. These are about 300 in number, consisting of some sixty different kinds: needles, hollow probes (straight, curved, and toothed), catheters, *specula vaginæ*, pincers, cauteries, bistouries, lancets, scissors, &c., mostly of bronze, many of the cutting ones of iron. To sum up: blood-letting was practised in antiquity by venesection, arteriotomy, cupping, and (later) by leeches. Hæmorrhage was checked by cold water, styptics, cauterising, ligature, and torsion—the two latter not mentioned by Hippocrates. the ligature being a device of the Alexandrians, as torsion was of the empire, after which time it fell into desuetude. The treatment of fractures and dislocations was practically the same from Hippocrates to Paulus Ægineta (650 A.D.). Trepanning received several modifications in practice up to Galen's time, while tracheotomy (introduced by Asclepiades, 1st century) was by Paulus restricted to cases of choking, when the deeper air-passages were free. The evacuation of pus in empyema, frequently mentioned by Hippocrates, was seldom performed in later times —Paulus recommending, instead of the knife, the application of the actual cautery to the wall of the thorax. The operation for hernia, perfunctorily dealt with by Hippocrates, had by the epoch of Celsus assumed the practical development in which it is found during the later empire, Heliodorus, under Trajan, being noted for his radical cure of the scrotal form. Lithotomy, in the Hippocratic period confined to specialists, was by the Alexandrian school raised to full surgical honours, to be supplemented under the Byzantine empire again by lithotrity. In Paulus we find a well-nigh exhaustive list of operations for disease or malformation of the genitals, even including syphilis (Häser), while rectal and anal affections (hæmorrhoids, fistula, &c.) were skilfully treated by Leonides (200 A.D.), who seems to have used the écraseur as well as the knife and the cautery. Large tumours in the neighbourhood of great vessels were untouched by Hippocrates or Celsus, though the latter makes mention of the surgical cure of goître. On the other hand, Leonides extirpated the cervical glands;

Antyllus (300 A.D.) tied their vessels above and below the point of section; and Paulus removed them by constricting them at their base by a ligature. Cancerous tumours after Celsus' time came within the category of *Noli me tangere*. Aneurisms find no place in Hippocrates, and Celsus refers only to the extirpation of varices. Antyllus seems first to have classified and dealt with the former—in true aneurism isolating the artery with a ligature above and below the sac, which he then opened and emptied. Amputation after Celsus is described by Archigenes, hæmorrhage being obviated by ligature of the great vessels or constriction of the limb. Flap-amputations were performed by Heliodorus and Leonides. Resection of the humerus, the femur, and the lower jaw proves (according to Häser) the high development to which surgery under the empire had attained, as also do the plastic operations which Antyllus describes with a fullness and freedom unknown to Celsus. A word may be added here for the medico-military service of that time, afloat and ashore, apparently quite as well organised as the combatant arm. Under the Byzantine emperor Maurice (582-602) the cavalry had an ambulance-company whose business it was to bring the severely wounded out of action, and who were provided with water-flasks and cordials to relieve the fainting.

The Arabs borrowed their surgery from the Greeks, chiefly from Paulus Ægineta, even more slavishly than their medicine. Their neglect of anatomy and their oriental repugnance to operations involving the effusion of blood serve to explain the fact that except Abulcasim (died 1122) they contribute no memorable name to this branch of the healing art.

Salerno did incomparably less for surgery than for medicine, partly because its representatives being mostly ecclesiastics held aloof from manual intervention, partly because its copyist monks reproduced from the classic authorities only the medical writings, leaving out those which had little or no interest for men of the cloister—gynæcology, surgery, pædiatry, &c. Still there is evidence that from the 10th to the first half of the 13th century they did take cognisance—theoretical at least—of wounds, burns, abscesses, fractures, dislocations, cancer, urinary calculi, and external applications.

Surgery continued to be looked down upon by physicians, all the more that the recently founded universities gave the latter the prestige of a culture denied to the adventurers who healed wounds, reduced dislocations, and set fractured limbs. Throughout the middle ages surgical literature seems to have shared the fortunes of medical literature—first the Greeks were in the ascendant, then their servile imitators the Arabs. The earliest mediæval writers in surgery were Italians, superseded in the 14th century by the French, while the same period witnessed the first English, Dutch, and German books on the subject. Guy de Chauliac, the highest name in that century, laboured to bridge the chasm between surgery and other branches of medicine. For all that, the mediæval surgeon in eastern Europe remained far behind his predecessors of the Roman and Byzantine empires. Traumatic hæmorrhage was arrested by the cautery and styptics, though the ligature had not quite fallen into oblivion. Operations for hernia and vesical calculus ranked highest in importance. Plastic surgery was a 15th-century revival of the ancient procedure, carried to rare perfection a century later by Tagliacozzi, again to sink into disuse. Similar fate befell the narcotic drinks (see ANÆSTHESIA), resuscitated in the same century, to dull the pain of surgical operations. The active principle of these had been inhaled even in the 13th century, and Guy de Chauliac also used opium internally for the same end.

With the 16th century we find surgery sharing the advance communicated to every art by the Renaissance, while its practitioners improved their social standing. In this the way had been led by Paris with her College of Surgeons (Collége de St Côme, 1279), which in the teeth of the university 'faculty' conquered the right to create licentiates in surgery. Other qualifying corporations (in London, for example, and Edinburgh) arose gradually on similar lines. But what crowned the recognition of surgery as a liberal profession was its steady progress as a beneficent public agent in peace as in war. Skill in treating gunshot wounds, in substituting the ligature for the cautery in amputations, and in dealing with the cutaneous affections due to pestilences like that of syphilis reinforced the claims to respect already established by fuller anatomical, chemical, and botanical knowledge. The powerful if eccentric genius of Paracelsus was signally instrumental in this direction; still more so the sound sagacity and nobly philanthropic inspiration of Ambrose Paré (1517-90). Galileo, Bacon, and Descartes revolutionised scientific method, among the fruits of which was Harvey's discovery of the circulation of the blood. With the diffusion of juster and more comprehensive notions of structure and function surgery took bolder and more effective flights, reaching her highest point in the 17th century under Richard Wiseman, 'the father of English surgery,' from whose *Seven Chirurgical Treatises* may be gathered the great accessions he made to sound practice, particularly in tumours, wounds, fractures, and dislocations. The lines of scientific surgery were now laid, and her advance became at once safer and swifter. In the 18th century Paris improved upon her Collége de St Côme by her Académie de Chirurgie, long the headquarters of the highest professional and literary culture. England contributed Cheselden and Pott, Scotland James Douglas, the three Monros, Benjamin Bell, and above all John Hunter to the promotion of a more enlightened practice, based on anatomical and physiological research. London, Edinburgh, and Dublin became centres of surgical education, which, by the admission of Häser, no continental school, not even Paris, could equal in the sovereign qualities of sagacity in diagnosis and assured boldness in operation. Prussia came far behind with her Collegium Medico-Chirurgicum in Berlin, and Austria only in 1780 and 1785 obtained the means of training surgeons of the higher grade, civil and military; while America by her school, under Dr Shippen in Philadelphia, laid the foundations of her subsequent and nobly sustained proficiency.

To the distinguished anatomists Mascagni and Scarpa in Italy, Breschet and Geoffroy St Hilaire in France, the brothers John and Charles Bell in Great Britain, the Meckels, Berres, Tiedemann, C. M. Langenbeck in Germany, seconded by physiologists like the Italian Panizzo, the Scottish Charles Bell, the English Marshall Hall, the French Magendie, Flourens, Duchenne, and Bernard, the German Prochaska, Purkinje, the brothers Weber, and Joannes Müller, surgery owes the mighty advance she made in the first decades of the 19th century. Of these pioneers some were themselves surgeons of the first rank, such as Scarpa and the brothers Bell; while among those who were equally great as teachers or writers and operators must be noticed Desault, Dupuytren, Roux, Delpech, and Lallemand in France; Lizars, Allan Burns, Liston, and Syme in Scotland; Abernethy, Astley Cooper, Brodie, and Lawrence in England; Warren, Mott, and Gross in America; Wattman, Siebold, Walther, Chelius, Langenbeck (already mentioned), Stromeyer, Graefe, and Dieffenbach in Germany; Kern, Pitha, and Linhart in Austria; Pirogoff and Szymanovsky in Russia. Anatomico-pathological museums and clinical instruction, displaying a wealth in object-lessons impossible before, are among the chief causes of the perfection to which the surgical profession is rapidly attaining. Add to these the introduction of anæsthetics, of the antiseptic ligature and dressing, of the galvano-cautery, of the transfusion of blood, and of the engrafting on patients of tissue taken from the healthy subject, and we can realise the revolution that has so altered the surgeon's art as to make its present position one of the greatest triumphs of human intellect, energy, and resource.

Häser's and Puschmann's works (the latter translated into English by Hare, Lond. 1892) give the fullest and most trustworthy account of the healing art, surgical as well as medical. Monographs like Wise's *History of Medicine among the Asiatics*, Young's *Annals of the Barber-Surgeons of London*, Struthers' *Historical Sketch of the Edinburgh Anatomical School*, and Cameron's *History of the Royal College of Surgeons in Ireland* may also be consulted. Special operations in surgery (Lithotomy, Ovariotomy, &c.) are dealt with under their respective heads, or in connection with the articles on such subjects as AMPUTATION, DISLOCATION, EYE, FRACTURE, HIP-JOINT, SHOULDER, &c. There are articles on CATHETER, OPHTHALMOSCOPE, STETHOSCOPE, TOURNIQUET, &c. See also Ashhurst's *International Encyclopædia of Surgery* (6 vols. 1882-86); and the articles in this work on the great surgeons. For contemporary surgery the annual summaries of the medical output of the year as given in the concluding numbers of the *Lancet* and *British Medical Journal* for each twelvemonth are full and detailed.

Suricate, a South African carnivore belonging to the family of the Viverridæ, of which the civet, genette, and ichneumon are representatives, but with much longer legs than these its kin. The body and head reach a length of 12 or 13 inches, the tail 6 inches. There are only four toes, and the claws are very long, suited for burrowing.

Surinam. See GUIANA (DUTCH). For the Surinam Toad, see AMPHIBIA, TOAD.

Surmullet. See MULLET.

Surname. See NAMES.

Surplice (Lat. *super pellicium*, 'above the robe of fur' worn by the monks from the 9th century), a white linen garment worn over the cassock by clerks of all degrees. Its most ordinary use is for the service of the choir, and it is also employed, along with the stole, by priests in the administration of the sacraments, and in preaching. The use of the surplice was strongly objected to by the Calvinistic and Zwinglian reformers on the Continent, and by the Puritans in England, who regarded this vestment as a relic of popery, and made it the subject of vehement denunciations. Ere ritualism became so common in England, no little stir used from time to time to be created by the use of the surplice, instead of the Gown (q.v.), in the pulpit, contrary to the more general practice in the Anglican Church. The length of the surplice varies, never in the Roman Church coming below the knees; the short Italian *cotta*, adorned with lace, dates from about the 17th century.—*Surplice-fees* are payments to the clergy by the laity when any sacred functions—baptisms, marriages, funerals—are performed for the latter's benefit.

Surrender. See CAPITULATION.

Surrey, an inland county in the south of England, is bounded on the N. by the Thames, which separates it from Middlesex, E. by Kent, S. by Sussex, and W. by Hants and Berks. Its maximum length from east to west is 39 miles; greatest breadth, 26 miles; and it contains 758 sq. miles, or 485,129 acres. Pop. (1801) 269,043; (1831) 485,700; (1861) 831,093; (1891) 1,730,871. Far-famed for the beauty of its scenery, Surrey is traversed from east to west by the North Downs (see DOWNS), which, near Titsey on the Kentish border, rise to the height of 880 feet; on the north side of this range the land slopes gradually to the banks of the Thames—though even there plenty of high ground is to be found, as Cooper's Hill, St George's Hill, Richmond Park, and Wimbledon Common—but on the south the descent is rugged and broken up before the level of the Weald is reached. South of the main range, and about 5 miles distant from Dorking, is Leith Hill (967 feet), the highest point in the county, whilst in the extreme south-west rises Hind Head (903 feet). From all these places, as also from many others—e.g. the Hog's Back, St Martha's Chapel, and Newland's Corner (both near Guildford), Box Hill, the downs above Reigate and Epsom, and at Virginia Water—glorious views are to be obtained, a noticeable feature in the landscapes being the prevalence of commons and heath-lands—the latter chiefly in the west—scattered throughout the county. Of rivers the most important are the Wey and the Mole, both tributaries of the Thames. The soil of the northern half of the county is fertile, especially in the vicinity of London, where large tracts are occupied by market-gardens and nursery-grounds, but in the centre and southern districts the land is of a poor quality, consisting mostly of sand and chalk; it is well wooded, box-trees especially growing in great profusion, and around Farnham some 2000 acres are under cultivation as hop-grounds. Croydon, Guildford, Kingston, and Reigate are—not reckoning the suburbs of London—the principal manufacturing centres and most important towns, near the last named also extensive beds of Fuller's Earth (q.v.) being found. The county is divided into fourteen hundreds, and since 1885 has returned six members to parliament; the county council consists of seventy-six members.

In history Surrey has played but a meagre part, the only incident of importance of which it was the scene, other than those noticed under Kingston, being a defeat of the Danes at Ockley in 851. Between the two last-named places traces of the old Roman road between London and Chichester are plainly visible, whilst on Wimbledon Common, Hascombe Hill, and near Aldershot are Roman encampments. Of buildings of an architectural or historical interest the castles of Farnham and Guildford and the ruined abbeys of Newark and Waverley most call for attention, whilst at Claremont, Oatlands Park, and Sheen (now Richmond), were royal residences; nor must mention be omitted of the quaintly-timbered old houses—many of them moated—abounding in the districts around Gomshall, Godalming, and Haslemere. Of Surrey worthies the best known are William of Ockham, Thomas Cromwell, Earl of Essex, Archbishops Abbot and Whately, Bishops Corbet and Wilberforce, Middleton and Oxenford (the dramatists), John Evelyn, Sir W. Temple, Viscount Bolingbroke, Admiral Lord Rodney, Banks (the sculptor), Gibbon, Horne Tooke, William Cobbett, Malthus, Herring (the animal painter), Michael Faraday, George Rennie, Sydney Herbert, Robert Browning, Hablot K. Browne, Albert Smith, Dr Jowett, Eliza Cook, Sant (the R.A.), Sir George Grove, Professors Cayley and Sidney Colvin, Dr Furnivall, Gilchrist (the biographer), and Miss Faithfull.

See works by Manning (3 vols. 1804-14), Allen (2 vols. 1829-30), Brayley (5 vols. 1841-48), Bevan (Stanford's series, new ed. 1891), and Murray's *Handbook to Surrey and Hants* (new ed. 1888); also *On Surrey Hills* (1892).

Surrey, HENRY HOWARD, EARL OF, poet, was born between 1516 and 1518, most probably in Suffolk, either at Framlingham or Tendring Hall, the eldest son of Thomas Howard (q.v.), who in 1524 succeeded as third Duke of Norfolk. In 1532 he was married to Lady Frances Vere, daughter of the Earl of Oxford, in the same year accompanied Henry VIII. to France, and afterwards spent about twelve months in study at Paris in company with Henry's natural son, the young Duke of Richmond, who was affianced to his only sister, but died an untimely death in 1536. Surrey's eldest son Thomas was born that same year, and it is interesting that the child's nativity, which still exists, foretold dark disaster to the father. It was soon after this that his romantic passion for the fair but disdainful Geraldine awoke, unless she is to be relegated to the domain of fancy in the same sense as Héloïse, Petrarch's Laura, and Tasso's Leonora. It seems certain, however, that if she had real existence she was the Lady Elizabeth Fitzgerald, the second of the three daughters by his second marriage of Gerald, ninth Earl of Kildare. But the story is surrounded with difficulties, and we are not helped by Thomas Nash's absurd account (*Unfortunate Traveller*, 1594) of how Surrey traversed Italy like a knight-errant for his mistress' sweet sake. His second son, afterwards Earl of Northampton, was born in 1539. In 1542 he was made a Knight of the Garter. Later in the same year he lay some time in the Fleet for challenging a gentleman with whom he had quarrelled, and next year he was again committed for roystering and breaking windows in the streets at night. Soon released, he went to serve in the camp before Landrecy near Boulogne, and returned in winter to complete his beautiful seat of Mount Surrey near Norwich. It was at this time that he admitted to his household the physician Hadrian Junius and the poet Churchyard. Again in 1544 Surrey went to France as marshal of the invading army, and distinguished himself at the siege of Montreuil, being severely wounded in the attempted storming (19th September). Again next year we find him holding command at Guisnes and at Boulogne, and defeated by a superior French force in the beginning of January, for which he was soon superseded by the Earl of Hertford, who, as uncle to the heir to the throne, looked forward to a regency on the king's death, and at once feared and hated the Norfolk party. For his bitter speeches against Hertford Surrey was imprisoned at Windsor in July, and on the 12th December was, like his father, committed to the Tower on a charge of high-treason. His offence was merely that he had assumed the arms of his ancestor Edward the Confessor, in conjunction with his own proper arms, a thing which by all the laws of heraldry and common usage he was perfectly entitled to do, and which, moreover, had been specially allowed the Duke of Norfolk by Richard II. His father's mistress and his own sister gave evidence against him, and, though he defended himself with singular ability at his trial at the Guildhall on the 13th January 1547, he was found guilty by the jury, condemned to death, and beheaded eight days later, 21st January 1547. His body was first buried in All Hallows-Barking, Tower Street, but was removed by his son, the Earl of Northampton, to Framlingham Church, where it rests under a stately monument of black and white marble.

Surrey's character would seem to have been much less amiable than it appeared to his eulogist, Dr Nott. He was proud, headstrong, and imprudent, and his unkindness to his mother remains a blot upon his memory, however unworthy of respect she may have been. His poems seem to have circulated freely in manuscript during his lifetime, but were not printed till 1557, when they appeared, together with poems by Wyatt and others, in *Tottel's Miscellany* (ed. Arber, 1870). They consist of sonnets, lyrics, elegies, translations, paraphrases of the Psalms of David and Ecclesiastes, besides translations in good blank verse—the first in English—of the second and fourth books of Virgil's *Æneid*, the last not given in Tottel. As a poet he shows grace, delicacy, a quick eye for the beauties of nature, and a sensitive ear to the harmonies of versification. His love-poetry follows Petrarch too closely, yet not without a truth and genuineness of feeling of its own. He was not only the first in English to employ the sonnet, but within his range he had mastered the difficulties of that artificial form.

See the edition of Surrey and Wyatt in two goodly quartos, by Dr G. F. Nott (1815–16); of Surrey alone, in the 'Aldine Poets' (1831; reprint 1866).

Surtees, ROBERT, born at Durham, 1st April 1779, graduated B.A. from Christ Church, Oxford, in 1800, and, after less than two years at the Middle Temple, in 1802 came into his paternal estate of Mainsforth, near Bishop Auckland. Here till his death on 11th February 1834 he largely devoted himself to the compilation of his *History and Antiquities of the County Palatine of Durham* (vols. i.–iii. 1816–23), to vol. iv. of which (1840), completed by the Rev. James Raine, a memoir by George Taylor is prefixed. To Scott's *Minstrelsy* Surtees contributed two 'ancient' ballads he himself had made—*Barthram's Dirge* and *The Death of Featherstonhaugh*. The Surtees Society, founded in 1834 for the publication of unedited MSS. relating chiefly to the northern counties, issued its seventy-third volume in 1884.

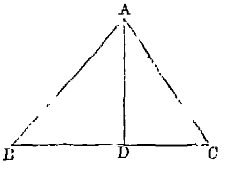
Surturbrand, a kind of Lignite (q.v.) found in the north of Iceland, and used for fuel, has a great resemblance to the black oak found in bogs.

Surveying. Land-surveying may be considered the earliest practical application of the art of geometry or earth measurement, and must have been in some more or less rude form coeval with agriculture and the division or appropriation of the soil. In Rome surveying was considered one of the liberal arts, and the measurement of lands was entrusted to public officers who enjoyed certain privileges; and it is probable that the system of measurement practised by them was very similar to our plain surveying with the chain and cross-staff of the present day, and has been handed down to us through the feudal period. An examination of ancient records and title-deeds will show that both areas and boundary lines of the different enclosures forming fields, hundreds, town-lands, &c. are often laid down with much accuracy.

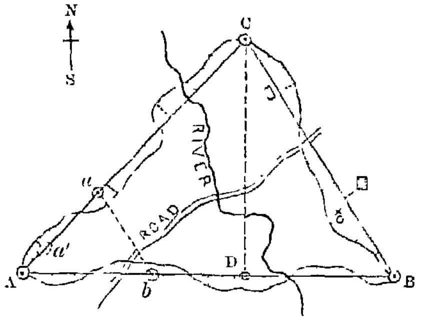
Land-surveying may be considered under the following heads: (*a*) Plain surveying with the chain, and without the aid of angular instruments, except the cross-staff or fixed angle of 90°; (*b*) modern engineering surveying, in which angular instruments are used; (*c*) coast and military surveying; (*d*) trigonometrical surveying.

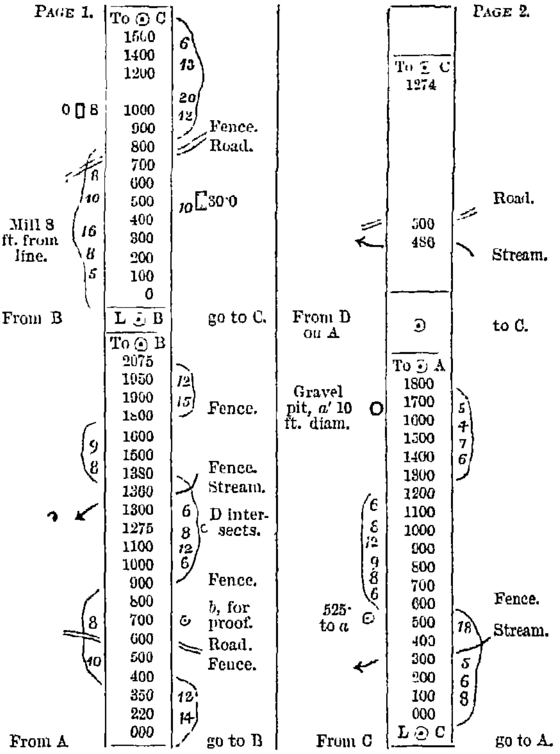
The fundamental rule of every description of land-surveying, from the humblest attempt to lay down an irregular garden-plot to the trigonometrical survey of a large extent of the earth's surface, when the aid of the most refined improvements of modern science is indispensable, is simply to determine three elements of a triangle, and thence to calculate its area.

In plain surveying with the chain the three sides of the triangle, ABC, are supposed to be accessible, and are carefully measured on the ground, and then laid down or platted to scale on paper, when an accurate figure of the triangle will be obtained, on which the length of the sides can be marked. To get the area, however, it will be necessary to



determine the length of the perpendicular line AD, and this is usually done (when possible) on the ground by means of a simple instrument called a cross, which consists of two sights or fine grooves at right angles to each other; which being placed on the line BC (keeping B and C visible in one of the sights), nearly opposite the angle A, is moved gradually till the angle A is intersected by the other sight. The line AD can also be laid down on the drawing, and its length found by scale and afterwards verified on the ground, or it may be at once laid down on the ground by the use of the chain alone. An improved reflecting instrument, called an optical square, is also often used for this purpose. Any boundaries along the lines or sides of the triangle, ABC, can be determined by the use of offsets or insets, as they occur on right or left of line. No matter what the form of the surface to be surveyed may be—polygon, trapezium, or trapezoid—it may thus be determined by a judicious subdivision into triangles; and when the survey is not of a very extended nature or character, and when no serious obstructions exist, chain surveying is both accurate and expeditious, especially if proof or tie lines are properly introduced for the purpose of testing the accuracy of the work.





The line *ab* may be similarly booked and platted.

In every description of surveying it is best to make the original triangle as large as possible, and to work from a whole downwards rather than build up a large triangle by the addition of several small ones. It would be impossible here to lay down rules to meet the many difficulties which arise in the practice of surveying; indeed the best test of a good surveyor is the ease with which he will overcome local obstructions which appear almost insurmountable to a novice, or even to a theoretical surveyor with little field practice. Where buildings or other impediments are found in the measurement of a straight line, they are generally passed by the erection of short perpendiculars sufficient to clear the obstacles, and a line parallel to the original measured as far as they exist, when the original line can be again resumed. Differences of level occurring in measuring a line where no instruments are used are generally compensated or allowed for by the judgment of the surveyor.

In registering the dimensions taken on the ground, such as sides of triangles, offsets, intersections of roads, fences, &c., and everything necessary to make a perfect delineation or plan of the surface, surveyors use what is called a field-book, the mode of keeping which varies very much with individual practice. Some surveyors use hand sketches or rough outlines of the form of the ground, and mark the dimensions on them, while others use the ordinary form of field-book, or a combination of the two methods, which perhaps is the best when any difficult complications happen on the ground, such as the frequent occurrence of buildings, enclosures, water, &c. along the line. In the ordinary field-book the centre column, commencing from the bottom, represents the length of any line or side of a triangle, and the figures in the column the distance at which the offsets to the right or left are taken, or where roads, streams, fences, &c. cross the line, or buildings adjoin the same. We give herewith the field-book of the assumed survey of the triangle ABC, with the different offsets and insets on its sides, and where roads, fences, streams, &c. cross them, the detail of which can be obtained by subdividing the triangle into smaller internal ones. The figure can thus be laid down from the book, and its area calculated by the formula $\frac{AB \times CD}{2}$, and the offsets and insets calculated, and added or deducted.

Ponds, plantations, and enclosures of different kinds may be surveyed with a chain, especially if their form be such that they can be conveniently included in the area of a triangle, the correctness of which being proved by proper tie-lines, the form, area, &c. may be ascertained by offsets, or rather insets from the sides.

See Ordnance Survey, Levelling, Mensuration, Theodolite, Contour, &c.; and for the United States Coast Survey, see Chart.

Surya, in Hindu Mythology, the sun-god.

Sus, (1) a river and district of Morocco (q.v.), between the Atlas and the Anti-Atlas.—(2) A port of Tunis, 75 miles SE. of the capital. Pop. 8000.

Susa, the same as the Shushan of Daniel, Esther, &c., a town of Persia, identified with the modern Sus, anciently the capital of Susiana (the *Elam* of Scripture, mod. *Khusistan*), and one of the most important cities of the old world. Its foundation is ascribed by some ancient writers to Darius Hystaspes, by others to Memnon, the son of Tithonus; and its name, together with its ground-plan, is traced on Assyrian monuments of the reign of Assur-bani-pal (about 660 B.C.). At the time of Daniel's vision 'at Shushan in the palace' it was under Babylonian dominion, but it was brought by Cyrus under Persian rule; and the Achæmenian kings raised it to the dignity of a metropolis of the whole Persian empire, having there a strong citadel and one of their treasure-houses. At the Macedonian conquest Alexander is reported to have found in it vast treasures, together with the regalia. On Babylon becoming the principal city of Alexander and his successors, Susa gradually declined, but seems still to have contained enormous wealth when it fell into the hands of Antigonus (315 B.C.). It was attacked by Molon in his rebellion against Antiochus the Great, and held out bravely for a long time against the Arab invaders at a later date. They, however, destroyed the fortifications. The ruins of the ancient city, the palace described in Esther among them, cover a space of about three square miles. The principal existing remains consist of four spacious artificial platforms above 100 feet high. Traces of a gigantic colonnade were laid bare by Mr Loftus, with a frontage of 343 feet and a depth of 244. Cuneiform inscriptions exist, together with many relics similar to those found at Persepolis. The 'tomb of Daniel' shown near Susa was a place of pilgrimage previous to the Arab conquest. See books by Williams, Loftus, Churchill, and Dieulafoy, all of whom have explored the site.

Susa, a city of Northern Italy, on a tributary of the Po, at the foot of the Cottian Alps, 32 miles by rail W. of Turin. It has a cathedral (1029), and a triumphal arch erected by the Romanised Segusian chief to Augustus in 8 B.C. The people (3305) grow fruit and grapes, and carry on iron, leather, and silk industries.

Susannah, HISTORY OF, *The Judgment of Daniel*, also *Susannah and the Elders*, are the different titles of a well-known story, which forms one of three apocryphal additions to the book of Daniel; the other two being *The Song of the Three Holy Children* and *The History of Bel and the Dragon*. It relates how Susannah, the wife of Joacim, and daughter of Hilkiah, celebrated alike for her beauty and her virtue, was falsely accused of adultery by two of the elders, whose own unchaste proposals she had spurned; and how, being condemned to death on their evidence, she was saved by the wise young Daniel, who made the elders confound each other in separate examination, and doomed them to the same fate they had designed for her. In most MSS. this story precedes the first chapter of the Book of Daniel, and so we find it in the old Latin and Arabic versions; but the Septuagint, the Vulgate, the Complutensian Polyglot, and the Hexaplar Syriac place it at the end of the present book, and reckon it as the 13th chapter. There are two Greek versions varying considerably—that of the LXX. and that of Theodotion. There is no satisfactory evidence that it ever had a Hebrew or Aramaic original at all. Africanus had a controversy with Origen on the authenticity of *Susannah* and *Bel and the Dragon*, and pointed out that their original could only have been a Greek one, as the example of paronomasia in the words of Daniel depended on the Greek. Porphyry based his attack on Daniel partly on the Greek origin of Susannah. Jerome is careful to distinguish it from the rest of Daniel, as not possessing the authority of Scripture. At the same time the story is used by Hippolytus, Origen, Tertullian, Ambrose, Gregory Nazianzen, and Chrysostom. The object of the story may have been to correct the procedure of the Sanhedrim, by insisting on the proper use of evidence and the examination of witnesses.

See Dr Brüll, 'Das apokryphische Susanna-Buch,' in his *Jahrbücher für Jüdische Geschichte und Literatur* (Frankf. 1887); also the Introduction to the Rev. W. R. Churton's edition of the *Apocrypha* (1884), and that in Dr Wace's *Commentary on the Apocrypha* (1888).

Suspended Animation, the temporary cessation of the outward signs and of some of the functions of life, is treated under various heads in this work. In men it may be due to Asphyxia, Drowning, Strangulation, &c. See also CATALEPSY, COMA, INSANITY, SLEEP, DEATH, and for premature burial, BURIAL. For phenomena of this kind in the lower animals, see LIFE, DESICCATION, HIBERNATION, LATENT LIFE, ROTATORIA, &c.

Suspension Bridge. See BRIDGE.

Susquehanna, an American river, the North Branch (350 miles) of which has its origin in Schuyler Lake, in central New York, and the West Branch (250 miles) in the Alleghany Mountains. These two unite at Northumberland, Pennsylvania, and the river thence flows south to Harrisburg, and then south-eastward into Maryland, and so to the north end of Chesapeake Bay. Length, 150 miles; chief tributary, the Juniata. It is a shallow, rapid, mountain river, with varied and romantic scenery, and is of use mainly for floating timber. On its banks Coleridge and Southey proposed to found their 'pantisocracy.'

Sussex, a maritime county in the south of England, washed on the south-east and south for 91 miles by the English Channel, and elsewhere bounded by Hampshire, Surrey, and Kent. It has an extreme length from east to west of 76 miles, an extreme width of 27, and an area of 1464 sq. m., or 936,911 acres. From the Hampshire border, near Petersfield, to Beachy Head (q.v., 575 feet) the county is traversed by the chalky South Downs, whose highest point is Ditchling Beacon (858 feet), and whose northern escarpment is steep, but leads down to the fertile and richly wooded Weald. Beyond this again, in the north-east, is the Forest Ridge (804 feet). A very productive tract, 2 to 7 miles broad, extends westward from Brighton along the coast to the Hampshire boundary; in the south-east are rich marsh-lands, affording excellent pasture. The chief streams, all unimportant, are the Arun, Adur, Ouse, and Rother. Rather more than two-thirds of the entire area is in cultivation; and 177 sq. m. (second only to Yorkshire) are occupied by woods—in the Weald, St Leonards and Ashdown Forests, &c. The Downs (q.v.) are clothed with a short, fine, and delicate turf; and here and elsewhere more than half a million of the well-known Southdown sheep are grazed, the live-stock also including some 25,000 horses and 113,000 cattle. Sussex was once the chief seat of the iron trade, when wood was used for smelting, and its last furnace was not blown out till 1809; to-day the manufactures are not important. The county, which contains six 'rapes,' 68 hundreds, and 317 parishes, has since 1885 returned six members to parliament. Brighton and Hastings are parliamentary and Arundel, Chichester, Eastbourne, Lewes, and Rye municipal boroughs; whilst Newhaven, Worthing, Seaford, Littlehampton, and

Bognor also deserve mention. Pop. (1801) 159,471; (1841) 300,075; (1881) 490,505; (1891) 550,442. Sussex contains the landing-place of Cæsar (55 B.C.) either at Pevensey or near Deal; of Ælla (477 A.D.) at Keynor, near Chichester, from whose subjects, the South Saxons, the county derived its name; and of William the Conqueror (1066) at Pevensey, as well as the battlefields of Hastings and Lewes. The antiquities include a British camp at Cissbury, Roman remains at Pevensey and Bognor, a dozen mediæval castles (Arundel, Bodiam, Hurstmonceaux, Hastings, Bramber, &c.), and nine or ten religious houses (Lewes, Battle, &c.). Cobden, Collins, Fletcher, Otway, Sackville, Selden, and Shelley have been among the eminent natives; and Sussex also has memories of Chillingworth, Lyell, Archdeacon Hare, John Sterling, Cardinal Manning, and Titus Oates.

See works by T. W. Horsfield (2 vols. Lewes, 1835), M. A. Lower (3 vols. 1865-70), C. W. D. Parish (*Domesday Book in relation to Sussex*, 1886), and G. F. Chambers (3d ed. 1891).

Sustentation Fund. See FREE CHURCH.

Sutherland, a maritime county in the extreme north of Scotland, is bounded W. and N. by the Atlantic, E. by Caithness, SE. by the North Sea, and S. by the Dornoch Firth and by Ross and Cromarty. Measuring 63 by 59 miles, it has an area of 2126 sq. m., or 1,360,459 acres, of which 47,633 are water and 12,812 foreshore. The Atlantic coasts, deeply indented by sea-lochs, are bold and rock-bound, in Cape Wrath (q.v.) attaining 523 feet; the south-eastern seaboard is comparatively flat. On the Caithness boundary rise the Hill of Ord (1324 feet) and Cnoc an Eireannaich (1698); but the mountains of Sutherland are all in the west—Benmore Assynt (3273), Coniveall (3234), Bendibrick (3154), Ben Hope (3040), Foinaven (2980), Canisp (2779), and Suilven or the Sugar-loaf (2399). The Oykell, tracing the Ross-shire boundary, and falling into the Dornoch Firth, is the longest stream (35 miles); and of over 300 lochs and tarns the largest are Lochs Shin (16 × 1½ miles) and Assynt (q.v., 6¾ × ¾). The geology is of great interest—Archæan gneiss predominating in the west, then Silurian, and then Old Red Sandstone. Coal has been mined at Brora off and on since 1573; and a find of gold at Kildonan in 1868 for a time caused a rush of 'diggers.' The total percentage of cultivated area is only 2·9, in spite of costly reclamations carried on by the Duke of Sutherland, who is by far the largest proprietor—so costly indeed that during 1853-82 the expenditure on his estates exceeded the income derived from them by nearly a quarter of a million sterling. The live-stock includes over 10,000 cattle and 200,000 sheep; and the deer-forests, grouse-moors, and fishings (especially good for trout) attract many sportsmen. The climate varies much, and also the rainfall, which increases westward from 32 to 60 inches. Sutherland returns one member to parliament; its county town is Dornoch (q.v.). Pop. (1801) 23,117; (1851), 25,793; (1881) 23,370; (1891) 21,949. The Northmen, who down to the 12th century often descended on Sutherland and pillaged it, called it the 'Southern land,' as lying to the south of the Orkney and Shetland islands. An earldom of Sutherland was held from about 1228 by the Freskin family, but passed by marriage in 1514 to the Gordons, whose line also ended in an heiress in 1766. She married in 1785 George Granville Leveson-Gower, second Marquess of Sutherland, who in 1833 was created Duke of Sutherland. To him was due the credit or discredit of the so-called 'Sutherland clearances' (1810-20), by which the small tenants, living wretchedly in the interior, were compelled to remove to the coast or to the valleys near the sea.

See Sir Robert Gordon's *History of the Earldom of Sutherland* (1813), Bishop Pococke's *Tour in 1760 in Sutherland and Caithness* (1888), C. W. G. St John's *Tour in Sutherlandshire* (2 vols. 1849; new ed. 1884), A. Young's *Angler's Guide to Sutherland* (1880), A. Mackenzie's *History of the Highland Clearances* (1883), and J. E. Edwards-Moss's *Season in Sutherland* (1888).

Sutherland Falls. See NEW ZEALAND, Vol. VII. p. 487.

Sutlej, or SATLAJ (anc. *Hyphasis* or *Hesidrus*), the eastmost of the five rivers of the Punjab, rises in the sacred lakes of Manasarowar and Rakas-tal in Tibet, at a height of 15,200 feet, and near the sources of the Indus and the Brahmaputra. It flows at first north-west, but turns westward to cut its way through the Himalaya Mountains, in the course of which passage it drops to about 3000 feet. After entering British territory it pursues a general south-western direction, receives the Li or river of Spiti, passes round the Siwalik Hills, picks up the waters of the Beas and the Jhelum-Chenab, and after flowing 900 miles in all joins the Indus at Mithankot, south of Multan. Not far from Jullunder it is crossed by a magnificent iron bridge, 2½ miles long, carrying the Sind, Punjab, and Delhi Railway, and near Bhawalpur, just before its confluence with the Jhelum-Chenab, is spanned by the bridge of the Indus Valley Railway.

Sutler. See CAMP FOLLOWERS.

Sûtra, in Sanskrit Literature, the technical name of aphoristic rules, and of works consisting of such rules. In such aphorisms the groundworks of the ritual, grammatical, metrical, and philosophical literature of India are written. See SANSKRIT, VEDA, PITAKA.

Suttee (an English spelling of the Sanskrit *satî*, 'a virtuous wife'), a usage long prevalent in India, in accordance with which on the death of her husband the faithful widow burned herself on the funeral pyre along with her husband's body, or, if he died at a distance, was burned on a pyre of her own. The practice was in use in India as early as the times of the Macedonian Greeks, and was based by Hindus on various of their sacred books and laws (the Brahma-Purána, the Vyása, &c.). But the researches of European scholars have made it absolutely certain that no countenance to this barbarous rite can be derived from the oldest and most sacred scriptures. The few passages professedly cited from the Vedas have been proved to be misquoted, garbled, or wholly false; and the laws of Manu are silent on the subject. Nevertheless self-immolation, though not enforced on an unwilling victim, and not practised except in certain castes and families of old descent, was almost made incumbent on well-born widows by force of public opinion, unless they were willing to risk their own happiness here and hereafter. The rite was no doubt entirely alien to pure Brahmanism, and was derived from a belief common to many savage races at all times of the world's history, that it was well to send wives, slaves, horses, favourite weapons, &c. along with a great man into the other world, by burying them with him, burning or slaying them at his tomb. In 1823 there were 575 widows burned in Bengal Presidency, 310 within the jurisdiction of the Calcutta court. Of these 109 were above sixty years of age, 226 from forty to sixty, 208 from twenty to forty, and 32 under twenty (Max-Müller, *Biographical Essays*, 1884). When Lord William Bentinck resolved to put an end to this hideous sacrifice he was met by fierce opposition both from natives and Europeans, though backed by some official and public opinion. And on the 4th December 1829 he carried the regulation in council which made all who encouraged suttee guilty of culpable homicide. The enactment soon told on the custom. The prohibition of suttee is a feature of treaties between the imperial government and the native states; and though occasional cases of suttee occur in native territory, and rarely within the British area (on the death of Sir Jung Bahadur, prime-minister of Nepal, in 1877 several of his wives immolated themselves), suttee may be said to be practically extinct.

Sutton Coldfield, a municipal borough of Warwickshire, 8 miles NE. of Birmingham by rail, with an old Early English church, extended in Henry VIII.'s reign, and a new aisle built in 1880. Henry VIII. granted a charter in 1529, and the manor was entirely transferred to the corporation; a new charter was granted in 1885. Agriculture is the chief occupation of the neighbourhood; the borough is rapidly becoming a residential suburb of Birmingham. The picturesque Sutton Park (3500 acres), belonging to the inhabitants, is a favourite resort of picnic parties. Pop. (1891) 8686.

Sutton-in-Ashfield, a town of Nottinghamshire, 3 miles SW. of Mansfield. It has a fine church (1390; restored 1868), hosiery manufactures, and neighbouring coal-pits and lime-works. Pop. (1881) 8523; (1891) 10,563.

Sutton-on-Sea, a seaside resort on the coast of Lincolnshire, much frequented by the people of the big towns of Nottingham, York, Lancaster, and Leicester, is 28 miles NE. of Boston by rail. It has a fine stretch of broad, firm sand, and close by a submerged forest may be seen at low tide.

Suture (Lat. *sutura*, 'a seam') is a term employed both in Anatomy and Surgery. In anatomy it is used to designate the modes of connection between the various bones of the cranium and face. A suture is said to be *serrated* when it is formed by the union of two edges of bone with projections and indentations (like the edge of a saw) fitting into one another. The coronal, sagittal, and lambdoidal sutures (see SKULL) are of this kind. A suture is termed *squamous* when it is formed by the overlapping of the bevelled (or scale-like) edges of two contiguous bones.

In surgery the word suture is employed to designate various modes of sewing up wounds, so as to maintain the opposed surfaces in contact. The materials most commonly used are silk, silver wire, horsehair, and specially prepared catgut. As it may fall to the lot of any person, on an emergency, to have to sew up a wound, the following general rules, applicable to all forms of suture, should be attended to. In passing the needle, the edges of the wound should be held in contact with the forefinger and thumb of the left hand; and the needle should penetrate the surface at about an angle of 50° (rather more than half a right angle), and should, at least, pass through the whole thickness of the skin at each stitch. The distance from the edge of the wound at which each stitch should enter and leave the skin must vary with the depth of the wound; but there should never be less than the eighth of an inch between the margin of the wound and the entrance or exit of the needle. Sutures should not include vessels, nerves, muscles, or tendons. The line of the thread should cross that of the wound at right angles. For incised wounds on the surface of the body, when the edges can only be transfixed from the cutaneous surface, or when the opposite margins can both be traversed by one plunge, a curved needle (such as a common packing-needle) is most convenient, whereas a strong straight needle is more convenient for the completely free margins of extensive wounds, such as are left after amputation. Fig. 1 represents various forms of needles used by surgeons; fig. 2 shows the *twisted suture*, as used in the operation for hare-lip, in which the wound is transfixed by pins, around which, beginning with the uppermost, a thread is twisted, in the form of the figure 8.

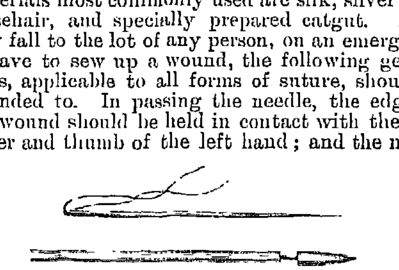


Fig. 1.

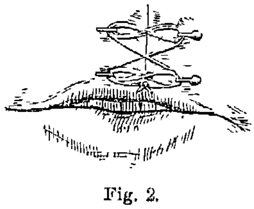

Fig. 2.

Suvalky (*Ssuwalki*), a Polish town, capital of a Russian government, 48 miles NW. of Grodno. Pop. 19,367. For the area and population of the government, see RUSSIA.

Suvóroff, or SUWARROW, ALEXANDER VASILIEVITCH, a Russian general, was born at Moscow on 24th November 1729, his father, of Swedish descent, being a general and senator. Small of stature and sickly in appearance, Alexander was a devoted student, and whilst still a boy acquired an excellent knowledge of languages; but his heart was fired with the passion of military glory, Cæsar and Charles XII. of Sweden being the heroes of his imagination. He entered the army as a private when seventeen, but advanced rapidly in rank after the Seven Years' War, in which he greatly distinguished himself at Kunersdorf (1759) and Reichenbach (1761), and after the Polish war of 1768–71, in which his impetuous bravery, and the boldness and celerity of his attack, brought him prominently forward. From this time to the end of his life he was almost constantly in the field. In 1773 he passed from Poland to the south of Russia to war against the Turks; in 1774 he put an end to the insurrection of Pugatcheff; and in 1780 he crushed the revolt of the Kuban Tartars and other Caucasian tribes. He covered himself with glory in the Second Turkish War, defeating the armies of the sultan at Fokshani (1789) and at the river Rymnik, and storming the strong fortress of Ismail. In the Polish war of 1794 Suvóroff captured Praga, and so compelled the surrender of Warsaw. On the accession of the Emperor Paul he was for a time sent into retirement; but shortly afterwards Paul recalled him and ordered him (1799) to Italy to assist the Austrians in opposing the French. As usual he won battles, defeating Moreau on the Adda, Macdonald at the Trebbia, and Joubert at Novi. Then he was directed to cross the Alps and unite his forces with Korsakoff for the purpose of sweeping the French out of Switzerland. After a terrible march, with fearful sufferings and heavy losses, he found, on descending towards the canton of Schwyz, that Masséna had defeated Korsakoff, and being himself too weak to attack he barely managed to escape over the mountains into Austria. On his return to Russia he was overtaken by death at St Petersburg on 18th May 1800. Suvóroff was a little man (5 feet 4 inches), with a wrinkled face and a stooping attitude; yet he was strong and healthy, and inured to hardship—he lived like a common soldier, and slept by preference on a truss of hay. Of great intelligence, he was a constant reader, even when on campaign, and a clever linguist. The idol of his soldiers, who loved to call him 'Father Suvóroff,' he was never defeated, and only once in his life acted on the defensive. He had a superb faith in his own star, and trusted to the inspiration of the moment, to rapidity of movement, and to boldness and dash in making the onset. Notwithstanding the terrible loss of life that attended his storm of Ismail (26,000 Turks were killed) and of Praga at Warsaw (where 15,000 Poles were massacred), he is stated to have been averse to shed blood, and to have been even humane and merciful. In his manners he was extravagantly eccentric, brusque and curt in speech, laconic in his despatches, and sarcastic to all who incurred the contempt of the soldier and man of action. Byron's description of him in *Don Juan* is as inaccurate as the biographies written by his enemies, the French. See Life by Lieut.-Col. Spalding (Lond. 1890).—The name of Suwarrow Islands belongs to a part of the Manihiki (q.v.) group.

Suwanee River rises in southern Georgia, in the Okefinokee Swamp, and flows in a winding, generally south-south-west course through Florida into the Gulf of Mexico.

Suzdal, a small Russian town (7000), 12 miles N. of Vladimir, once capital of an important Russian principality. See RUSSIA, pp. 42, 43.

Suzerain, a feudal lord. The term was applied less to the king than to his vassals who had sub-vassals holding of them. In modern times suzerainty indicates a degree of formal or real authority varying from the relation of the Ottoman porte to the tributary states, to that of the British crown to the Transvaal or South African Republic.

Svas'tika, a religious symbol used by early races of Aryan stock from Scandinavia to Persia and India. It consists of a Greek cross, either enclosed in a circle the circumference of which passes through its extremities ⊕, or with its arms bent back thus 卍, and was intended to represent the sun, being found invariably associated with the worship of Aryan sun-gods (Apollo, Odin). Similar devices occur on the monumental remains of the ancient Mexicans and Peruvians, and on objects exhumed from the prehistoric burial-mounds of the United States. See CROSS.

Sveåborg, a fortress in Finland, sometimes called 'the Gibraltar of the North,' protects the harbour and town of Helsingfors (q.v.), from which it is 3 miles distant. The fortifications, which were planned and first prepared by Count Ehrensvärd in 1849, have been already described under Helsingfors. It only remains to add here that at Sveåborg there are an arsenal, docks, slips, and a monument to the 'father' of the fortress. Pop. 1000, excluding the garrison. The fortifications were betrayed into the hands of the Russians by the Swedish commandant in 1808.

Svendborg. See FÜNEN.

Svendsen, JOHAN SEVERIN, composer, born at Christiania, 30th September 1840. He studied at Leipzig, Paris, and in Italy, conducted concerts in his native town, and in 1883 became master of the Chapel Royal at Copenhagen. His works comprise symphonies, an overture, and quartetts, quintetts, and concertos for strings.

Svenigorodka, a town in the Russian province of Kieff, 100 miles S. of Kieff. Pop. 11,562.

Swabia (Ger. *Schwaben*), or SUABIA, an ancient duchy in the south-west of Germany, stretching from Franconia to Helvetia (Switzerland) and from Burgundy and Lorraine to Bavaria. It was so named from the Germanic Suevi, who drove out the Celtic inhabitants of the region in the 1st century B.C. With those conquerors the Alemanni, who invaded that part of Europe in the end of the 5th century, became amalgamated; and from that time there were dukes in Swabia, except for the period 746-919. During the reigns of the Hohenstaufen emperors, who were natives of Swabia and almost invariably conferred the ducal dignity on some relative of their own house, this duchy was the most rich, most civilised, and most powerful country of Germany, and the ducal court was the centre of art, literature, and learning. After the extinction of the imperial Swabian (Hohenstaufen) line the dignity of duke of Swabia remained in abeyance; the feudatories of the duchy asserted an immediate dependence upon the empire, and waged frequent wars one upon another. Of these minor states the most important and most powerful were the countships of Würtemberg and Baden. The towns and cities, very many of which enjoyed the freedom of the empire, preserved a strong feeling for independence and a no less strong feeling of opposition to the feudal lords. In 1331 twenty-two towns (*Ulm, Reutlingen, Augsburg, Heilbronn,* &c.) united for purposes of mutual defence. Thirty years later many of the minor feudal lords formed a league to oppose the towns, and bloody feuds arose between the parties. The league of the feudal party was broken up by the Count of Würtemberg, the ally of the Swabian league (of towns), in the last years of the 14th century. Nevertheless feuds and violent dissensions still raged rampant, and even continued to do so after the emperor summoned all the parties concerned to a conference at Esslingen (1487), where *the* Swabian League was formed (1488) for the maintenance of peace throughout the old Swabian duchy. This unhappy region suffered terribly during the Peasant War (q.v.) of 1525, in the Thirty Years' War (1618–48), and during the wars of the French Revolution. From the time of the Reformation the rulers of Würtemberg contended with the German emperors for preponderance of power in what since the beginning of the 16th century was called the Circle of Swabia (one of the ten into which the empire was divided). The former proved the stronger in the long run, and in 1806 founded the modern kingdom of Würtemberg, which embraces the greater part of the old duchy.

The *Swabian School,* in German literature, indicates a band of writers who were natives of Swabia (as Uhland, Schwab, Kerner, Mörike, Hauff, and others). For the *Swabian Alb,* see WÜRTEMBERG.

Swaffham, a market-town of Norfolk, 15 miles SE. of Lynn. It has a cruciform Perpendicular church (1474) of great beauty, a corn-hall (1858), and an ugly market-cross (1783). Pop. (1851) 3858; (1891) 3636.

Swahili (Arab. *Waswahili,* 'coast people'), the name given to the people of Zanzibar and the opposite coast belonging to the Bantu stock, with an Arab infusion, and speaking a Bantu tongue modified by Arabic. The Swahili are intelligent and enterprising, and are in demand as porters by travellers into Central Africa. There is a collection of Swahili Folk-tales (1869) and a handbook by Bishop Steere (1871; new ed. 1875), and a dictionary by Krapf (1882).

Swale, a river in the North Riding of Yorkshire, flowing 60 miles ESE., and near Aldborough uniting with the Ure to form the Ouse (q.v.).

Swallow, a genus (Hirundo) and family (Hirundinidæ) of Passerine birds. The members of this family are distinguished by their long and pointed wings, long head, slender wide bill, small legs and feet, tarsus scutellated in front, and tail generally forked. They have no autumn moult, but acquire their new dress in February; hence Seebohm thinks they are a recent import from the south which, like some shrikes, have changed their breeding time, but have not yet altered their moulting time. The genus Hirundo is cosmopolitan in distribution, and contains about sixty species. The members are gregarious, and prefer well-cultivated districts and the proximity of water. They have great powers of flight and perch but little, catching their prey, which consists chiefly of insects, on the wing. Their usual note is a twitter, but some species sing sweetly. Their nests are built of mud, straw, and feathers, on ledges under eaves, on rocks, in caves, and in holes in earthy cliffs. Five species are found in Europe, and three are migrants to the British Isles. The Common Swallow, or Chimney-swallow (*Hirundo rustica*), is distributed in Europe, Asia, and Africa, from Lapland to the Cape of Good Hope and to the Moluccas. It breeds in the Orkney and Shetland Islands, and straggles to Iceland, Spitzbergen, and Nova Zembla, but does not reach America. It exhibits a character common to many other species, in the very long and deeply-forked tail, the two lateral feathers of which far exceed the others in length. The plumage is very beautiful, the upper parts and a band across the breast glossy bluish black, the forehead and throat chestnut, the lower parts white, and a patch of white on the inner web of each of the tail-feathers except the two middle ones. The whole length of the bird is about 8 inches, of which the outer tail-feathers make 5 inches. The female has a shorter tail, less chestnut on the forehead, and whiter under parts. The nest, probably originally built in caves, is made of mud or clay, formed into little pellets and stuck together, along with straw and bents, and lined with feathers. It is open and cup-shaped, and is generally placed in a situation where it is sheltered from wind and rain, as a few feet down an unused chimney, under the roof of an open shed, or in any unoccupied building to which access can be obtained. From four to six eggs are laid, blotched and speckled with shades of gray and brown. Two broods are produced in a year. Large flocks collect together in autumn before they depart for the south. Some birds, probably belated individuals, have been found in a torpid state in winter. A popular delusion, shared in by Johnson, credited swallows with hibernating regularly under water. The Window-swallow, or House-martin (*H. urbica*, or *Chelidon urbica*), is another very common British species, glossy bluish black above, white below and on the rump; the feet covered with short, downy white feathers. Its length is a little over 5 inches; the sexes are alike in plumage. The nest is built of mud or clay, like that of the chimney-swallow, but is hemispherical, with the entrance on the side, and is attached to a rock, or, very frequently, to the wall of a house, under the eaves or in the upper angle of a window. Two or even three broods are produced in a season, and the old birds return year after year to nest in the same spot. House-martins congregate in great numbers, as the chimney-swallows do, before their autumn migration, and disappear all at once. The only other common British species of swallow is the Sand-martin (*H. riparia*), smaller than the two preceding and arriving before them. It has the toes naked, the tail moderately forked, the plumage brown on the upper parts and across the breast, the under parts white. It makes its nest in sandy river-banks, the sides of sand-pits, and other such situations (even the turf-covered roofs of peasants' houses in Norway), excavating a gallery of 18 inches or 2 feet, sometimes 3 or even 5 feet in length, and more or less tortuous, in the slightly dilated extremity of which some soft material is placed for the reception of the eggs. This wonderful excavation is accomplished entirely by the bill of the bird. The floor slopes a little upwards from the entrance, so that the lodgment of rain is prevented. The sand-martin, on account of the nature of its haunts, is somewhat more local than the other British swallows; but it is distributed over most parts of Europe, Asia, Africa, North America, and South America to the Amazon valley. The Purple Swallow, or Purple Martin (*H.* or *Progne purpurea*), is a North American species, which is said to have visited the British islands. The general colour, both of the upper and under parts, is shining purplish blue; the wings and tail black. It abounds in North America, and is a universal favourite in the northern parts, being hailed as the harbinger of spring, and frequenting even the streets of towns. It is a very general practice to place boxes near houses for the martins to make their nests in, which are very inartificial, consisting merely of dried grass, leaves, moss, feathers, and the like. Boxes nailed to trees are also readily occupied by the Rufous-bellied Swallow (*H. erythrogaster*), another North American species. But this species, which very nearly resembles the chimney-swallow of Britain, makes a nest of mud and fine hay, in the form of the half of an inverted cone, with an extension at the top, for one of the parent birds to sit in occasionally. The Republican

Swallow, or Cliff-swallow (*Petrochelidon lunifrons*), of North America, makes a nest of mud, in form somewhat like a Florence flask, which it attaches to a rock or to the wall of a house. Hundreds sometimes build their nests in close proximity. The Fairy-martin (*H. ariel*), a small Australian species, also builds a flask-shaped nest with the mouth below, attaching it to a rock, or to the wall of a house; and numerous nests are often built close together. Another Australian species (*Petrochelidon nigricans*) lays its eggs in a hollow tree or rock without any nesting material. Some of the swallows of tropical countries are much smaller than any of the European species. See SWIFT.

Swammerdam, JAN, entomologist and anatomist, born at Amsterdam, 12th February 1637, showed almost from his boyhood the greatest zeal in the study of natural history. Choosing medicine for his profession, he was trained at Leyden, and settled down to practise in Amsterdam. But he gave far more time and attention to investigating the life-history and anatomical structures of insects than to his calling, became straitened for means, and finally was carried away by the religious mysticism of Antoinette Bourignon (q.v.). He died at Amsterdam on 17th February 1680. His chief services in the advancement of science were the application of a method of studying the circulatory system by injections of hot wax, demonstrations in the anatomy of bees and other insects, and investigations into the metamorphoses of insects, the results of which afforded sure groundwork for subsequent classification. His most important books were *General Treatise on Bloodless Animalcules* (in Dutch, Utrecht, 1669) and *Biblia Naturæ* (ed. Boerhaave, 1737-38), giving the results of his researches in insect anatomy.

Swan (*Cygnus*), a genus of birds constituting a very distinct section of the Duck (q.v.) family Anatidæ. They have a bill about as long as the head, of equal breadth throughout, higher than wide at the base, with a soft cere, the nostrils placed about the middle; the neck longer than the body, arched, and with twenty-three vertebræ; the legs short and placed far back; the front toes fully webbed, the hind toe without membrane; the keel of the breast-bone very large; the intestines very long, and with very long cæca. They feed chiefly on vegetable substances, as the seeds and roots of aquatic plants, but also on fish spawn, of which they are great destroyers. They are the largest of the Anatidæ. They have a hissing note like geese, which they emit when offended, and they deal tremendous blows with their wings in attack or defence. The Common Swan, Mute Swan, or Tame Swan (*C. olor*) is about 5 feet in entire length, and weighs about 30 lb. It is known to live for at least fifty years. The male is larger than the female. The adults of both sexes are pure white, with a reddish bill; the young (cygnets) have a dark bluish-gray plumage and lead-coloured bill. The bill is surmounted by a black knob at the base of the upper mandible, and has a black nail at its tip. In its wild state this species is found in the eastern parts of Europe and in Asia as far as Mongolia and the north-west of India, breeding in Denmark, the south of Sweden, in central and southern Russia, and in Turkestan; in a half-domesticated state it has long been a common ornament of ponds, lakes, and rivers in all parts of Europe. It is said to have been brought to England from Cyprus by Richard I. It is perhaps the most beautiful of water-birds, when seen swimming, with wings partially elevated, as if to catch the wind, and finely-curving neck. The ancients called the swan the Bird of Apollo or of Orpheus, and ascribed to it remarkable musical powers, which it was supposed to exercise particularly when its death approached. The note of the male bird at breeding time is loud and trumpet-like; the tame bird's note is little more than a hiss. The nest of the swan is a large mass of reeds and rushes, near the edge of the water, an islet being generally preferred. The female begins as a rule to lay in her second year from three to five eggs; when older she lays ten to twelve eggs, of a dull greenish-white colour. These birds are said to pair for life. The female swan sometimes swims about with the unfledged young on her back; and the young continue with their parents till the next spring. The swan is now seldom used in Britain as an article of food, but in former times it was served up at every great feast, and old books are very particular in directions how to roast it and to prepare proper gravy. The Polish Swan (*C. immutabilis* of Yarrell) is generally believed now to be a mere variety of the common swan. The Whistling Swan, Elk Swan, or Whooper (*C. ferus* or *musicus*) abounds in the northern parts of Europe and Asia, but to Britain it is now merely a cold-season migrant from more northern regions, although about a century ago it used to breed in the Orkneys. The size is about equal to that of the common swan, and the colour is similar, but the bill is more slender, is destitute of a knob, and is depressed and black at the tip and yellow at the base. This bird is frequently brought to the London market. The names whooper and whistling swan are derived from the voice. Like all swans of the northern hemisphere, except the common swan, this one has a large cavity in the interior of the breast-bone in which the windpipe coils before passing to the lungs. Bewick's Swan (*C. bewicki*), another native of northern Europe, is more rare in Britain, but large flocks are sometimes seen. It is about one-third smaller than the whistling swan. The American Swan (*C. americanus*), closely resembling Bewick's swan but larger, is sometimes found in Britain. It breeds in the northern parts of North America, but its winter migrations extend only to North Carolina. The Trumpeter Swan (*C. buccinator*) is another American species, breeding chiefly within the Arctic Circle, but of which large flocks may be seen in winter as far south as Texas. It is rather smaller than the common swan. The ancients spoke of a black swan proverbially as a thing of which the existence was not to be supposed, but Australia produces a Black Swan (*C. atratus*), discovered towards the end of the 18th century, rather smaller than the common swan, the plumage deep black, except the primaries of the wings, which are white. The neck is long, thin, and

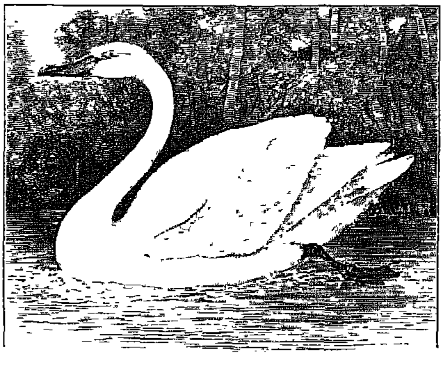

Fig. 1.—Wild Swan, or Whooper (*Cygnus ferus*).

gracefully curved. The eye is red. The bill is vivid carmine, with a white cross band. It has been entirely acclimatised in the northern hemisphere. The Black-necked Swan (*C. nigricollis*), perhaps the handsomest bird of the genus, is a South American species, ranging from Chili across the continent and southwards to Tierra del Fuego and the Falkland Islands. The Duck-billed Swan (*C. anatoides*), the smallest of all the species, common about the Strait of Magellan, has the head and neck velvety seal brown of the darkest shade, and the rest of the plumage of the purest white. It is curious that the black colour appears more or less in all the species of the southern hemisphere, and in them alone, except in the approach to it made in the cygnets of the north.

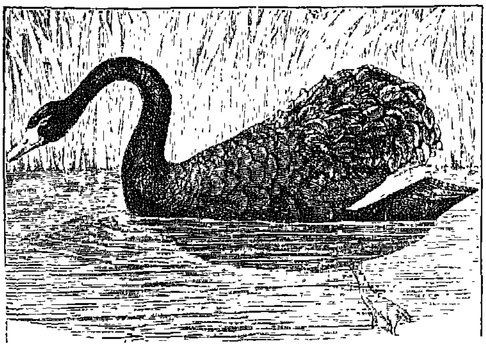

Fig. 2.—Black Swan (*Cygnus atratus*).

Swans, according to the law of England, are birds-royal. When they are found in a partially wild state, on the sea and navigable rivers, they are presumed to belong to the crown, and this is one of the prerogatives of the crown, though it may be delegated to a subject. The royal birds generally have a 'nick' or mark on them, and the king's swanherd once was an important person. A subject is not entitled to have a swan-mark unless he has a qualification of land, and has a grant from the crown, or prescriptive use. But any person may have swans in his grounds in a tame state, and then he has a property in them. Whoever steals or destroys swans' eggs forfeits 5s. for every egg, and whoever steals a marked swan of the crown, or a tame swan, commits felony. The most famous British swannery is that of Abbotsbury in Dorsetshire, 8 miles NW. of Weymouth, though the number of its swans has diminished from 6000 or 7000 to 1000.

Swanage, a pleasant little watering-place of Dorsetshire, in the 'Isle' of Purbeck, nestling in the southern curve of a lovely bay, 9½ miles SE. of Wareham, but 11 by a branch-line opened in 1885. In Swanage Bay, in 877, King Alfred won England's first naval victory—a defeat of the Danes. Pop. of parish, 2357. See PURBECK, and J. Braye's *Swanage* (1890).

Swansea (Welsh *Abertawe*), a seaport of Glamorganshire, South Wales, on the banks and at the mouth of the river Tawe, 45 miles WNW. of Cardiff and 216 W. of London. A municipal, parliamentary, and also (since 1888) county borough, it is the most important town in South Wales. Its rapid progress depends on the manufacture of tinplate here and in the neighbourhood; on its harbour and docks, which afford every convenience for the largest vessels and steamships afloat; and on its geographical position, on a bay affording a spacious, sheltered, and safe anchorage, several hours nearer the open sea than any other port of comparable size in the Bristol Channel. The Harbour Trust of Swansea, with a capital of £1,500,000 and an income of upwards of £100,000 per annum, possesses docks, constructed since 1847, covering an area of over 60 acres. There is annually manufactured in Swansea and the immediate neighbourhood upwards of two-thirds of the tinplates manufactured in Britain, representing a value of upwards of £5,000,000. There is still a large direct export trade to America in tin and (the inferior) terne plates, though this branch of trade was much injured by the McKinley tariff legislation of 1890. The imports in 1890 had a value of £5,007,073, the chief items being copper, silver, lead, tin, and nickel, with their ores and alloys (£2,030,142), iron and steel in various forms (£461,082), iron ore (£113,718), zinc, sulphur, phosphates, flour, grain, esparto, timber, bricks, &c. The exports had a value of £7,220,735, including tin, terne, and black plates to the value of £3,446,865; coal and coke (£1,041,769); copper, zinc, and their ores (£1,077,775); iron and steel, alkali, superphosphate, arsenic, &c. Pop. of municipal borough (1851) 31,461; (1881) 65,597; (1891) 90,423. Since 1885 Swansea returns two members to parliament, one for the district division (Aberavon, Kenfig, Loughor, and Neath). The charter dates from the days of King John and Henry III., renewed by subsequent sovereigns. The castle, of which a tower still remains, was founded in 1099 by the Earl of Warwick, but in the reign of Edward IV. passed by marriage from the Herberts to the Somerset family, and is still the property of the Dukes of Beaufort. The grammar-school dates from 1682.
